Lake Taihu, the second largest freshwater lake in China, plays a significant role in protecting water resources and maintaining ecological balance. In recent decades, with the rapid development of industry and agriculture, the continuous increase of population and the constant expansion of urbanization, Lake Taihu was faced with increasingly severe environmental problems, including water quality deterioration and eutrophication. In May, 2007, an estimated 4 million people in Wuxi, an industrial city located along the lake, were deprived of drinking water for nearly a week, as a carpet of algae scum or agglomerate of biological origin made local lake water unusable [1] [2]. Nutrient is the major factor leading to eutrophication, therefore, quantitative assessment of nutrient loads in Lake Taihu is of great importance for putting forward reasonable and effective eutrophication control measures. To date, many studies have been conducted on nutrient loads of Lake Taihu from a certain source, such as river runoff [3], atmospheric bulk deposition [4] and internal release [5]. These studies did gain some fruits, but few studies have simultaneously considered both transverse and vertical sources of nutrients to Lake Taihu. In this paper, we selected 2011 as a typical year to quantitatively analyze the spatial and temporal variation characteristics of nutrient loads of Lake Taihu from the sources of transverse river runoff, vertical atmospheric bulk deposition and internal release on the basis of field measurements and laboratory experiments, so as to find out the distribution of the nutrient loads of Lake Taihu. The results have great significance for eutrophication control and water environment protection in Lake Taihu.

Study Area

Lake Taihu is located in the lower Yangtze River delta between 30°56′-31°33′N and 119°53′-120°36′E. The lake is characterized by flat terrain, like a dish, which is a typical shallow lake. Lake Taihu has an area of 2338km^2 and a catchment area of 36,500 km^2, with an average depth of 1.89m. Taihu Basin belongs to subtropical monsoon climatic region, with an average temperature of 15-17 ºC, an average annual precipitation of 950-1250mm, and an average wind speed of 3.5-5 m/s. Taihu Basin has a complex and high density set of river networks. Rivers surrounding Lake Taihu flow in and out through five hydraulic areas including Huxi area, Zhexi area, Hangjiahu area, Wuchengxiyu area and Yangchengdianmao area (Figure 1).

Fig.1. Map of Lake Taihu

Transverse Nutrient Loads

TN or TP load discharged to the lake for each month was calculated by the following formula:

$$W = \sum_{i=1}^{n} C_i \cdot Q_i \quad (1)$$

Where W is nutrients of river input or onuput, t/a; C_i is water quantity concentration of hydraulic area I, mg/L, data were obtained from monitoring data of 72 inflow rivers of Lake Taihu; Qi is flow value of hydraulic area I, m^3/s, data were obtained from the Taihu Basin Authority of Ministry of Water Resources.

River inputs. Using this approach, we calculated annual inputs fluxes of 2382.4 tons TP and 50245.0 tons TN from the rivers surrounding lake draining into Lake Taihu in 2011. TP loads discharged from Huxi area, Zhexi area, Hangjiahu area, Wuchengxiyu area and Yangchengdianmao area were respectively 1706.6 tons, 285.2 tons, 50.3 tons, 317.7 tons and 22.6 tons, accounting for 71.6%, 12.0%, 2.1%, 13.3% and 0.9%. In contrast, TN loads discharged from the five areas were respectively 33283.9 tons, 4711.8 tons, 630.2 tons, 10612.2 tons and 1006.9 tons, accounting for 0.7%, 14.2%, 12.5%, 23.5% and 49.0%. Nutrients inputs from five areas in different month are shown in Figure 2.

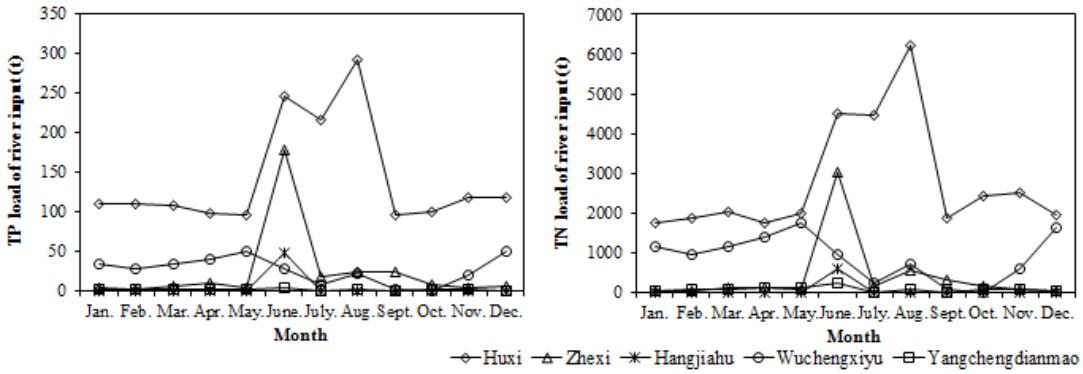

Fig.2. Distribution of river nutrients inputs in 2011

River outputs. Using this approach, we calculated annual outputs fluxes of 849.1 tons TP and 24236.7 tons TN from the rivers surrounding lake flowing out Lake Taihu in 2011. TP loads outputted from Huxi area, Zhexi area, Hangjiahu area, Wuchengxiyu area and Yangchengdianmao area were respectively 7.6 tons, 204.3 tons, 272.0 tons, 151.4 tons and 213.8 tons, accounting for 0.9%, 24.1%, 32.0%, 17.8% and 25.2%. In contrast, TN loads outputted from the five areas were respectively 171.8 tons, 3437.1 tons, 3038.2 tons, 5705.4 tons and 11884.3 tons, accounting for 0.7%, 14.2%, 12.5%, 23.5% and 49.0%. Nutrients outputs from five areas in different month are shown in Fig.3.

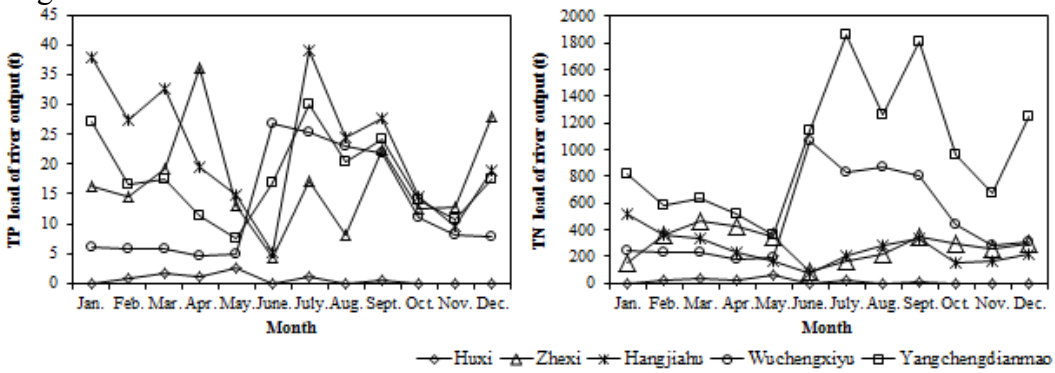

Fig.3. Distribution of river nutrients outputs in 2011

Vertical Nutrient Loads

Atmospheric bulk deposition. The surface area of Lake Taihu is large. The concentrations of TN and TP from atmospheric bulk deposition are quietly high, which may lead to a series of influences on eutrophication and water ecosystem structure. Therefore, atmospheric bulk deposition is also an important source of nutrients to Lake Taihu. The calculation formula of nutrient loads to lake from atmospheric bulk deposition is as follows:

$$Q = Q_d + Q_w = \Sigma F_{di} \times S_i \times d_i / S + \Sigma F_{wi} \times S_i / S \quad (2)$$

Where Q is the deposition fluxes of TP or TN, kg/a; Q_d, Q_w are the fluxes of dry and wet deposition, kg/a; F_{di}, F_{wi} are atmospheric deposition rate of dry and wet deposition in different sampling site, kg/(km^2·d); S_i is the area of each sampling site, km^2; d_i is the dry deposition days of each sampling site in a year, day; S is the surface area of Lake Taihu, km^2.

Based on the rainfall statistics of 2011 and the experiments of dry and wet deposition [7], we calculated the dry and wet deposition fluxes of nutrients in different seasons according to the formula (2), then estimated the deposition fluxes of each month according to the monthly rainfall, as shown in Figure 4. We found that the deposition fluxes in summer (June to August) is relatively high, which TP and TN respectively accounted for 71.9% and 44.6% of annual deposition fluxes.

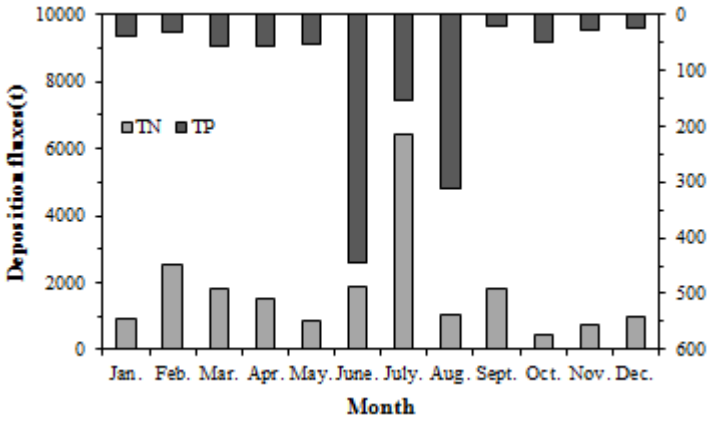

Fig.4. Distribution of nutrients from atmospheric bulk deposition in 2011

Internal release. Lake Taihu is a large shallow lake. Due to disturbance of wind waves, nutrients release and absorb along with the complex movement of sedimentation and resuspension of sediment. When the wind speed is small or the lake is calm, the resuspension flux of sediment is slight or few that it has little effect on the concentration of water quality. When the wind speed comes to the critical wind velocity of sediment resuspension, the sediment resuspension is evident, a lot of nutrients were brought into water. Nutrient loads from internal release to lake are the difference between resuspension fluxes and sedimentation fluxes, the calculation formulas of nutrient loads to lake from internal release are as follows:

$$Q = Q_r - Q_s \tag{3}$$

$$Q_r = S \cdot \sum_{i=1}^{n} (M_i \cdot T_i) \tag{4}$$

$$Q_s = S \cdot \sum_{i=1}^{n} (N_i \cdot T_i) \tag{5}$$

Where Q_r is the nutrients fluxes of resuspension, ton; Q_s is the nutrients fluxes of sedimentation, ton; S is the distribution area of sediment, m^2; M_i is the release rate of each factor under different wind speeds, $g \cdot m^{-2} \cdot d^{-1}$; Ti is the duration time of different wind speeds, day; N_i is the average sedimentation rate under different wind speeds, $g \cdot m^{-2} \cdot d^{-1}$.

The distribution area of sediment in Lake Taihu is 1632.9 km^2 [8]. The average release rate and the average sedimentation rate of nutrients under different wind speeds were obtained from sediment experiment in the laboratory [9]. Based on the above results and wind speed data of Lake Taihu in 2011 (from Taihu Basin Authority), we applied a two-dimensional mathematical model of water quantity and quality to calculate monthly nutrients fluxes to Lake Taihu from internal release (Figure 5). Results showed that: TN and TP loads from internal release were respectively 1020.6 tons and 505.3 tons in 2011, and the nutrients fluxes of internal release were larger in August, September and December.

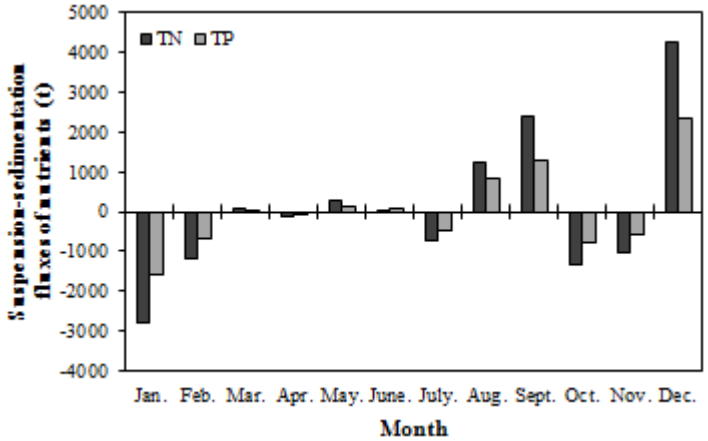

Fig.5. Distribution of nutrients from internal release in 2011

Total nutrient loads

Based on the calculation results of nutrient loads from transverse river runoff, vertical atmospheric bulk deposition and internal release, we calculated total nutrients fluxes of 3306.6 metric tons TP and 48007.0 metric tons TN from the sources to Lake Taihu in 2011.

In terms of space, TP loads from the sources of river runoff, atmospheric bulk deposition and internal release were 1533.3 tons, 1268.0 tons and 505.3 tons in 2011, accounting for 46.3%, 38.3% and 15.4% respectively; TN loads were 26008.4 tons, 20978.0 tons and 1020.6 tons, accounting for 54.2%, 43.7% and 2.1%, respectively (Figure 6). The results indicated that atmospheric bulk deposition and internal release were the major sources of nutrient loads besides river runoff, and nutrients pollution from vertical sources should also be taken into consideration and controlled. Meanwhile, Huxi area was the major source of nutrient loads for its TP and TN loads accounted for 71.6% and 66.2% respectively, so the treatment and governance of pollution sources in Huxi area should be strengthened.

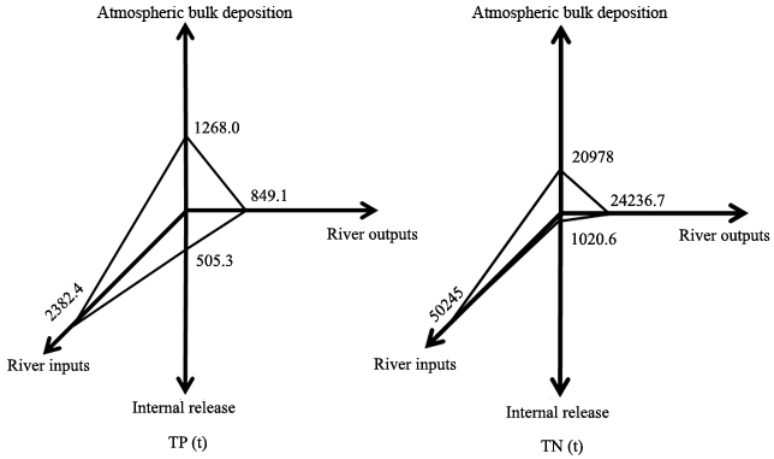

Fig.6. Spatial distribution of nutrient loads of Lake Taihu

In terms of time, nutrients loads from different sources in each month were shown in Figure 7. Nutrients loads from internal release in some months were negative as the sedimentation fluxes were larger than resuspension fluxes, and it may cause nutrient loads from all the sources to be negative, for example nutrient loads in January and October. TN loads in June, July, August and December were relatively higher which respectively were 8874.9 tons, 7463.3 tons, 7181.3 tons and 6856.9 tons, and TP loads in June, August, September and December were relative higher which respectively were 983.9 tons, 1420.9 tons, 1347.1 tons and 2448.5 tons, so nutrient loads of Lake Taihu were higher in summer (June to August), it can replenish the nutrients for the growth of algae and aquatic plants, and played a facilitating role in algae blooms.

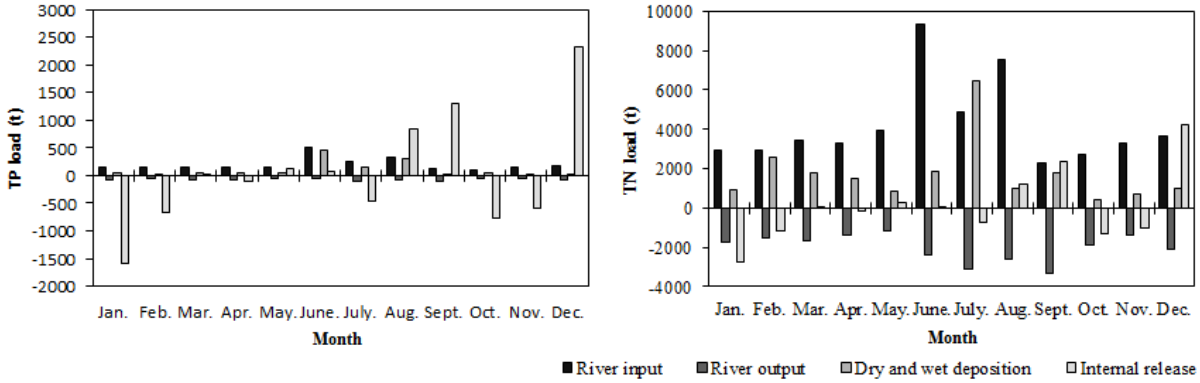

Fig.7. Temporal distribution of nutrient loads of Lake Taihu

Conclusions

In this paper, based on measured data and laboratory experiments, we quantitatively calculated nutrient loads of Lake Taihu in 2011 from the sources of transverse river runoff, vertical

atmospheric bulk deposition and internal release, and analyzed the spatial and temporal variation characteristics of nutrient loads. TP and TN loads of Lake Taihu in 2011 were 3306.6 tons and 48007.0 tons. Huxi area was the major transverse source of nutrients as a large proportion of TP (71.6%) and TN (66.2%), so the treatment and governance of pollution sources in Huxi area should be strengthened. Atmospheric bulk deposition and internal release were the major sources of nutrient loads besides river runoff as accounted for 38.3% and 15.4% of TP, and accounted for 43.7% and 2.1% of TN, respectively. Nutrient loads were higher in summer (June to August), so it can replenish the nutrients for the growth of algae and aquatic plants, and played a facilitating role in algae blooms. This paper was helpful to accurately grasp nutrient loads of Lake Taihu and propose targeted total amount control plan, so as to provide guidance for water environmental protection in Lake Taihu.

Keywords: soil invertase; Urease; Catalase; Tea garden

Abstract. Enzyme activities play key roles in the biochemical functioning of soils, including soil organic matter formation, degradation and nutrient cycling. Activities of invertase, urease, and catalase were analyzed at different age of tea garden. The results showed that urease activity only showed a significantly negative relationship with the age of tea, and a significant positive relationship with organic carbon. This indicated that soil urease acitivity could respond well to the change of soil organic carbon and is a more sensitive indicator of soil fertility than other enzyme activities. The study also found that the organic carbon was relatively low in 50yr site, compared with lower age of sites. This may be caused by the high activities of invertase and catalase per unit of organic carbon in the soil of tea which tends to help decompose and therefore decrease the organic carbon in soil

Introduction

Soil enzymes play an essential role in nutrient mineralization and the decomposition of organic matter, their activities are key drivers of nutrient suppliy to plants[1]. Soil enzymes involved in carbon, nitrogen, phosphorus transformation. They would intergrate chemical, physical and biological charateristics and are sensitive to environmental stress and respond rapidly to change in land management[2]. Soil invertase and urease have been showed to be significantly higher in tilled soils than in cultivated soil[3]. These soil enzyme acitivites are also higher in crop rotations than in monocultures[3].Therefore, there is currently great interest in the use of extracellular enzyme activites as biological indicators of soil quality.

Tea (Camellia sinensis L.) is an intensively managed perennial evergreen broad-leaved cash crop. Tea gardent area covers approximately three million hectares of the world' arable land [4]. Xue et al [5] reported the change in acid red soil enzyme activities of tea garden, However, little is known about the change in soil enzyme acitivities of other soils within tea garden with time. Better understanding of enzyme acitivities in other soil could lead to more effectways of elucidating the action of tea system in improving soil fertility. This also is vital for understanding soil quality in the sustainability of tea plantation productivity.

Materials and Methods

We conducted this study at Shazhenxi, Zigui, Yichang, Hubei Province China, approximately 30km upstream to the three Gorges Dam and Adjacent to the Three Gorges Reservoir. The site is located between latitude 30°55′04.8″N and 30°55′10.2″N; longitude is between 110°41′25.2″E and 110°41′51.2″E and altitude between 236 m and 267 m above sea level, and belongs to the humid subtropical monsoon climate zone with warm winters, early springs, hot and dry summers, and rainy, humid, foggy autumns. The rainfall in this area is abundant with an annual average 1100mm

while having an uneven temporal and spatial distribution. The soil parent material at all investigated sites are purple soil.

In the study area, three different ages of tea sites were selected (ie. 6-, 15-, and 50-year).

Table 1 Status of experimental plots

year	Water content(%)	Bulk density ($g.cm^{-3}$)	Organic C($g.kg^{-1}$)	Total N($g.kg^{-1}$)	C/N
6	31.28	1.53	4.62	0.15	30.8
15	35.26	1.61	4.03	0.16	25.19
50	25.24	1.95	2.63	0.13	20.23

Soil sampling

Soil samples (0–20 cm and 20-40cm depth) were collected in July 2008 from three random sampling quadrat (5m×5 m) at each site described above. In each quadrat the soil was collected from five points randomly, and mixed into one sample. After carefully removing the surface organic materials and fine roots, each mixed soil sample was was air-dried for the estimation of soil enzyme activities.

Invertase activity was determined after incubating the sample with 35.06mM sucrose, as substrate, for 3 h at 50℃,with 2M acetate buffer ph 5.5, the reducing sugars released were determined following the method of Schinner and von Mersi [6].

Urease activity was measured according to Kandeler and Gerber[7]. 1g DW soil was mixed with 1.75ml of 100Mm borate buffer (Ph 10.0) and 0.25ml of 820Mm urea. The mixture was then incubated at 37℃ for 1h and the reaction stopped with 6ml of acidified 2M KCl. After centrifugation (3500×g, 3min), 0.25ml of the supernatant fraction was mixed with 3.75ml of distilled water and 2ml of a reagent composed of a sodium salicylate/sodium nitroprusiate mixture(17%, w/v and 0.12%, w/v, respectively), 0.3M NaOH, and distilled water (1:1:1, v/v/v). Finally, 0.8ml of sodium dichloroisocyanurate was added to the reaction mixture. After 30min, the absorbance value of the sampled was read at 670nm.

Soil catalase was tested by the Roberge method[8], with slight modifications. Two grams sir-dried soil with 40ml distilled water and 5ml 0.3% H_2O_2, was shaken for 20min (shaking velocity was 150rpm) and filtered immediately. The filtrate was titrated with 0.1mol l^{-1} $KMnO_4$ in the presence of sulphuric acid and the results were expressed as umol $KMnO_4$ $g^{-1}h^{-1}$.

Statistical analysis

All statistical work was done using the SPSS 13.0 for Windows. One-way ANOVA was used to analyze means of age, to least significant difference at the 5% level. When significance is observed at the $p < 0.05$ level, Tukey's post hoc test was used to carry out multiple comparisons. Pearson's test was used to determine whether there was significant correlation between soil enzyme activities and soil organic matter.

Results and Discussions

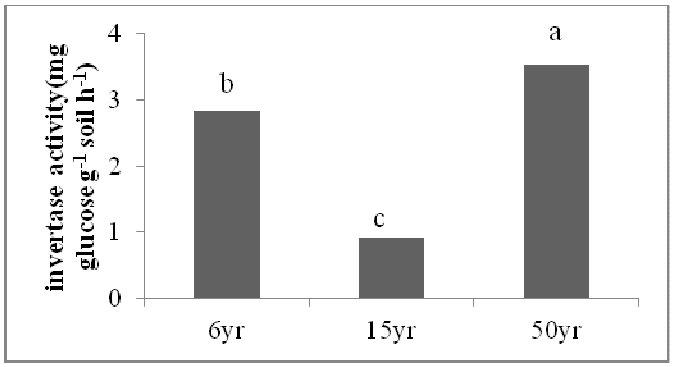

Fig.1 The change in soil invertase activity with the age of tea

For carbon cycle enzyme, invertase catalyses the hydrolysis of sucrose to D-Glucose and D-fructose. Soil invertase activity was highest under 50yr sites and lowest under 15yr site, respectively. This was consistent with Xue et al[5] which showed the 50-year-old tea orchard red soil had a comparatively higher invertase activity compared to the 8- and 90-year-old tea orchard red soil. Invertase had no significantly relationship with organic matter. This was inconsistent with Guan[9]that all kinds of enzyme activities were positively related to organic matter content.

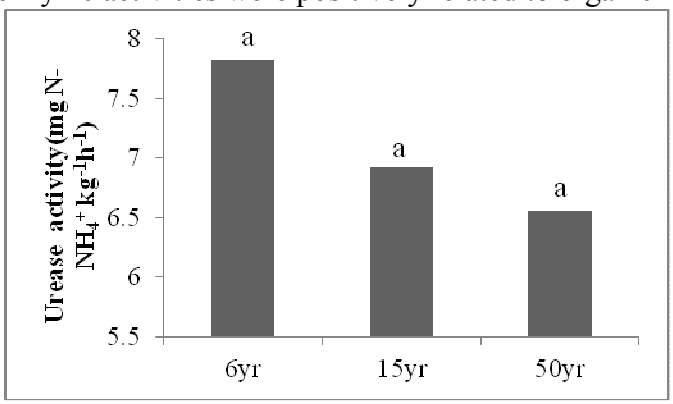

Fig. 2 The change in soil urease activity with the age of tea

For nitrogen cycle enzyme, urease is involved in the hydrolysis of urea-type substrates to CO_2 and NH_3 and its activity is crucial in the transformation of urea fertilizer. Most of the variation in urease activity among soils can be accounted for by the quantity of soil organic matter[10]. Therefore, understanding of urease activity dynamics could reveal more effective ways of managing N fertilizers [11]. In this study, although one-way ANOVA analysis showed that there was no significant difference among three sites, the age of tea had a significantly negative relationship with urease activity. Futhermore, there was a significantly positive relationship between urease activity and organic C. This was consistent with Pettit et al[12]and Rodríguez-Loinaz et al[13]. Rodríguez-Loinaz et al[13]also found that urease activity was positively correlated with organic matter content.

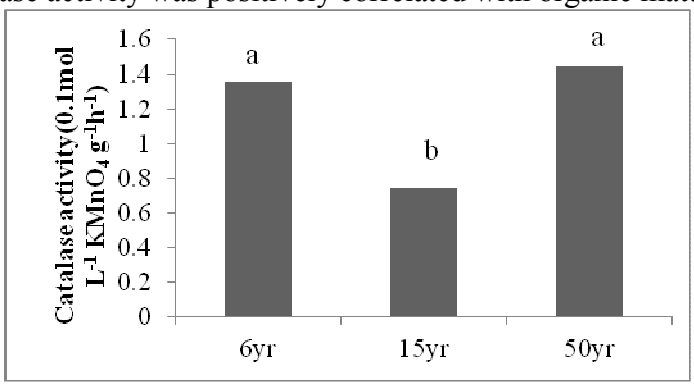

Fig. 3 The change in soil catalase activity with the age of tea

Among the oxidoreductase enzyme systems, soil catalase can also be used as a measure of biological activity. This is possible because soil catalase, although acting mainly as intracellular enzyme, remains active outside microbial cells because of an association with soil organic matter and/ or sorption on clay minerals[14,15]. Catalase splits hydrogen peroxide into molecular oxygen and water and keeps cells from damage caused by reactive oxygen species. In this study, catalase activity was similar to invertase acitivity, was highest under 50yr site and lowest under 15yr site, respectively. The increase in soil catalase activity could affect soil solution chemistry and change soil redox conditions. The change in soil solution had the potential to dissociate bonds between metals and complex organic matter and therefore alter soil storage[16]. Therefore, catalase could significantly influence on changing soil redox, chemical properites of soil dolution, and accelerating transformation of organic matte[16]. However, catalase showed no significant relationship with organic carbon and age of tea. This was inconsistent with Alef and Nannipieri[17]. Alef and Nannipieri[17] reported that catalase acitivity was very stable in soil and showed a significant correlation with the content of organic carbon. In addition, soil organic carbon was relatively low in 50yr site, compared with lower age of sites. This may be caused by the high activities of invertase

and catalase per unit of organic carbon in the soil of tea which tends to help decompose and therefore decrease the organic carbon in soil(Wang et al., 2012).

Table 2 Correlations between soil enzyme activities and organic matter, and the age of tea

	Age	OC	TN	Invertase	Urease
OC	-0.97**				
TN	-0.51	0.64			
Invertase	0.26	-0.47	-0.70		
Urease	-0.97**	0.89*	0.36	-0.01	
Catalase	0.11	-0.33	-0.64	0.99**	0.14

** Correlation is significant at the 0.01 level (2-tailed).

* Correlation is significant at the 0.05 level (2-tailed).

Conclusion

Invertase and catalase activities firstly decreased, tended to be lowest under 15yr, then they increased again, whereas urease activity showed no significant change among three sites. The correlations analysis showed that only urease and organic acarbon was positively related, and no correlation between organic carbon and invertase activity or catalase activity was observed. This suggested that soil urease acitivity could respond well to the change of soil organic carbon and is a more sensitive indicator of soil fertility than other enzyme activities measured.

Conclusion

Based on the analysis of the mechanical theory as the foundation, designed the soccer robot pick the ball institutions optimal design process, found aim function, select design variables and the corresponding optimization algorithm to optimize a complete set of institutions. At last through the test to get the final performance parameters of the institution. Experiments show that the system has higher accuracy and stability, the new optimize pick the ball have design basic requirements, and achieved good ideal control effect.

Abstract. Physicochemical modeling of drainage water in the tailing dumps of Komsomolsky tin ore district in a wide temperature range from -10 to +45 °C obtained in the article let to find Eh-pH parameters of micropore solutions from which technogenic and hypergene minerals crystallize. The modeling was made for different ratios host rock – sulfides (95:5, 90:10, 80:20 and 60:40). Qualitative and quantitative ionic composition of the solutions was determined and their impact on the surface and ground water of the area was showed.

Introduction

Long lasting and intensive development of the mining industry in the Komsomolsky district during the last 70 years led to the presence of numerous ditches, pits, tunnels and tailing dumps. It contributed to the creation of mining technogenic system with area of dozens of acres where hypergene processes are activated due to the increase of contact surface of sulfides with the weathering agents.

There are two concentrating mills and three tailings dumps (their total area is 80.8 hectares) in the district. 41.5 million tons tailings were stockpiled here. The finely-dispersed tailings mass of Komsomolsky region consists of (%): vein quartz – 37.5, tourmaline – 12.1, host sedimentary rocks – 45 and sulfides (pyrite, pyrrhotite, arsenopyrite, chalcopyrite, galena and sphalerite) – 3.8. They contain the following useful components (g/t): Sn – 0.2, Cu – 0.46, Zn – 0.094, Pb – 0.123, Ag – 1.227, Bi – 0.03, As – 0.629.

Negative impact of mining systems on the ecosphere in general and on the hydrosphere in particular is shown in many literary sources [1-3 and others].

The main purpose of this work is to assess the impact of technogenic and hypergene processes on hydrosphere in three tailing dumps of the district in a wide temperature range from -10 to +45 ° C. Climatic characteristic of the district [4] shows the annual temperature change in a range from -40 to +40 ° C. It can greatly increases under sulfides oxidation, so the upper limit was taken five degrees higher. Based on the goal the following tasks were formulated: 1. to research the process of sulfides oxidation in three tailings of the district in the temperature range from -10 to +45 ° C; 2. to determine the composition of technogenic minerals crystallized from the solutions of drainage and slime waters; 3. to find the qualitative and quantitative composition of these waters; 4. to assess their impact on the hydrosphere of the district; 5. to verify the data obtained.

Research method

Physicochemical modeling of technogenic processes occurring in the mining waste was conducted through the "Selektor" PC program. It made possible calculation of the amounts of elements carried out from the tailing dumps into the hydrosphere. The method is based on the minimization of the

Gibbs energy and estimation of the total and metastable equilibrium in multicomponent heterogeneous systems.

In our previous work the modeling was performed at the temperature of +25 ºC [5]. In this research we consider a system with a pressure of 1 atm and temperature range from -10 to +45 ºC. The water-rock ratio was taken as 10:1. The annual rainfall (400-500 kg per 1 m^2) and the selected temperature range were taken into account in the modeling. Models were opened to the atmosphere. The chemical composition of the atmosphere (10 kg) was calculated by R. Horne [6]: Ar – 3.21, C – 0.11, N – 539.48, O – 144.85. 19 independent (Al, Ar, As, B, C, Ca, Cu, Fe, K, Mg, N, Na, Pb, S, Si, Zn, H, O, e) and 452 dependent components were included in the calculations, from which 360 are dissolved particles, 18 gases and 74 hypogene and hypergene minerals.

Results and discussion

Mining wastes are presented by pyrite, pyrrhotite, galena, sphalerite, arsenopyrite, chalcopyrite, quartz, tourmaline and other minerals. Modeling of sulfides oxidation in contact with the host rock was carried out for all three tailing dumps (Table 1). The waste composition varies in its different parts, therefore simulated system for each of them were made with ratios of host rock – sulfides 95:5, 90:10, 80:20 and 60:40. Hypergene minerals crystallized from concentrated solutions of these models are shown in the Table 2.

In the simulated system of Festivalnoye deposit tailing dump – copper-tin-type of Solnechnaya concentrating mill (SCM) solutions are similar and have pH values ranging from 6.02 to 12.12 and Eh – 0.59-0.83 volts. Some of them crystallize at all ratios (g): goethite, woodwardite, kaolinite, magnesite, gypsum, hydromuscovite, others – in all ratios, except 95:5 (g): scorodite and rostite. Other minerals crystallize only at a certain ratio (g): calcite (95:5), duftite (80:20 and 60:40), alunogen (80:20 and 60:40), starkeyite (60:40) and montmorillonite (90 10).

In the simulated system of Solnechnoye deposit tailing dump – tin mineralization type of Centralnaya concentrating mill (CCM) solutions are similar and have pH values ranging from 5.98 to 12.29 and Eh – 0.58-0.84volts. In this temperature range minerals of hypergenesis zone and weathering crust crystallize from such classes as oxides, hydroxides, sulfates, carbonate, silicates, and arsenates. These are minerals of the following cations (g): Fe (goethite and scorodite), Pb and Cu (duftite) and Al (kaolinite, alunogen and rostite), Cu and Al (woodwardite), Mg (starkeyite and magnesite), Ca (gypsum and calcite), K and Al (hydromuscovite), Mg, Al and Fe (montmorillonite).

In the simulated system of the third tailing dump where ore processing waste of tin-polymetallic ore type of Perevalnoe deposit were stockpiled parameters of the solutions are similar and have pH values ranging from 6.09 to 12.06 and Eh – 0.60-0.83 volts. In these systems the same hypergene minerals crystallize as in the previous ones but are distinguished by the quantitative characteristic (Table 2).

It should be noted that the amount of crystallized minerals in all systems is low at a negative temperature, but the mineralization of these solutions is very high. For example, in the models of CCM tailings dump it is 144-284, SCM – 142-280 and the third one – 146-287 g/l. With the temperature increase from 0 up to +20 °C mineralization of the solution becomes higher (g/l): at CCM tailings dump – from 21.08 to 22.21, but then decreases to 20.55, SOF – 20.37-21.63 – to 20.37, at the third one – 21.48-22.24 – to 21.89.

At temperatures below 0 °C the model contain water in a solid form (ice), the content of which varies from 85.18 to 90.07 g and its amount decreases with the increase of host rock and decrease of sulfides in the system. Crystallization of some minerals (scorodite, starkeyite and rostite) in the models occurs at subzero temperatures in a range from 0 to -10 ° C and the other ones (calcite, alunogen, woodwardite, duftite, montmorillonite) at positive numbers from 0 to +45 °C. Other minerals (goethite, kaolinite, gypsum, magnesite) crystallize in a large range from -10 to +45 °C, but their quantity in the case of negative temperature values is much lower than for the positive ones. Thus crystallization at low temperatures is difficult.

Ionic composition of the resulting solutions is presented by the following ions of sulfide elements: As_5^+, $CuCO_3^{2-}$, Cu^{2+}, $CuCO_3^0$, CuO^0, $CuOH^+$, $CuSO_4^0$, $H_2AsO_4^-$, $H_3AsO_4^0$, $HAsO_4^{2-}$, $HCuO_2^-$, $HFeO_2^0$, FeO^+, FeO_2^-, $FeOH^{2+}$, $HPbO_2^-$, HSO_4^-, $HZnO_2^-$, $Pb(CO_3)_2^{2-}$, $Pb(SO_4)_2^{2-}$, Pb^{2+}, $PbHCO_3^+$, $PbNO_3^+$, PbO^0, $PbOH^+$, $PbSO_4^0$, $Zn(CO_3)_2^{2-}$, $Zn(SO_4)_2^{2-}$, Zn^{2+}, $ZnCO_3^0$, $ZnHCO_3^+$, ZnO^0, $ZnOH^+$, $ZnSO_4^0$, SO_4^{2-}.

Verification made with ionic and mineral composition [1] and comparison of the element contents in the modeled solutions with hydrochemical data on the mine, slime, and drainage waters [2-3] proved the validity of the obtained results.

Conclusion

Physicochemical modeling of sulfides oxidation has shown that from highly concentrated solutions hypergene minerals of Fe, Cu, Pb, Al, Mg, K and Ca crystallize, that belong to sulfates, carbonates, silicates, arsenates, oxides, and hydroxides classes. The greatest amount of ore elements (Cu, Pb, Zn, S) in the solutions is observed at negative temperatures. In the range of positive temperatures elements content in the aqueous solutions is gradually reduced by an order or two. Simulated drainage water solutions of all tailing dumps are characterized by high concentration (g/l) of S to 9.6, Pb – 66.8, Zn – 53.6, As – 46.6 and Cu – 53.9. Total mineralization of the tailings solutions is (g/l): 20 to 397 for CCM, 21-462 for SCM and 20-428 – for 3rd one. If we estimate the impact of each individual tailing dump, the maximum hydrosphere damage is caused by SCM tailing dump and the minimum – by CCM. Total removal of elements from all three tailing dumps varies from 61 to 1287 g/l.

Physicochemical modeling of the main phases of the drained tailing dumps existence in Komsomolsky tin ore district carried out by authors in the temperature range from -10 to +45 °C gives a complete picture of the drainage water formation that flows into the surface water in a dangerous, untreated form. Hydrosphere is exposed to strong anthropogenic stress with S, Zn, Cu, Pb, Fe sulfides elements and B, Mg, K, Na, Ca, Si and Al host rocks elements.

Modeling allows assessing the condition of mining technogenic system in space and time, to receive new data for the parameters of modern technogenic minerals and to show their Eh-pH existence conditions.

Abstract. Modeling allowed us to show Eh-pH parameters of the technogenic mineral formation in the mining-industrial technogenic system of polymetallic ores of Dal'negorsk district, to study the process of the hypergene mineral crystallization from solutions, to consider the qualitative and quantitative ionic composition of solutions, to show the role of hypergenesis in the contamination of surface and ground waters of the area. The aim of this work is to estimate the action of the CCM tailing oxidation on the hydrosphere of the district using the method of physicochemical modeling. The results obtained testify to a significant evacuation of a wide range of elements of sulfide ores (Zn, Pb, Cu, As, S) and enclosing rocks (Si, Al, Mg, Ca, K, Na) from the CCM tailing dumps into the surface waters polluting the hydrosphere with them.

Introduction

At the present time, the problems of ecological consequences of the mining-concentrating industry are very urgent. In Dal'negorsk district this industry has been developing for more than a hundred years. More than 20 skarn and polymetal deposits are developed here by opened and closed way. In Dal'negorsk there are two Central Concentrating Mills (CCM), and at present one of them is working. It processes the sulfide polymetal ores, and its work resulted in the formation of two tailing dumps (old and new) in the Town neighborhood. The CCM old tailing dump was in operation to 1978, and then up to present a new one is being filled.

Quarries, ditches, places of stripping, adits, and tailing dumps, resulted from mining works, form the mining-industrial technogene system. Sulfides in this system become accessible for the weathering agents and are intensively oxidized producing highly concentrated micro-pore solutions, which give rise to the mining and drainage waters and from which abundant hypergene and technogene minerals are precipitated.

The aim of this work is to estimate the action of the CCM tailing oxidation on the hydrosphere of the district using the method of physicochemical modeling. To do this we posed the following tasks: elaboration of the physicochemical models of tailing oxidation and estimation of the tailing dump action on the hydrosphere using the results obtained.

Materials and methods

In our investigations we use the method of physicochemical modeling. The correspondence of the developed model with the study object is checked by verification. The model allows the objective estimation of geochemical processes proceeding in the tailing dumps, determination of the composition of the dissolved ions of chemical elements in the sulfide oxidation process, study of crystallization of hypergene and technogene minerals, and prediction of the object state in the future.

Physicochemical modeling of the technogenesis processes in the CCM tailing dumps was performed using the "Selector-Windows" program complex based on the minimization of Gibbs free energy.

In the authors' previous works [2, 3] such investigations were carried out for the thermodynamic system with 40 hypergene and technogene minerals. Later, in the literature the thermodynamic parameters were found for pyrargyrite, hisingerite, and hydrogoethite and were calculated (A.A. Tupitsin and V.A. Bychinsky, Siberian Branch of RAS) for fibroferrite and then were brought into the system. Besides, the models were added with hypogene minerals of sulfur, silver, and antimony: argentite, acanthite, and pyrargyrite, as in the wastes about 5 g/t of silver is found in the form of these sulfides. We studied the dependence of element behavior in the solution and the technogene mineral crystallization on the increase of a summary content of galena and sphalerite in the system (30 to 90 %).

The authors chose the common thermobarometric conditions for modeling – T = +25 ºC and P = 1 atm. The rain water composition: N_3^-, N_2^- NH_4^+, $NH_4N_3^0$, HNO_2^0, $NH_4NO_3^0$, NH_4OH^0, $NH_4NO_2^0$, NH_3^0, $H_2CO_3^0$, HCO_3^-, CO_3^{2-}, $C_2O_4^{2-}$, CH_4^0, O_2^0, H_2^0, N_2^0, Ar^0, He^0, Kr^0, Ne^0, OH^-, H^+, H_2O^0, NO_3^-, HNO_3^0 (pH=5.66). The models were one-reservoir and opened to the atmosphere. The chemical composition of the atmosphere was calculated after R. Horne [4]. Ten kilograms of the atmosphere includes (moles): Ar – 3.209, C – 0.1036, N – 539.478, O – 144.8472.

In modeling of the hypergene processes in the CCM new and old tailing dumps of Dal'negorsk District the calculations embraced 19 independent and 380 dependent components that included 316 dissolved particles, 18 gases, and 47 minerals and solid solutions.

Results and discussion

Modeling was carried out for the sulfide oxidation in the contact with the enclosing rocks with the change of the galena and sphalerite percent content. All models were constructed on the averaged literature data [5, 6]. As the tailing composition is variable, the modeling was done with a summary content of galena and sphalerite of 30 to 90 %, and the remainder of them (to 100 %) included other sulfide minerals (Table 1). The ratio of the enclosing rock/sulfides was: 95:5, 90:10, 80:20, and 60:40.

The results of modeling of the tailing oxidation in the CMM tailing dump with different correlation of enclosing rocks/sulfides showed that with increasing content of galena and sphalerite in them the value of the acidity-alkalinity index of the solution (pH) is changed from 6.09 to 10.94 and oxidation-reduction potential – from 0.86 to 0.57 B.

The solutions of models for all ratios of enclosing rocks/sulfides contain the following elements (mg/l): Ca – 262.8 to 348.8, Na – 31.65-836.9, Ag – 209.9-1725, As – 10.9-2231, Sb – 11-92.7, Cu – 8.3-1968, Pb – 451.3-17510, S – 902.6-4783, Zn – 349.6-13550.

Through oxidation a portion of the primary minerals remains not-destructed in all models (%): albite – 0.04 to 6.26, andradite – 7.62 to 24.50, muscovite – 1.27 to 8.83, quartz – 0.46 to 7.84. Some minerals remain in the system only at the summary content of galena and sphalerite of 90 %. These are diopside (3.32 to 6.74 %), epidote (8.88 to 23.51 %), and potassic feldspar (3.29 %) (at 70 % and ratio of 60:40).

With increasing concentration of sulfides (galena and sphalerite) the quantity of hypergene minerals, being crystallized, decreases (Table 2): goethite – from 19.78 to 0.71 % and then it disappears from the system (at the summary content of galena and sphalerite of 50 % in the system the enclosing rock/sulfides ratio is 95:5 and at 90 % – 90:10 and 80:20), gypsum – from 51.11 to 0.10 in all models, montmorillonite – from 26.20 to 16.71 (for the system of 95:5). In other systems the montmorillonite amount increases and reaches its maximum of 26.27 (galena and sphalerite sum is 70 %), then its amount falls again to 4.76 (90 %, 60:40). The following minerals are crystallized only at the enclosing rocks/sulfides ratio of 60:40: plumbojarosite – 2.75 and 6.33 % (galena and sphalerite sum is 30 %), cerussite – 0.09 (70), and adamite – 0.07 (90). Ag and Sb minerals are not precipitated, and these elements remain in full in the modeled solutions.

The solution ion composition in the model variants with the summary content of galena and sphalerite of 30 to 50 % is similar and represented by: $Ag(CO_3)^-$, $Ag(CO_3)_2^{3-}$, $Ag(OH)_2^-$, Ag^+, $AgNO_3^0$, AgO^-, $AgOH^0$, $Al(OH)^{+2}$, Al^{3+}, AlO^+, AlO_2^-, AsO_4^{3-}, CO_2^0, CO_3^{2-}, $Ca(HCO_3)^+$, $CaHSiO_3^+$, Ca^{2+}, $CaCO_3^0$, $CaOH^+$, $CaSO_4^0$, $Cu(CO_3)_2^{2-}$, Cu^+, Cu^{2+}, $CuCO_3^0$, $CuHCO_3^+$, CuO^0, CuO_2^{2-}, $CuOH^+$, $CuSO_4^0$, Fe^{3+}, $Fe(OH)_2^+$, $Fe(OH)_3^0$, $Fe(OH)_4^-$, $FeSO_4^+$, $FeAsO_4^0$, FeO^+, FeO_2^-, $FeHAsO_4^+$, $FeH_2AsO_4^{2+}$, $H_2AsO_4^-$, $H_3AsO_4^0$, $HAlO_2^0$, $HAsO_4^{2-}$, HCO_3^-, $HCuO_2^-$, $HFeO_2^0$, HNO_2^0, HNO_3^0, $HPbO_2^-$, HSO_4^-, $HSiO_3^-$, $HZnO_2^-$, K^+, $KHSO_4^0$, KOH^0, KSO_4^-, $Mg(HCO_3)^+$, $MgHSiO_3^+$, Mg^{+2}, $MgCO_3^0$, N_2^0, NO_2^-, NO_3^-, Na^+, $NaAsO_4^{2-}$, $NaHSiO_3^0$, $NaOH^0$, $NaSO_4^-$, O_2^0, $Pb(OH)_2^0$, $Pb(CO_3)_2^{2-}$, $Pb(SO_4)_2^{2-}$, Pb^{2+}, $PbCO_3^0$, $PbHCO_3^+$, $PbNO_3^+$, PbO^0, $PbOH^+$, $PbSO_4^0$, SO_4^{2-}, SiO_2^0, $Zn(CO_3)_2^{2-}$, $Zn(SO_4)_2^{2-}$, Zn^{2+}, $ZnCO_3^0$, $ZnHCO_3^+$, ZnO^0, ZnO_2^{2-}, $ZnOH^+$, $ZnSO_4^0$, $HSbO_2^0$, $Sb(OH)_2^+$, $Sb(OH)_3^0$, SbO_2^-, OH^-, H^+, H_2O^0.

The ion composition of the solutions in the variants with more amount of sulfides (70 and 90 %) differs from the previous one in the absence of $Fe(OH)^{4-}$ and $FeAsO_4^0$ (at the enclosing rock/sulfides ratio of 95:5 and 90:10). In different models at 80:20 and 60:40 ratios the following ions are absent sometimes: $Ag(CO_3)_2^{3-}$, $HCuO_2^-$, $HPbO_2^-$, $HZnO_2^-$, $KHSO_4^0$, KOH^0, $MgHSiO_3^+$, $MgCO_3^0$, $Pb(CO_3)_2^{2-}$, $Pb(OH)_2^0$, $PbCO_3^0$, ZnO_2^{2-}, Cu^+, CuO_2^{2-}, Fe^{3+}, $FeH_2AsO_4^{2+}$, $FeSO_4^+$, $KHSO_4^0$, Al^{3+}, Fe^{3+}, $FeHAsO_4^+$, $FeH_2AsO_4^{2+}$, $FeOH^{2+}$, $Al(OH)^{2+}$, $Fe(OH)_2^+$, $FeAsO_4^0$, $FeSO_4^+$.

Mineralization of sulfide elements in the modeled solutions of the study variants is (g/l) from 2.85 to 17.3 (30 %), 3.56-3.61-23.3 (50 %), 4.07-28.4 (70 %); 4.82-34.7 (90 %). A total mineralization of the solutions is (g/l) 3.97-18.2 (30 %), 4.70-24.1 (50 %), 4.93-29.2 (70 %), 5.68-35.3 (90 %).

Conclusion

In conclusion it should be noted that the increasing summary content of galena and sphalerite in the system (from 30 to 90 %) makes it possible for plumbojarosite (only at 30 %) and adamite (only at 90 %) to be crystallized in the modeled systems. These minerals are precipitated at the enclosing rock/sulfides ratio equal to 60:40. In other cases Pb and Zn remain in solutions. Oxidation of Ag and Sb sulfides (argentite, acanthite and pyrargyrite) enriched the micropore solutions in these elements and increased their mineralization.

The results obtained testify to a significant evacuation of a wide range of elements of sulfide ores and enclosing rocks from the CCM tailing dumps into the surface waters polluting the hydrosphere with them. Mineralization of the solutions with the sulfide ore elements reaches 34.7 g/l, and a total mineralization is 35.3 g/l.

Acknowledgement

The authors are thankful to PhD Valeriy Bychinsky and PhD Alexey Tupitsin (A.P. Vinogradov Institute of Geochemistry SB RAS) for their help in the modeling.

Keywords: natural-mining industrial system, technogenic pollution, wastes, heavy metals, reclamation.

Abstract. The paper considers some ecological problems of the gold-mining enterprise in Amurskaya Oblast'. The investigations have revealed the technogenic pollution of the soil-grounds, air basin, and vegetation under the action of the processing wastes. High concentrations of heavy metals were found in the soils and vegetation in the zone of influence of the plant processing heavy concentrates at a distance of 100 and more meters. They are 2 to 90 times higher than the background values practically in all directions from the technogenic object. High TM concentrations were found also in the soils of building zone. Using the innovation approach we have elaborated the measures for decreasing the pollution negative effect on the habitat. We propose a new way of reclamation of the lands disturbed by the wastes of the mineral raw material processing with the use of the mixed bark-compost of the forest industry wastes.

Introduction

In Amurskaya Oblast' for almost 150 years they have been mining gold and have been developing the deposits of titanium-magnetite and other ores. The region possesses tremendous reserves of apatites, anorthosites, marbles, coal, and other useful minerals. Long exploitation of gold-placer deposits in Amurskaya Oblast' promoted the accumulation of great volumes of the wastes of ore processing resulted in technogene pollution of ecosphere, degradation and disappearance of the valuable species of plants and animals, intensive destruction of ecosystems, and sharp deterioration of the human habitat. Besides, the economical reorganization in Russia in 1990s didn't bring about the reconstruction of the mining enterprises. At present, the greatest threat is the emergency of many technogene systems, which year after year more and more actively undergo hypergenesis and technogenesis and contribute to the pollution of natural systems. All these cause the losses of the mining-industrial complex and threaten the people health and life. In Amurskaya Oblast', however, there so far is absent the scientifically justified system of evaluation and control of the ecological risk to provide the economical and ecological safety. In this connection the aim of our work was to reveal some ecological problems of the wastes of the gold-placer deposit processing to provide their ecological safety. So our tasks were as follows: 1. To analyze and generalize the literature data on this problem; 2. To investigate the wastes as a source of negative action on soils and vegetation and evaluate their influence on the environment state; 3. To elaborate the innovation proposals for decreasing the effect of the wastes of the mineral raw material processing on the natural systems and population of the mining settlement.

Objects and Methods of Research

The objects of investigation were the natural-mining-industrial systems. We used, as the methodological basis, the Academician V.I. Vernadsky's teaching [1] on biosphere and noosphere and the principal theses stated by B.P. Kolesnikov and N.V. Motorina in "Program and methods of study of technogene biogeocoenoses" [2].

We took the soil-ground samples according to GOST 17.4.3.01-83 and GOST 17.4.4.02-84 and the vegetation samples according to GOST 27262-87. We used, as the background index, the area, remote from the main sources of pollution, that is located at 10 km from the concentrating plant. In this case we took account of the "wind rose". Our investigations covered the area more than 12 km^2 in size. The physical-chemical, chemical, and biological methods (test-systems "Pollen sterility" and "Growth test") were used.

Results and discussion

Analysis, generalization, and systematization of the literature data and materials of the patent search testify that through the processing of mineral raw materials the environment is subjected to the intensive technogene effect [3-7 others], one of the main negative sources being the storage of the concentration wastes on the territory of the mine settlement. For their placement the productive lands, including those of the forest stock, are used. The wastes, stored as tailing dumps, contribute to the pollution of the air and water basins resulted in the deterioration of the hydrological regime of the region. Concentrations of heavy metals in the air are 37 to 43 times higher than the background characteristics and in the surface waters – 6 to 19 times. In this case the ecological value of mountain landscapes decreases, the species diversity of vegetation and animal world is reduced, the soil cover is destroyed, the erosion processes become active, and so on [3-7]. Therefore, the evaluation of the consequences of the technogene pollution of the environment by the wastes of the processing of mineral raw materials and elaboration of the nature-protection measures in the study region is an urgent problem for providing their ecological safety.

Considering the wastes as a potential source of pollution we established that their composition is represented by diverse minerals: ilmenite, magnetite, wolframite, hematite, garnet, arsenopyrite, galena, cassiterite, epidote, zircon, pyroxene, and cinnabar. The wastes are characterized by a high content of heavy metals (HM): Cu, Pb, Zn, Sn, Hg, Mn, and others. Heavy fractions are rich in not only zircon, but ilmenite also. High concentrations of Pb, Cu, and Zn were established in the northeast direction. With distance (700 m) from the concentrating plant (CP) the content of both bulk and mobile forms of HM decreases. Heavy metals migrate from the wastes not only into the soils, but into the vegetation also. The quantity of HM in the studied mobile forms in the technogene soils in the zone of the CP influence significantly exceeds the background values (2 to 92 and more times) practically in all directions from its center.

Our investigations showed that the characteristic feature of the technogene pollution of soils is the accumulation of elements in the near-surface horizon. This is governed by precipitation (with wind carrying) of dust particles onto the soil surface layer and bonding of HM with organic matters and finely dispersed particles. As a rule, within the miners' settlement the main danger for the population health is the increasing concentration of heavy metals in the air and in the upper layer of the technogene soil.

High concentrations of heavy metals (Cu, Pb, Zn, As, etc.) exceeding the background values (1.5 to 14 times) and MPC (3 to 11 times) were found also in the vegetation, in the building zone at a distance of 1.5 km from the plant processing heavy concentrates. Correlation between the content of the mobile TM in the technogene soils and cytogenetic changes in the cells of the plant-bioindicators (the "Pollen Sterility" test-system) has been revealed. A direct dependence of the pollen sterility on the degree of the technogenic pollution has been recognized.

Biological methods (test-systems, study of microflora) allowed us to estimate the ecological situation in the district as critical. When investigating the agricultural production, we found that it accumulates big amounts of heavy metals, excess being 3 to 10 LPC.

The data obtained allowed us to divide the polluted mining-industrial territory into three zones:

1) zone of critical pollution where the TM contents are 3 to 56 and more times higher than a permissible norm (territory of the concentrating plant);

2) zone of mean pollution – amount of the TM mobile forms in soils is significant, exceeding the MPC for 2 to 4 times;

3) zone of satisfactory pollution – amount of the TM mobile forms in soils don't exceed the MPC: Zn -9-13 mg/kg, Pb – 3-4 mg/kg; Cd – 0.2 mg/kg.

Imperfection of technologies used in the mining industry is one of the main factors of the negative effect on the ecosystems.

Undoubtedly, the ecological problems in the miners' settlement are caused by the technology of mining and concentrating, storage, and deposition of the wastes, as well as by the mineral composition of the processed ores and wall rocks. As a result, the process of the risk control becomes complicated, because a constantly increasing number of its parameters and factors must be taken into account. The most important group of the fundamental factors includes: technological (technogene) and organization factors and the state of the economical and social-economical situation [6]. Their action on the biosphere components should be considered in complex with regard to their mutual influence and hierarchical relations. The role of the natural factors, such as specific features of climate, landscape, relief, and others, in these processes is great. In this connection, of great importance is the estimation of the ecological tension of the study district territory. The calculations showed that the complex index of the ecological tension, which reflects the role of the geomorphogenetic, cryogenic, soil-genetic, and climatic factors in their interrelation, turned to be critical of 2300 to 7000 points, testifying the necessity of a strict regulation of the nature management in Amurskaya Oblast'.

The technogene pollution of the ecosphere in Amurskaya Oblast' contributes to the ecology-caused diseases of respiration, digestive, nerve, and other organs. We have calculated the economic damage to the population health and found that children and working people and pensioners run the danger of this action to the greatest degree.

The highest summary index of danger (HI), equal to 71, has been recognized for a group of the matters affecting the man respiration organs, and namely the suspended matters, copper, chrome, sulfur dioxide, and others.

The technogene pollution of the soil-vegetative cover makes it urgent to take the measures for decreasing the concentrations of the polluting matters and withdrawal of them beyond the soil profile, as well as the preservation and recreation of the vegetative cover to prevent the wind and water erosion and technogene pollution by means of phytoreclamation. The innovation measures are proposed for improving the habitat in the miners' settlement of Amurskaya Oblast'. We have elaborated the method of reclamation of the lands disturbed by the wastes of the mining works with the use of the mixed bark-compost of the forest-industry wastes (Figure 1), and its novelty is confirmed by the Patent of the Russian Federation (of July 10, 2013).

The original material we have obtained may be used in the study of the dynamics of development of the regional nature-mining-technical systems.

Conclusions

Our investigations made it possible to reveal some ecological problems (technogene pollution of soil-grounds, air and water basins, vegetation) arisen through the development of the mineral raw materials in Amurskaya Oblast' and to elaborate the measures for decreasing the negative action of the processing wastes on the habitat with innovation approach. We propose the way of reclamation of the lands, disturbed by the wastes of the mineral raw material processing, with the use of the mixed bark-compost of the forest-industry wastes.

Keywords: Stone Processing; Wastewater Treatment; Sedimentation Tank

Abstract. In the process of stone cutting and polishing, a large amount of high turbidity water is produced, which causes the waste of water resources and the pollution of the environment. The traditional treatment process is optimized, taking problems occurred in sewage treatment process by small and medium-sized enterprises and the existing technology and method into consideration. According to the production process of stone, the amount of waste water generated every day is calculated, which provides a theoretical basis for the sedimentation tank optimization and design. The necessity of stone wastewater reuse is illustrated.

Introduction

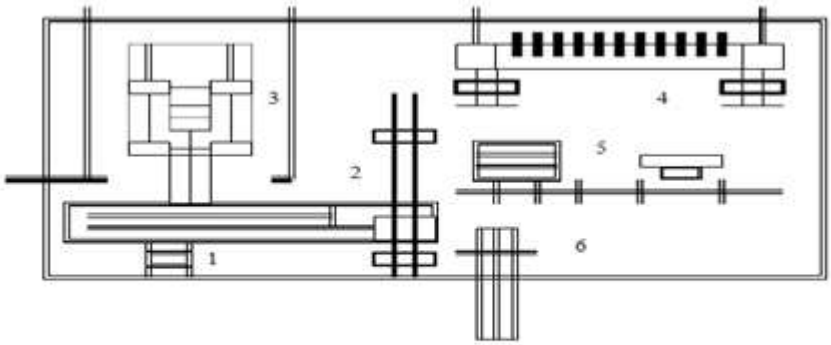
With the development and expansion of stone processing enterprises, a large amount of water is used in stone processing. The powder from stone is mixed with water, forming a large quantity of stone wastewater. The deterioration of water quality caused by the discharge of industrial sewage is an important cause of water pollution [1]. At present, the cleaner production index has been enacted in the stone industry. Cleaner production is not only to achieve low pollution in order to guide the reasonable arrangement of process, but also to realize optimization of manufacture process. Social benefits should be achieved without affecting the economic efficiency of stone enterprises, creating a win-win situation for both the producers and the public interest [2]. Stone wastewater is recycled, which can save a lot of water effectively and reduce environmental pollution. Recycled water can be used for industrial cooling water and process water, promoting the wide extension of cleaner production.

An Overview of Stone Wastewater Treatment

In the process of cutting and grinding stone slabs, a lot of heat will be produced, which will affect service life of diamond tool. As a result, water is often used to cool the diamond tool and remove grinding powder and clean the surface of stone slabs, producing a large amount of sewage. The ingredients of stone materials are very complex, and the main component of sewage caused by them is a mixture of water, abrasive dust, slag grinding grain, marble and granite debris.

Technological Process of Stone Processing. Stone processing directly affect the sewage emissions. In processing stone slab, an amount of sewage is produced and stone procedure mainly involve block cutting, grinding, polishing, cutting, splitting, inspection, and packing. The production line diagram about stone procedure is shown in Fig.1.

When sawing block, the block stone is put on the ferry car by crane, then block is carried to block car, and block is sawed into gross slab with gang saw machine. Gross slabs are sent to the continuous grinding and polishing line for grinding and polishing by rail. When slab is polished, according to the requirements of the project, the polished slab is cut into the slabs with different sizes by bridge cutting machine.



1 – Block car; 2 - Ferry car; 3 – Gang saw; 4 – Automatic grinding-polishing machine; 5 - Bridge cutting machine; 6 – Crane

Fig.1. Diagram of stone slabs production line

The Amount of Sewage Produced in Stone Processing. Equipment and operation parameters are analyzed and calculated, taking sewage treatment in processing stone slabs of middle and small-sized enterprises into consideration. Block stone with size $3250mm \times 2050mm \times 2000mm$ （$L \times B \times H$） is taken as an example. When annual working days d is300, daily working time t is 8 hours, the required equipment number is 2 block machine and a polishing line and 2 bridge cutting machine. According to the whole production process the daily water consumption amount is calculated as the following formula.

$$Q_w = (2v_s + v_m + 2v_c)t \tag{1}$$

In the formula: v_s is water consumption of block machine, which is 800L/h; v_m is water consumption of automatic grinding-polishing machine, which is 200L/min; v_c is water consumption of bridge cutting machine, which is $4m^3/h$.

Daily produced sludge is calculated as the following formula.

$$Q_m = Q_{sm} + Q_{mm} + Q_{cm} = \frac{2V_s tBHb_1 n}{L} + \frac{V_b tHb_2}{B} + 2V_c tb_3 d \tag{2}$$

In the formula: Q_{sm} is sludge produced by block machine. b_1 is sawing blade width of block machine, which is 2mm; the number of saw blade n is 8; the feed speed V_s is value range of 0 ~ 55cm/h; the saw blade spacing d is general scope for 1 ~ 2cm. Q_s is the amount of sludge generated by automatic grinding-polishing machine. According to automatic grinding-polishing machine amount grinded b_2 is 3mm; V_b is the speed of conveyor belt, which is 0 ~ 2m/min. Q_{cm} is sludge produced by the bridge cutting machine. According to the bridge cutting machine blade sawing width b_3 is 2.5mm, cutting speed V_c is 0 ~ 15m/min. On the basis of the above formula, Q_m is gotten.

Thereby the total amount of sewage generated every day is calculated as the following formula.

$$Q = Q_w + Q_m \tag{3}$$

Technology Development of Sewage Treatment of Stone

The Transformation of Traditional Processing Technology. Usually the traditional wastewater treatment technology depends on a few simple sedimentation tanks. According to the analysis of sewage treatment process, deposition velocity in sedimentation tank is slower, the purification ability is limited and a larger area of the sewage treatment sedimentation tank is required. The upper overflow water is difficult to reach the recycle standard with this method [3]. For the smaller stone enterprises, sludge is cleaned regularly at the bottom of sedimentation tank. If mud is cleaned production will be stopped. As a result, not only a lot of production time is cost, but also the enterprise's economic benefit is influenced [4].

To reform the traditional sewage treatment technology, a new type of sewage treatment technology is put forward, whose process diagram is shown in Fig.2.

Sewage from stone processing workshop flows into the sewage tank. Wastewater is sent to the primary sedimentation tank by liquid submerged sewage pump. At the same time, the suitable flocculant is put into the water to make powder particles accelerate coagulation sink and eventually the solid-liquid separation is finished. At the bottom of primary sedimentation tank the sludge is intermittently discharged into the mud pit. Because the sewage is sent to the primary sedimentation tank, the upper water is forced to overflow to the secondary sedimentation tank. Appropriate flocculant is also added to the secondary sedimentation tank. The upper clear water flows into the reservoir. The sludge is sent to the dehydration equipment for separating mud and water. After that, water which flows into the tank can be recycled, the filter mud cake is transported to another application.

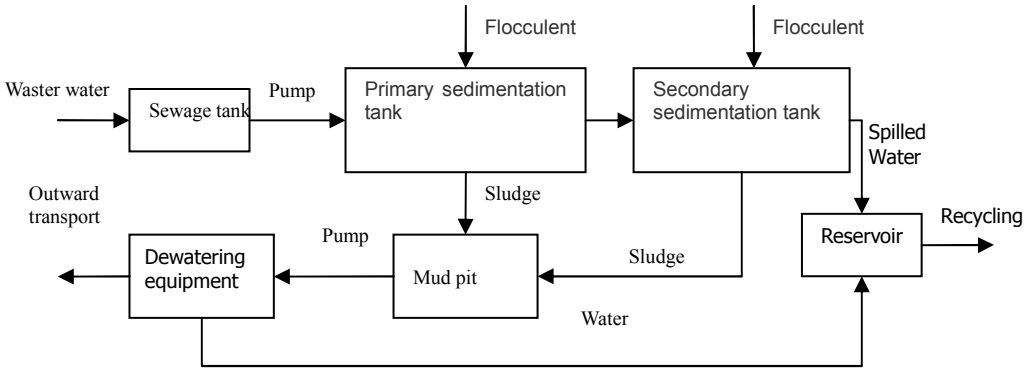


Fig.2. Flow diagram of sewage treatment process

Design of Sedimentation Tank. In the stone processing at present, sedimentation tank is commonly used in the wastewater treatment. Therefore there are four main types which involved horizontal flow, vertical flow, radial flow and inclined plate [5]. In the process of small and medium-sized enterprises construction, the economic cost and its production capacity should be taken into account. Usually only a few simple horizontal sedimentation tank is selected, but more land is occupied when using this method and the purification ability is limited. The horizontal sedimentation tank and rotating mechanism is adopted on the basis of the equipment, as shown in Fig.3. Separation effect and processing capacity of tank are improved further, the blade of inclined plate can increase the subsidence area and improve the flow state of wastewater. Compared with the general sedimentation tank, surface load and the processing ability of the sedimentation tank are largely improved.

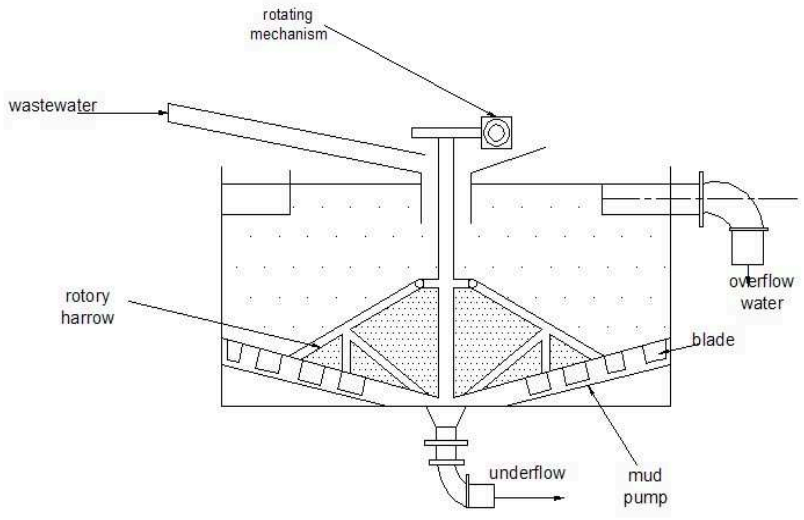

Fig.3.The new sewage sedimentation tank

In the sewage the solid particles settlement way is gravity sedimentation. Center in sedimentation tank rotary harrow revolve slowly, and the speed is $0.1 \sim 1r/\min$. The speed of primary sedimentation tank and the secondary sedimentation tank is different. Generally the speed of the secondary sedimentation tank is slightly quicker.

Conclusion

According to the production condition of small and medium-sized enterprises and the standards of wastewater treatment, the parameters of the process are designed, taking the processing of stone slabs as an example. The emissions of sewage stone processing enterprises have been calculated, taking stone processing into account. Considering the existing sewage treatment technology and method, the traditional processing technology has been transformed into interaction form which functions by the primary sedimentation tank and the secondary sedimentation tank, achieving the preliminary planning of the new sewage treatment process. In this design, rotating mechanism equipment has been adopted on the basis of horizontal sedimentation tank, improving the separation effect and processing capacity of tank.

Keywords: Accumulation; *Vetiveria Zizanioides*; Earthworm; Cr Contaminated Soil

Abstract. The trial of the earthworm-assisted phytoremediation of Cr in contaminated yellow soil was made to study the performance of earthworm in Cr accumulation of Vetiver Grass (*vetiveria Zizanioides* VG). Two groups were designed, adding earth worm(marked EM) and not adding earth worm(marked NEW).The result showed *Vetiveria Zizanioides* can absorb great amounts of chromium in soil, the decline rate of Cr was up to 75% and 78% respectively in EM and NEM at 60th day. Both root and shoot can accumulate Cr from soil. As the concentration of Cr gradually increased within 0-80mg/kg，the accumulation activity of two groups presented first increase and then decrease and reached maximum 644.31mg/kg, 943.14 mg/kg in root when the Cr concentration was 80 mg/kg. It began to decrease when the Cr concentration was above 120mg/kg.*Vetiveria Zizanioides*'s accumulation ability differs in root and shoot. It presented root>shoot. With a comparative analysis, EM has higher accumulation and resistance of Cr at any designed treatments. In the analysis of relation between plants and soils, it was found that there was significant correlation in Cr contents between plants and soils ($P<0.05$). Furthermore, there was extremely significant correlation ($P<0.01$) between root and shoot in EM. There was a high retention rate of *Vetiveria Zizanioides* root to Cr. Retention rate of any treatments were all greater than 83% except 120mg/kg in EM. Plants kept much higher concentrations of Cr in roots than in their respective shoots. The biggest value was up to 96.23%. There was no obvious difference between EM and NEM in retention rate. Earthworm-assisted phytoremediation has high efficiency in Cr contaminated soil. It's an idea method to Cr contaminated soil.

Introduction

Soil contamination, a very important environmental problem, has attracted considerable public attention in recent years. Heavy metal contamination in soils is one of the world's major environmental problems. it caused great risks to human health as well as to ecosystems[1]. Toxic heavy metals can cause different health problems depending on the heavy metal concerned, its concentration and oxidation state, etc[2][3].

Chromium (Cr) is a transition element naturally occurring materials. It may exist in a series of oxidation states of which the major stable forms are the trivalent (Cr^{3+}) and the hexavalent (Cr^{6+}) [4]. In the last few years the number of Cr contaminated sites has increased and hence Cr pollution has attained considerable attention being regarded as a major area of concern worldwide.

Phytoextraction is an environmentally sound and cost-effective technology for cleaning up soils contaminated with toxic metals. This technique has repeatedly been suggested as a novel clean-up technology. It has the potential to provide cost effective, renewable alternatives to previously used remediation techniques. Vetiver grass (*Vetiveria Zizanioides*,VG) was originally produced in India and was successfully introduced to China in the 1950s. It is an ideal plant for moisture and soil conservation[5][6].

Earthworms construct a major component in soil and play an important role in soil ecosystems. They contribute to organic matter incorporation and decomposition, excavation of burrows. They play an important role in chemical element transformation[7].

But in the previous studies about animals-plants combined remediation, there's few research focused on accumulation properties of chromium in *Vetiveria Zizanioides* induced by earthworm. The goal of this study is to understand the performance of the earthworm-assisted phytoremediation of Cr contaminated yellow soil. It has an important practical significance to improve the animal-assisted phytoremediation research as well as the development of *Vetiveria Zizanioides* ecological engineering.

Materials and Methods

Soil Preparation

Uncontaminated yellow soil was collected from 0 to 20cm depth from botany garden Sichuan, China. The soil was air-dried, crushed to pass through a 2mm diameter sieve, and mixed thoroughly. 7kg soil samples were placed in plastic pots with 35cm diameter and 40cm height. There were six groups of processing and each processing set three repetitions. Chromic acid dipotassium(K_2CrO_4) was added. The final concentration of soil were 0mg/kg,10mg/kg, 20mg/kg, 40mg/kg, 80mg/kg, 120mg/kg respectively. In each processing, 15 earthworms (*Eisenia Foelide*) were taken into each plastic pot apart from control group.

Plant Materials

Vetiveria Zizanioides were obtained from Sichuan seeding company. Simple root baptism treatment was conducted before planting. 5 strains were evenly planted in each plastic pot. Keep the house temperature at 25 to 29 degrees Celsius after planting in greenhouse, watered in time.

Chromium Concentrations in Soil

Soil samples were analyzed after they had been ground in a stainless steel mill to pass through a 2mm sieve for analysis of following parameters. Soil samples were digested with HF–HNO3–HClO4 using a microwave. Concentrations of heavy metals were determined using an atomic absorption spectrophotometer(AAS- TAS-900).

Metal Concentrations in Plants

After 60 days, ground part (shoot) and underground part (root) were separately harvest. They were washed by deionized water and dried in dryer to constant weight, weighing. Both ground samples and underground samples (0.25 g) were digested in concentrated HNO3–H2O2 using a digestion block. The digested samples were brought to a constant volume (25ml) with deionized water, and the digests were analyzed for Cr using AAS.

Statistical Analysis

The data were analyzed using one-way analysis of variance (ANOVA) and Duncans Multiple Range Test in the SPSS software to compare the means of heavy metal concentrations in different treatment.

Results and Discussion

Contents of Cr in soil during experiment period

The content of Cr in soil during experiment period are presented in Fig.1 and Fig.2 The concentration of Cr in soil gradually decreased In NEW and EW groups from 10th to 60th day. In the treatment of 10mg/kg, the concentration decreased to 2.4 mg/kg, while in treatment of 120mg/kg, the concentration decreased to 54.2 mg/kg. The speed of Cr decline was slow at the concentration of 10 treatment of 10mg/kg, the concentration decreased to 2.4 mg/kg, and became faster at the concentration of 20-80t treatment of 10mg/kg, the concentration decreased to 2.4 mg/kg then dropped slightly at the concentration of 120 treatment of 10mg/kg, the concentration decreased to 2.4 mg/kg. Compared with NNW, NW has the same trend in decline of soil Cr. but at the presence of earthworm, the speed of Cr decline in soil is faster than any treatments in NEW. It indicates that earthworm play

an important role in declination of soil Cr concentration. The accumulation activity of two groups presented first increase and then decrease, and reached maximum 644.31 mg/kg, 943.14 mg/kg. Devliegher[8] explains earthworm improve plant nutrients in the soil such as Ca, Fe, Mn and the effectiveness of the metal elements such as Cr, Co from intestinal digestion and nutrient enrichment of two aspects. Deng Jifu [9] heavy metal contents in earthworms in industrial area were studied. It was found that the accumulation ability is very strong, and the enrichment of content is positively related to the content of soil.

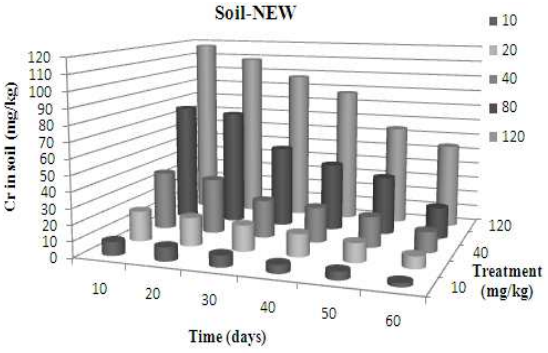

Fig.1 Changes of Cr content during the experiment period in NEW soil

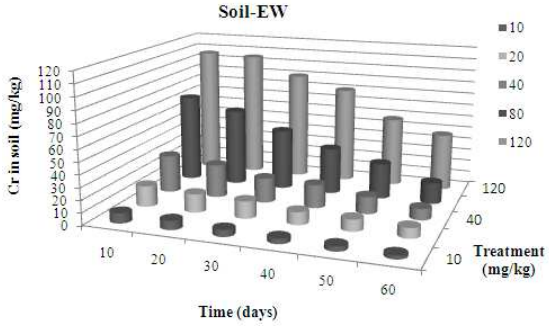

Fig.2 Changes of Cr content during the experiment period in EW soil

The degradation rate of chromium in soil is presented in Table1. In the NEW group and EW group, the degradation rate increase as time goes on. The degradation rate was 19% in the 30th day, the degradation rate was 55% at 60th day at treatment of 120mg/kg. On the contrary, in the EW group, the degradation rate in 25% 25% 30 days and 60 days, were greater than the NEW group. This suggests that earthworms play an important role in degradation of heavy metals in the soil. Earthworms play roles in many ways. Such as making holes in feeding, excreting metabolic product in the process of life activity and changing chemical behavior of heavy metals in soil, which have an impact on uptake of heavy metal direct or indirect way.

Table.1 Decline rate of soil Cr in different treatments

Cr (mg/kg)	NEW		EW	
	Decline rate within 30 days	Decline rate within 60 days	Decline rate within 30 days	Decline rate within 60 days
10	27%	76%	46%	72%
20	18%	62%	30%	59%
40	40%	67%	49%	77%
80	35%	75%	37%	78%
120	19%	55%	25%	61%
AVG	28%	67%	37%	69%

Concentration of Cr in shoot and root

The concentration of Cr in shoot and root is presented in Fig.3 and Fig.4. Different parts of the plant to heavy metal Cr accumulation to a certain extent, with increasing concentration of Cr in soil, every part of VG on the uptake of Cr is raised. The root of VG has strong accumulation ability to the heavy metal ions. It was also proved in this study. The concentration of Cr in root was up to 953.03mg/kg in treatment of 120mg/kg in NEM. While in EM, the content of Cr in all the treatment was higher than NEM except treatment of 120mg/kg. It was unexpected drop at treatment of 120mg/kg in EW, it's unusual. The reason is need to do further study.

Accumulation of heavy metals in plants in vivo distribution is related to the activity of the various metal itself, also with all kinds of plant adaptation to heavy metal tolerance mechanism. In plant adaptation mechanisms of metal, or by the root structure or certain physiological features limit the harmful heavy metal ions from the root to the aboveground part transfer, maintain the ground part of low heavy metal content, make the aerial parts of plants have higher physiological activity, Or take the

harmful heavy metal accumulation into easy to fall off part, through the parts fall off, from harmful heavy metals plant. [10][11][12]

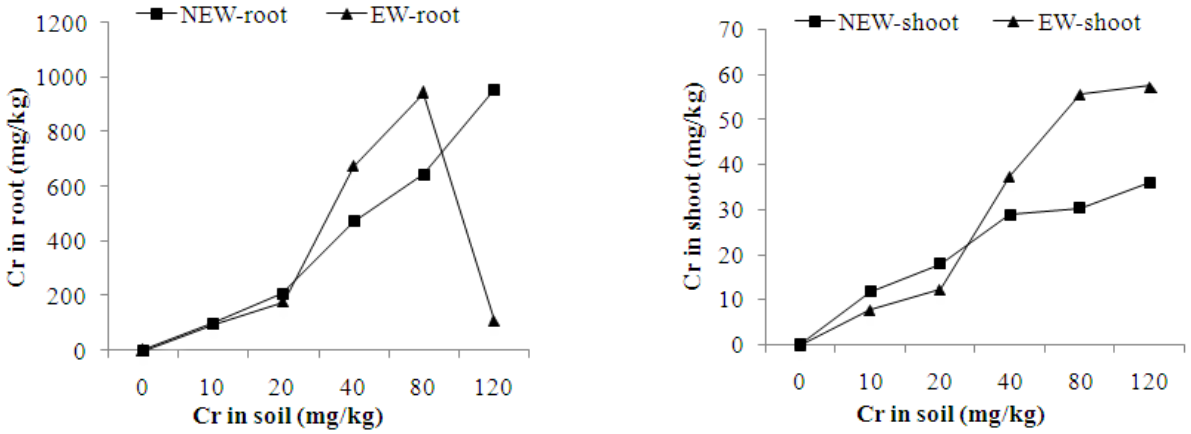

Fig.3 Fig.4 The concentration of Cr in root and shoot

VG can accumulate large amount of Cr in shoot and root. The roots can absorb more Cr than shoot. Cr content of VG from different parts of the body is characterized by underground parts > the ground, it is a common phenomenon in the plant study before. It indicates that Cr in the root rarely transport to the ground. Comparison between adding and without adding earthworm into soil for control, it was found earthworm can improve the uptake of Cr at low concentration.

Paul Truongu [13] showed that the tolerance ability of ordinary plant shoot to Cr, Ni, respectively 0.02 -0.20 mg/kg and 10-30 mg/kg. In this study the contents are significantly higher than previous studies, may caused by soil nutrient and type or some other reason, which needs further research.

Correlation Coefficient between Cr of VG and Soil

Correlation coefficient between Cr of VG and soil is presented in Table2. The results showed that Cr in shoot and root and soil Cr have good correlation. In the NEW group, the correlation of shoot and soil is significant ($P < 0.05$). In the EW group, there is significant correlation between soil and root and shoot ($P < 0.01$)

Table 2 Correlation coefficient between Cr of VG and soil

	NEW		EW	
Items	root	shoot	root	shoot
Pearson Correlation	0.987**	0.883*	0.970**	0.942**
Sig. (2-tailed)	0	0.02	0.006	0.005
N	6	6	5	6

**. Correlation is significant at the 0.01 level (2-tailed).

*. Correlation is significant at the 0.05 level (2-tailed).

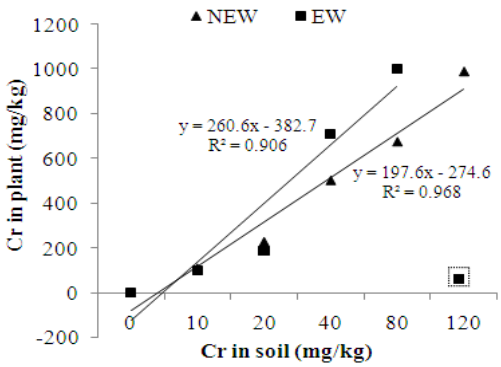

Fig.5 Linear relation between Cr content in VG plant and in soil

It was indicated from Fig.5 Increases with the concentration of Cr in soil, the concentration of VG is on the rise, It showed a linear correlation between Cr concentrations in soil and plant, correlation coefficient, r = 0.9065 and r = 0.9608. In the NEW and the EM group, the regression equation of Y=260.6x-382.7 and Y=197.6x-274.6

Accumulation Factor

Accumulation factor is presented in Table.3 Accumulation factor reflects the absorbing ability of root to heavy metal it Can be seen from table 3.VG'S s roots have very strong accumulation ability. In various concentrations, VG has the ability of chromium accumulation, which were characterized by the root is greater than the shoot. The high value in root is 16.83, in shoot in 0.12. Among which, in the NEW the largest accumulation factor is 11.83.A minimum of 7.94. In the EW group, root accumulation coefficient is 16.83, the highest value in shoot up to 0.93.

Root changes over concentration of heavy metal enrichment coefficient, when the soil heavy metal content exceeds a certain value, the accumulation factor of root is negative correlation with soil heavy metal content, this is mainly because of heavy metals to cell damage reduces the absorption of root. Root accumulation factor of Cr is quite high. Accumulation factor of shoot is very low. The result is same with previous studies. [12][14]

Table 3 Accumulation factor of VG-root and shoot to Cr

Cr (mg/kg)	NEW		EW	
	root	shoot	root	shoot
10	9.73	0.54	9.31	0.76
20	10.46	0.37	8.72	0.61
40	11.83	0.23	16.83	0.93
80	8.05	0.13	11.79	0.69
120	7.94	0.12	0.88	0.48
AVG	9.60	0.28	9.51	0.69

Table 4 Cr retention rate in VG-root

Cr (mg/kg)	NEW	EW
10	87.91%	91.84%
20	91.46%	93.00%
40	93.93%	94.47%
80	95.30%	94.12%
120	96.23%	45.62%
AVG	92.97%	83.81%

Retention Rate

Cr retention rate is presented in Table.4 Cr retention rate is all above 83% in both NEW and EW groups except treatment of 120mg/kg.Cr retention rate is Up to 96.23% in NEW group. The retention rate is up to 94.47% in EW.

Comparing the retention rates of Cr and other heavy metal to previous study [15], it can be concluded that Cr is different from other heavy metal. Content of Cr in root is much more than in shoot. And almost all Cr stranded in the root, less to stem leaves .Root retention rate of heavy metals and the soil heavy metal content and whether to join the earthworm there was no significant correlation, that is to say, for a certain heavy metals, as the change of concentration, retention is almost a constant. This conclusion is consistent to previous research[16].

Conclusion

This study shows *Vetiveria Zizanioides* has very high tolerance to Cr and could accumulate Cr in roots and shoots. Degradation rate increased after adding the earthworm. As the concentration increased, degradation rate also has a tendency to reduce. But compared to NEW, EW group is only slightly decreased at the condition of high concentration. This suggests that earthworms play an important role in soil pollution remediation.

Under the condition of earthworms significantly enhanced the uptake capacity of each part. It is only slightly decreased at the condition of high concentration. Chromium content in the soil and plant roots, shoots are extremely significant correlation in EM ($P<0.01$). The accumulation capacity of VG in shoot was significantly higher than previous study. This may be related to type of soil and *Vetiveria Zizanioides* or other reasons. It needs further research.

In terms of accumulation characteristics, *Vetiveria Zizanioides has* similar properties to other heavy metal uptake, root > shoot. But unlike other heavy metal, chromium transfer coefficient is low, high retention rate in NEW and EW, at 92.97% and 83.81% respectively. Retention rate has nothing to do with the content of chromium concentration in the soil.

Earthworm-assisted phytoremediation is an idea method to Cr contaminated soil. *Vetiveria Zizanioides* has the properties of strong resistance ability high accumulation and high biomass, etc. It can be concluded from this study .Combination of earthworm and accumulation plants (*Vetiveria Zizanioides*) have obvious effect in soil remediation of heavy metal contamination. Therefore, comprehensive bioremediation technology in the future will be the main research direction of heavy metal contaminated soil remediation.

Keywords: Cr(VI); Ni; combined exposure; Cyperus alternifolius

Abstract. In order to investigate the ability of Cyperus alternifolius in restoring water with combined heavy metal pollution, water cultured experiment was utilized to study the accumulation and the tolerance mechanism of Cr(VI) and Ni in Cyperus alternifolius under the combined Cr(VI) and Ni exposure. The results showed that under Cr(VI) and Ni combined exposure, low concentration Ni improved the enrichment and translocation ability of Cyperus alternifolius for chromium, while high concentration Ni had opposite effects. The enrichment ability of Cyperus alternifolius for chromium was stronger than for Ni. With the increasing of Cr(VI) and Ni concentrations, fresh weight increment and chlorophyll content showed upward trend firstly and then downward, MDA content showed a rising trend and increased significantly. When Ni concentration was between 0~1mg·L^{-1}, SOD and CAT activities of Cyperus alternifolius increased first and then decreased with increasing Cr(VI) concentration, and root activity increased continuously. When Ni concentration was between 10~20 mg·L^{-1}, Cr(VI) and Ni interaction decreased SOD,CAT and root activity significantly. These results show that Cyperus alternifolius had tolerance and enrichment ability to Cr(VI) and Ni, and Cyperus alternifolius can be used to restore Cr(VI) polluted water and Cr(VI)-Ni combined polluted water under low Ni concentrations.

Introduction

With the rapid development of industry, Cr and Ni flow into the water in varieties ways, which has caused a serious impact to the aquatic environment and has a serious threat to animal and human health. Obviously, it has become a major global concern environmental problem. Cr and Ni are the trace elements closely related to human health and life, however, it's toxic to the plants and animals clearly on the excess. Phytoremediation is a green remediation technology for contaminated soil. Because of its easy operation, wide adaptability and no secondary pollution, it has become a hot technology for heavy metal pollution restoration. Currently, scholars put emphasis on the remediation of single heavy metal pollution, but actually situations are that a variety of heavy metals coexists[1]. Therefore, the study of the mechanism of heavy metals in plants under the combined pollution has a double meaning in theory and practice for the remediation of heavy metals compound pollution.

Cyperus alternifolius is a fast-growing, adaptable cyperaceae perennial evergreen herbaceous plants, and has a good ability to accumulate Single Cr(VI) and Ni[2]. To explore the patience of Cyperus alternifolius, as well as the feasibility of the restoration of heavy metals compound pollution, experiments were utilized to study the accumulation and the tolerance mechanism of Cr(VI) and Ni in Cyperus alternifolius under combined Cr(VI) and Ni exposure, designing to provide a theoretical basis about the restoration of Cr(VI) and Ni complex contaminated water by Cyperus alternifolius.

Materials and Methods

Plant material

Cyperus alternifolius seedlings were selected as tested plants.

Experimental Design

Experimental design with two factors was adopted and the tested plants were cultured in Hoagland nutrient solution adding different Cr(VI) and Ni concentration. Cr(VI) and Ni in nutrient solution were added with the form of K_2CrO_4, Ni $(NO_3)_2$ respectively. Each experiment was repeated three times and the specific designs were shown in Table 1.

Table 1 Experimental design ($mg \cdot L^{-1}$)

Cr(VI)	Ni		
	1	10	20
1	treatment 1	treatment 4	treatment 7
10	treatment 2	treatment 5	treatment 8
20	treatment 3	treatment 6	treatment 9

Measurement methods

Cr(VI) and Ni: ICP (ICAP6000, Thermo Scientific). The biomass: drying weighing method[3]. Chlorophyll content: using 80% acetone extraction, spectrophotometry. SOD activity: NBT photoche- mical reduction method[3]. CAT activity: potassium permanganate titration method [3]. MDA content: thiobarbituric method[3]. Root activity: TTC method.

Results and Discussion

Fresh weight increment

As could be seen from Figure 1, Cr(VI) and Ni combined pollution had a significant impact on fresh weight increment of Cyperus alternifolius. When Ni concentration was fixed, fresh weight increment decreased with the increasing of Cr(VI) concentration. When Cr(VI) concentration was fixed, fresh weight increment showed a similar tendency. At combined pollution of Cr(VI)(1 $mg \cdot L^{-1}$) and Ni(1$mg \cdot L^{-1}$),fresh weight increment reached a maximum of 3.14 (g/plant) , and was 92.64% significantly higher than that of CK. When the dealing concentration reached up to 20 $mg \cdot L^{-1}$, fresh weight increment was lower than that of CK. This indicated that at low Cr(VI) and Ni concentrations, their interaction played a catalytic role on the growth of Cyperus alternifolius, while at high concentrations, they restrained the growth of Cyperus alternifolius and made the biomass reduce. This result was consistent with Wu's study about the effect of heavy metal Cd of Aegiceras corniculata seedlings[4].

Cr (Ⅵ) and Ni content

Studying the repair of heavy metal by plant, not only weights plants patience of heavy metals and the accumulation ability, also should consider its transfer ability of heavy metals from roots to shoots. Figure 2 indicated that when at the same Ni concentrations, the total chromium content in the upper and root of Cyperus alternifolius gradually increased with the increasing of Cr (VI) concentrations, while the cumulative amount of nickel was gradually decreasing. The upper total chromium content reached up to 1729.67 $mg \cdot kg^{-1}$ at treatment 6. Views were preliminary held that Cr (VI) had inhibitory effect on cumulative Ni of Cyperus alternifolius. When at the same Cr (VI) concentrations, the total chromium content in the upper of Cyperus alternifolius showed upward trend firstly and then downward with the increase of Ni concentrations, while the cumulative amount of Ni was gradually increasing. The upper Ni content reached a maximum of 1383.06 $mg \cdot kg^{-1}$ at treatment 7. It indicated that the enrichment ability of the Cr was greater than the Ni.

When Cr (VI) concentration was fixed, the ratio of the total chromium enrichment content in shoots and roots rose at first and went down latter with the increasing of Ni. Showing that low concentration Ni improved the enrichment and translocation ability of Cyperus alternifolius for chromium, while high concentration Ni had opposite effects. It also shows that when Cyperus alternifolius grew in the suitable Ni concentration, chromium absorption in roots was active uptake, and had a strong ability to transfer it. However, high Ni concentration had strong toxic effects on

Cyperus alternifolius, destroyed the root membranes, organelles and cytoskeleton, and declined the roots respiration and leaves transpiration. So the roots absorption of chromium couldn't be transferred to the aboveground initiatively, and resulted chromium accumulation in roots. With the chromium transport capacity weakened, chromium content in aerial part decreased , which was similar to Li's studies[5].

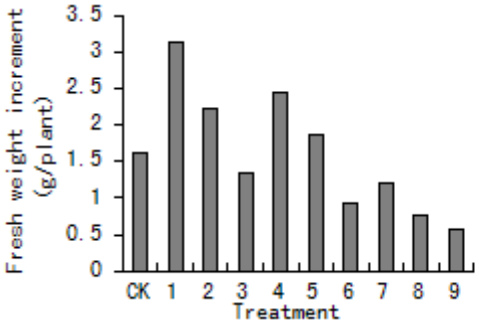

Fig.1 Effect of Cr(VI) and Ni interaction on fresh weight increment of Cyperus alternifolius

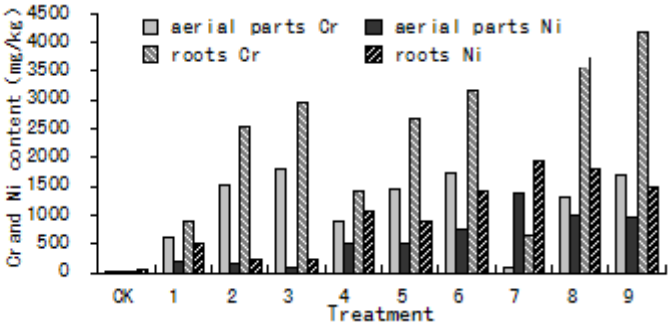

Fig.2 Cr(VI) and Ni contents in Cyperus alternifolius after combined Pb and Zn exposure

Chlorophyll content

Chlorophyll is a necessary catalyst for plants photosynthesis, and plays a important role on plants growth. Chlorophyll content is closely related to the senescence oxidation of the leaf[10]. Combined pollution can lead to the destruction and degradation of chlorophyll, which reflected the forced condition of plants. Seen from Figure 3, under the same Ni concentration, chlorophyll content of Cyperus alternifolius decreased with increasing Cr(VI) concentration. When at the same Cr(VI) concentration, chlorophyll content also showed a downgrade trend. Chlorophyll content reached a maximum of 0.42 $mg \cdot g^{-1}$ when both Cr(VI) concentration and Ni were 1 $mg \cdot L^{-1}$, and was 233.1% significantly higher than that of control. Thus, low concentration of Cr(VI) and Ni combined pollution was conducive to the synthesis of chlorophyll in leaf, showing a synergistic effect. While high concentration inhibited the synthesis of chlorophyll, producing a persecution effect on plants. For the reason, Yuan Min[6] considered that heavy metal inhibited the synthesis of the protochlorophyllide oxidoreductase and affected the synthesis of the aminolevulinic acid, thus reducing chlorophyll content. In this experiment, the decreasing of chlorophyll content may be the combination of heavy metal ions and related enzymes in plants, which changed the enzyme activity to block the synthesis of chlorophyll and affected the biosynthesis rate of chlorophyll, thus reducing chlorophyll content.

SOD and CAT activity.

Under normal growing conditions, the production of reactive oxygen in plants was in dynamic equilibrium, while under adversity stress or aging, the balance between production and elimination of reactive oxygen will be broke. Therefore, SOD and CAT activity changes in plants can characterize the degree of plant stress.

Figure 4 revealed that when Ni concentration was 1 $mg \cdot L^{-1}$, the SOD and CAT activities of Cyperus alternifolius rose at first and went down latter with increasing Cr(VI) concentration, while 10~20 $mg \cdot L^{-1}$, SOD and CAT activities downgraded as Cr(VI) concentration increased. When Cr(VI) concentration was fixed, SOD and CAT activities showed the same trend, but most were higher than under the control. SOD and CAT activities reached the maximum at treatment 4, and were significantly higher than under the control 359.37% and 212.38%, respectively. Results indicated that Cr(VI) and Ni combined stress influence of SOD activity was higher than that of CAT. SOD and CAT activities reached minimum and was lower than the control at treatment 9, showing that high concentration stress destroyed physiological metabolism in plants and inhibited SOD and CAT activities. Therefore, mild stress had a positive impact on active oxygen scavenging system in plants, as a result SOD and CAT activities increased, and they eliminated the free radicals, protected the membrane structure of plants and kept regular growth. While height stress were toxic to SOD and CAT activities, so their activities decreased, the ability of scavenging free radicals downgraded,

functional membrane and enzyme system of plants cells destroyed, physiological metabolic disordered, resulting in the decreasing of plants tolerance, finally[7].

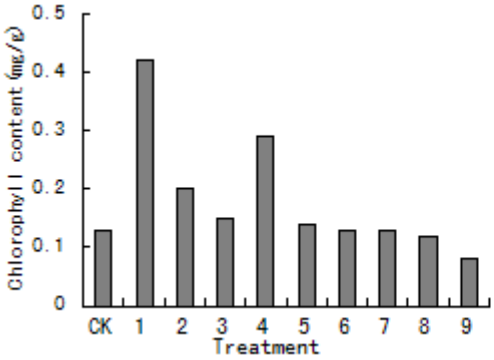

Fig.3 Effect of Cr(VI) and Ni contents on Chlorophyll content of Cyperus alternifolius

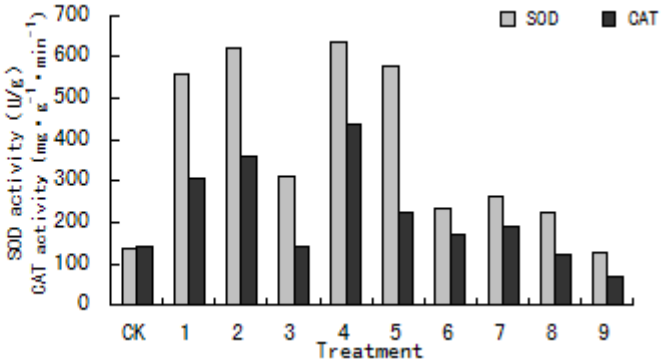

Fig.4 Effect of Cr(VI) and Ni contents on SOD and CAT activity of Cyperus alternifolius

MDA content

MDA as the final product of membrane lipid peroxidation, its accumulation can reflect the level of membrane lipid peroxidation to some extent, thus realizing the damage of plants and the degree of plants stress response. Seen from Figure 5, when Cr(VI) concentration was setted, MDA content of Cyperus alternifolius increased with the increasing of Ni concentration. When Ni concentration was setted, a similar trend was found for MDA content, and was higher than in the case of control group. MDA content had a maximum at treatment 9, it showed that the higher concentration of Cr(VI) and Ni compound pollution was, the more serious the degree of membrane lipid peroxidation had, resulting membrane system stability was lower. This was because added metals impacted the cell structure of biological, made biological membrane lipid occurred peroxidation phenomenon, and damaged the membrane structure, which causing the disorder of cell metabolism in plants and free radicals accumulation, consequently, MDA content rose sharply.

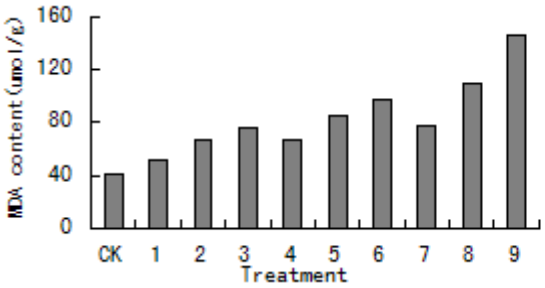

Fig.5 Effect of Cr(VI) and Ni Contents on Proline and MDA content

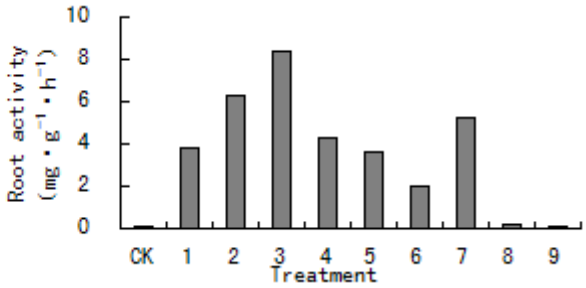

Fig.6 Effect of Cr(VI) and Ni contents on root activity

Root activity

Root is the major organs of plant to obtain nutrients, and root activity was the important physiological index to measure the growing of roots. Figure 6 shows that when Cr(VI) concentration was 1 $mg \cdot L^{-1}$, root activity of Cyperus alternifolius gradually increased with the increasing of Ni concentration, while 10~20 $mg \cdot L^{-1}$, root activity decreased as Ni concentration increased. When Ni concentration was fixed, root activity was also showing the same trend. The analysis of graph revealed that root activity increased at low concentration of Cr(VI) and Ni, having an active effect on the root growth and physiological. On the other hand, it promoted the root uptake of Cr(VI) and Ni and its transfer to the aboveground. But root activity decreased as the concentrations increased, the higher the concentration was, the greater it declined. The possible reason was that free radicals produced went beyond the scavenging abilities of the plant's own antioxidate system enzymes, and excessive free radicals damaged the succinic dehydroge- nase of root metabolism, resulting in root activity decline and the decreasing of biomass[8].

Conclusion

The experiment results show that under Cr(VI) and Ni combined exposure, low concentration Ni improved the enrichment and translocation ability of Cyperus alternifolius for chromium, while high concentration Ni had opposite effects. With increasing heavy metal concentrations, fresh weight increment and chlorophyll content rose at first and went down latter, MDA showed a rising tend and increased significantly.When Ni concentration was between 0~1mg·L^{-1}, SOD and CAT activities of Cyperus alternifolius increased first and then decreased with increasing Cr(VI) concentration, and root activity increased continuously. When Ni concentration was between 10~20mg·L^{-1}, Cr(VI) and Ni interaction decreased SOD , CAT and root activity significantly. In conclusion, Cyperus alternifolius had a strong patience and enrichment capacity to Cr(VI) and Ni, with the addition of the well-developed rhizome and huge biomass, Cyperus alternifolius can be used to restore Cr(VI) polluted water and Cr(VI)-Ni combined polluted water under low Ni concentrations.

Keywords: Externalities; ppp; emission Standards; pigouvian tax;

Abstract. In view of the environmental problems, the paper start with talking about the externality theory and polluter pays principle, and then introduce two kinds of environmental management policy, which are emission standard and Pigouvian Tax. By comparing them in the perspective of economic efficiency, we can learn that: Only the coordination of administrative means and economic measures, we can better solve the environmental problems.

Introduction

Externalities refers that an economic agent has brought the good (or bad) effect, yet he is not been compensated (or cost) for doing so. So we apply it to environmental issues, leading to the concept of environmental externalities. Compared with general externalities, environmental externalities have three characteristics: First, it is inevitable, everywhere and ever-present; second, its effects span a longer period of time; third, an even more important feature of environmental externalities is external diseconomy. So we must take measures to internalize it, that is, as far as possible to eliminate or reduce the environmental externalities. There are two methods to internalize the problem of environmental externalities: one is the market means, or the "invisible hand", which is the famous coase theorem; the other one is the government intervention, namely the "visible hand", which is known as environmental management policy. Environmental exists several problems such as the unclear property rights, high transaction cost, strategic behavior, and ignore the income effect, which limits coase theorem as the main method to solve the problem of environment. Therefore, When deal with environmental problems, we can more rely on government intervention to solve the problem of environmental externalities.

For governments, there are two main management means of environmental externalities, one is direct control policies, also known as administrative measures or imperative means; The other is a environmental economic policy, also known as economic means. Both direct control policies and economic stimulus are based on the theory of polluter pays principle.

Pollution Pay Principle

Environmental management is to correct the external diseconomy of environment and internalize the external costs. And the embodiment of this idea is the "polluter pays principle", which put forward by the organization for economic cooperation and development (OECD) in 1972. The definition of PPP is that the polluter shall bear the cost of controlling pollution losses determined by government to ensure that the environment is in a state of acceptable. In other words, the cost of controlling pollution losses should be included in the cost of products and services, which make pollution in the process consumption or production. The purpose of the polluter pays principle is to internalize of external diseconomy , prompting polluters actively to control pollution, otherwise, they will be suffered economic sanctions.

Environmental management policy and their comparison

Direct control policies--Emission Standards

Emission standards, also known as environmental standards, is one of the most representative methods in direct control means, which is formulated and enforced the maximum limit of each certain pollution by relevant departments. According to the rules, pollutant emission within the limits is permitted, otherwise polluters will be punished, if their pollutants exceed the limits.

As a direct control policies, The advantage of emission standard is certainty, namely to the managers directly control the behavior of polluters and can achieve the effect of environment be expected. However, this method also has great limitations: First, it reduces the economic efficiency. Relevant department needs the detailed information of MNPB and MEC (MNPB is marginal private net income, MEC is a marginal external cost) to determine the optimal drainage standard. Thus, emission standards is generally difficult to achieve the optimal pollution level in the absence of such information. If the government set up a unified emission standard for multiple pollution sources, PPP obviously can not achieve the optimal pollution level of each pollution source; Second, PPP improve the cost management. What cause thus is that many of the sources of pollution is small and scattered. So ,whether get MNPB and MEC information or understand the pollution control cost of various sources can bring expensive management costs; Third, PPP is lack of motivation to stimulate enterprise control pollution automatically. What cause this result is that enterprises don't need to pay cost within the pollutants emission standards, so that enterprises have no incentive to adopt new technology to control pollution. Hence, PPP is not conducive to enterprise's technology innovation and lower the total cost of the pollution.

Environmental economic policies--Pigouvian Taxes

Pigou, a British economist , first put forward a idea that a reasonable price about external diseconomy should be determined by the authority. So, when tax is based on the views of pigou, it was called pigouvian tax. Pigouvian tax, which is imposed on the extent of the damage to the environment, is to use tax to make up for the gap between the private cost and social cost, which make them equal.

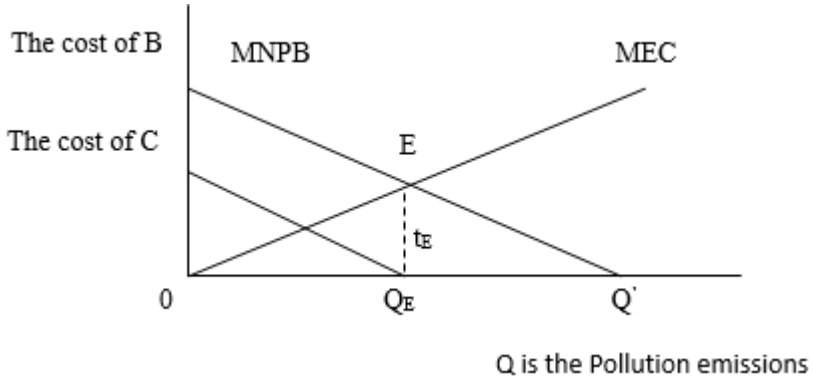

Figure1 Pigou Tax

In figure 1, MNPB is marginal private net income, MEC is a marginal external cost. Although Q_E points is the optimal production scale, the enterprise will produce untile to the point of Q' when MNPB>0. In order to limit production to Q_E, enterprises must be imposed t_E , which is equal to marginal external cost at the optimal output. In a word, imposed tax, which made enterprise's scale of production at the optimal output, is Pigou Tax.

Compare of between emission Standards and pigouvian taxes

Compared with direct control means (emission standard), pigouvian tax has greatly increased the economic efficiency. And the following are their special aspects:

Reduce the standard cost

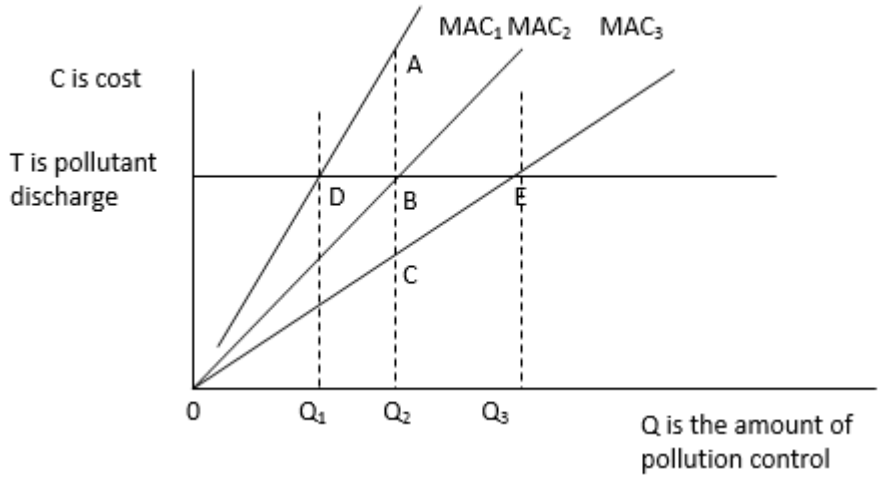

Figure2 Reducing the management cost of Pigou Tax

Assuming that there are three manufacturers in the process of production, the government's goal is to cut the emissions of pollutants to $3Q_2$, $Q_1Q_2 = Q_2Q_3$, and $Q_1 + Q_2+Q_3= 3Q_2$. And in figure 2, MAC_1, MAC_2, MAC_3 respectively said marginal governance cost . It can be learned from the figure is that the cost of factory 1 is highest, the factory 2 times, 3 factory the lowest for the same pollution reduction. If the government set up unified environmental standards and force all manufacturers controlling the emissions to Q_2, the marginal governance cost of factory 1, 2, 3 will respectively reach A, B, C. If the government set the pollutant discharge fee as t, three factories will weigh between discharge and pollution on their own according to the principle of minimizing the total cost. For example, for factory 1, if pollutant emissions is less than Q_1, pollution is much cheaper than paying taxes; if pollutant emissions is greater than Q_1, the result is opposite. In order to compare the total cost between the enforcement emission standard and the pollution charge case, we should calculate the curve under the MAC:

Total governance cost of emission standard: $OAQ_2+OBQ_2+OCQ_2$

Total governance cost of pollution charge: $ODQ_1+OBQ_2+OEQ_3$

And the difference between the two is:（$OAQ_2+OBQ_2+OCQ_2$）—（$ODQ_1+OBQ_2+OEQ_3$）$=Q_1DAQ_2—Q_2CEQ_3$

It can be learned from figure 2 is that the curve of Q_1DAQ_2 is greater than Q_2CEQ_3, so pollution charge of Pigou Tax is lower than simply implementing emission standard cost for controlling the same amount of pollution.

Reducing the costs of the government's management

For emission standard, only confirming enterprise’s pollution exceeded the standard the government can take corresponding measures. For pigouvian tax, the government must confirm that whether the enterprises will produce pollution during the economic activities. So, comparing the cost of doing this, the cost of pigouvian tax is low.

Encourage enterprises to carry out technical innovation.

For emission standards, vendors should not pay a fine if their pollution does not exceed standard, so they have no incentive to seek a low-cost technologies of control pollution.But for Pigou Tax, the pollutant discharge fee is according to the amount of pollutants. So, no matter how much enterprises have the blow down, they must also pay a certain amount of pollutant discharge fee. Therefore companies have incentive to seek a low-cost technologies of control pollution, which can reduce the pollutant discharge fee.

Conclusion

By comparing the two kinds of environmental management policy, we can learn: emission standards is conductive to the fair of environmental resources, though at the sacrifice of economic efficiency. And pigouvian tax can overcome this shortcomings. So in the real practice of

environmental management, the government usually the combine them, namely to the enterprise only pay pigouvian tax within the emission standard, otherwise they not only need to pay the pigouvian tax but also should be fined accordingly. In a word, no matter what kind of policy tools, administrative means and economic measures need to be cooperated effectively, only dong this we can better solve the environmental problems.

Keywords: Low-carbon; Urban transport; System Dynamics; Policy Simulations

Abstract. This paper discusses the connotation of urban low-carbon transport in detail, on the basis of the analysis of low-carbon transport. Combined with the relationship among urban low-carbon transport system elements, the article establishes the system dynamics model. Finally, it simulates the development trends of low-carbon transport in Beijing in the future, and compares the simulation results of different traffic schemes. Moreover, the study puts forward the concrete policy simulations to improve urban low-carbon transport.

Introduction

Over the past centuries, the problem that greenhouse gas caused by the production and daily life leads to global warming has increasingly become the focus of global attention. The concept of "low carbon" was put forward in response to the global climate change and to reduce carbon dioxide in the process of human activities [1]. However, carbon dioxide emissions from the transport sector accounted for a large proportion [2]. Thus, urban transport sector will become one of the important departments in the low-carbon development under the background of the development of low-carbon economy. The low-carbon development path in urban transport of China is not only a crucial way to reduce global warming, but also a new choice to deal with challenges of energy security in China in the future and to achieve the sustainable development of China's urban transportation.

But in the field of low-carbon transport, low-carbon development level in China is relatively low, and research on low-carbon transport system is also less. Thus, this paper gives a correlation analysis of urban low-carbon transport system, and then on this basis, simulates the low-carbon transport trends in Beijing, and puts forward the concrete implementation ways to improve urban low-carbon transport.

Analysis of Urban Low-carbon Transport System

Urban low-carbon transport represents a neoteric development concept and behavior. Its essence is a safe, smooth, orderly and green development mode of traffic with characters of high efficiency, low energy consumption, and low emissions. It pursues dynamic development equilibrium between transportation and economy during the socio-economic development process.

Urban low-carbon transport is to improve transport structure, reduce energy consumption, and control carbon emissions from urban traffic, making per capital energy consumption or per capital carbon emissions a zero growth or even negative growth through traffic demand behavior management and improving transportation organization efficiency, under the circumstance of meeting the continuous growing traffic demand and ensuring the quality of traffic. The connotation can be explained from the following aspects.

First, low-carbon transport is a neoteric development concept. Low-carbon transport does not reduce traffic emissions unilaterally, but reduce carbon emissions or per capita carbon emissions in the transport while ensuring that the quantity and quality of traffic demand of urban residents are not affected and even increasing.

Second, low-carbon transport is a behavior. Low-carbon ways to travel not only reduce carbon emissions caused by the improper selection, also can promote the transformation between existing traffic patterns and low-carbon transport modes, and optimize the structure of traffic travel [4].

Third, low-carbon transport lays emphasis on traffic efficiency. It can not only improve the efficiency of energy use, above all, also to improve the organizational efficiency of the entire transportation system.

Fourth, low-carbon transport is closely related to innovation and application of low-carbon technologies. It can mitigate the growth rate of carbon emissions through technologies, for example, energy saving and emission reduction, development of new energy and tail gas detection and control, thereby achieving the goal of developing low-carbon transport [5].

It can be summed up from the connotation of urban low-carbon transport that urban low-carbon transport system mainly consists of the following seven parts. The interaction among sections is shown in Fig. 1-1.

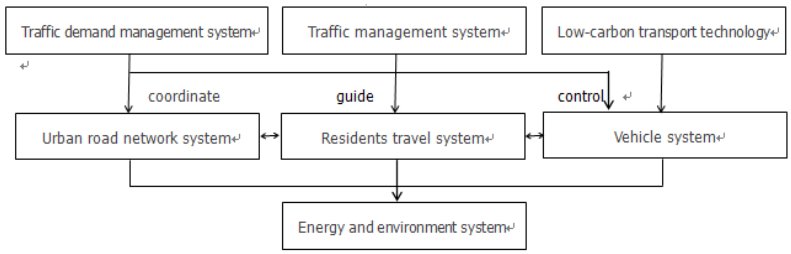

Fig. 1-1 Relation diagram of urban low-carbon transport system elements

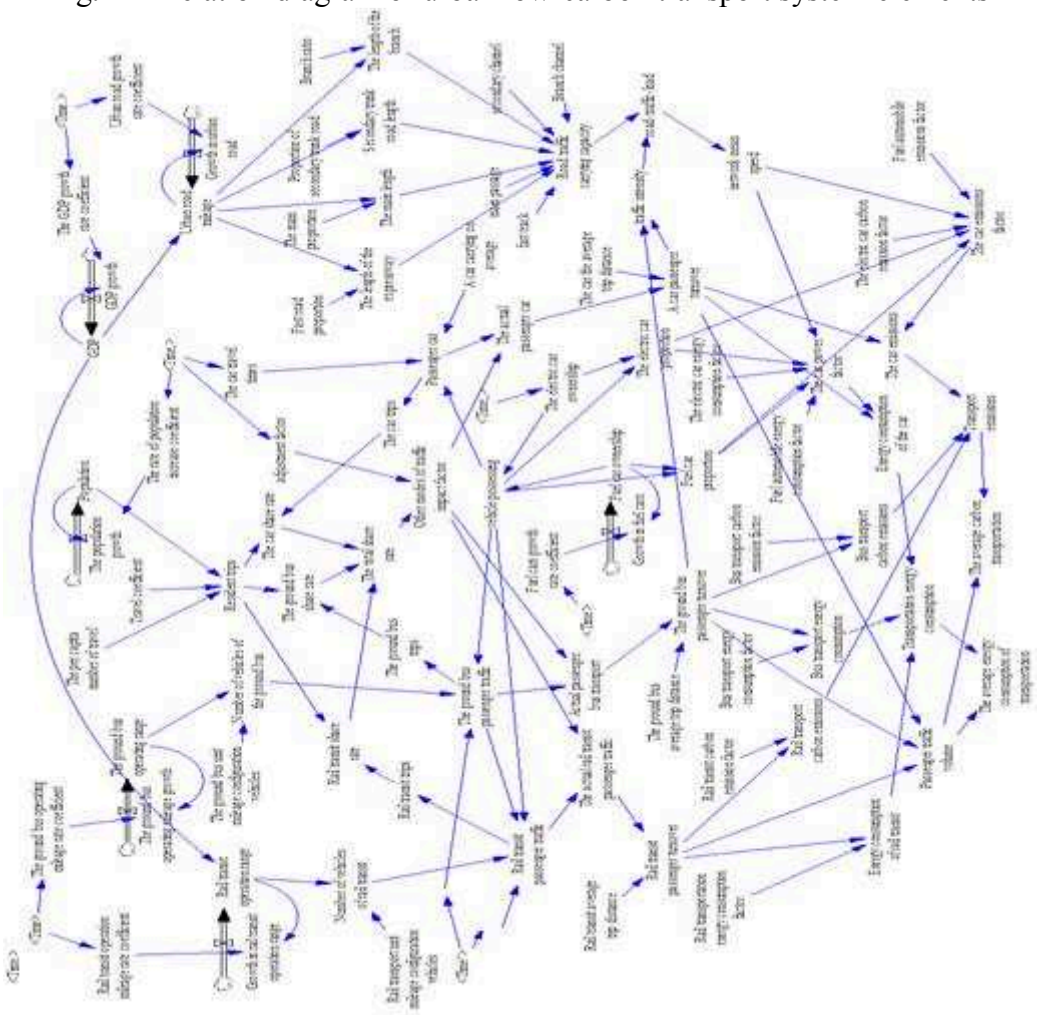

Fig.2-1 System flow chart of low-carbon transport in Beijing

Dynamics Model of Urban Low-carbon Transport System

System dynamics is a simulation calculation method to analyze complex feedback large-scale systems. It identifies the correlation and causality among the elements, according to the object, purpose and nature of systematic research, draws system flow diagram, determines the status, the rate, auxiliary variables of the system, establishes quantitative relations among key variables, and then simulates the overall behavior of the system.

The purpose of this model in the paper is to simulate scenario: change the related variables in the model and observe the effects of its implementation. For instance, the influence of the changes of transportation demands management on the realization of the low-carbon transport, thus getting the feasible suggestions on achieving system goals of low-carbon transport development.

This paper, based on the causality analysis, uses Vensim software to draw up the system flow chart to further distinguish variables' nature, with intuitive symbols depicting the relationship among system elements, and explicates system forms of feedback and control law, as shown in figure 2-1.

The system dynamics model in this paper includes the parameters of urban rail transportation, ground transportation and other aspects of the car. The analysis results of the vital parameters is gotten through the regression analysis of the statistical software SPSS, combined with the statistical yearbook data of calendar year. Some parameters can be estimated according to the transportation development trend over the years [6].

Firstly, rail traffic related parameters. They include the number of rail transit vehicles, vehicle population, ground bus passenger volume and rail transportation passenger volume. Formula is as follows.

$$y = 0.117878x_1 + 62.03115x_2 - 27.865x_3 - 39052.7$$

Where x1 stands for ground transportation passenger volume; x2 stands for rail transportation passenger volume; x3 stands for vehicle population; y stands for number of rail transit vehicles.

Secondly, the ground bus related parameters. They are the number of ground bus vehicles, vehicle population and ground bus passenger volume. The relationship is as follows.

$$y = 26.879x_1 - 123.27x_2 - 16189$$

Where x1 stands for the number of ground bus vehicles; x2 stands for vehicle population; y stands for ground bus passenger volume.

Third, the car related parameters. They are the ownership of fuel cars and electric cars. The latest statistics show that the number of vehicle in Beijing by the end of 2012 has reached 5.2 million vehicles. In order to limit the growth of car, the government in Beijing began to implement a lottery system with an average of 20000 per month on the car number since 2011.Assuming that the numbers are in a stable situation, fuel vehicle growth is about 240,000 vehicles per year in Beijing since 2011, and fuel vehicle ownership has reached to 7.1 million by 2020.

According to the electric car development planning in Beijing, the electric car ownership reached 30000 vehicles by the end of 2012, at the end of 2015 to 109000 vehicles, the growth rate of the electric car is about 0.542. Based on the planning, by the end of 2020, the electric car population has probably reached 960000 vehicles.

Select five state variables to be tested, namely: public transit passenger volume, rail transit passenger volume, bus share rate, rail transit share rate, and car share rate. As shown in Table 2-1. We can see from the table that the error values are controlled within 10%.It indicates that the simulation results are more consistent with the actual situation.

Table 2-1 State variable simulation test results

Time	Project	Actual public transit passenger volume(Thousands of people)	Actual rail transit passenger volume (Thousands of people)	Bus share rate (%)	Rail transit share rate (%)	Car share rate (%)
2005	actual value	369793	67976	24.1	5.7	29.8
	predicted value	367012	67463.2	24.2	5.8	29.9
	relative error	0.75%	0.75%	0.41%	1.75%	0.34%

2008	actual value	470863	121660	28.8	8	33.6
	predicted value	486752	125765	28.3	8.8	31.0
	relative error	3.37%	3.37%	1.74%	9.92%	7.74%
2011	actual value	503272	219280	27.7	13.2	32.7
	predicted value	514139	224014	26.9	13.6	31.6
	relative error	2.16%	2.16%	2.89%	3.03%	3.36%
	average error	2.09%	2.09%	1.68%	4.9%	3.81%

Source: Statistical Yearbook of Beijing, Beijing Traffic Development Annual Report, "Beijing Public Transportation Research Perspective of a low-carbon economy."

Simulation Program of Low-carbon Transport System in Beijing

Scheme one, adjust the car travel times. Reduce the car travel times by 2% per year. The reduced passenger volume of car is usually transferred to the ground bus and rail transport.

Scheme two, adjust the average trip distance of the car. The average trip distance is reduced from 11.49 km to 10 km.

Scheme three, limit the number of fuel cars and encourage the development of electric vehicles. To further reduce the growth rate of fuel cars, assuming that the fuel car growth will drop to 180000 vehicles per year since 2015, and further improve the electric car ownership, from the planning of 110000 vehicles in 2015 to 200000 vehicles, 2020 to 1.2 million vehicles.

Scheme four, adopt integrated program of car demand management. Integrating scheme one, two, three, we should encourage the development of electric cars.

Scheme five, increase investment in public transport and enhance the supply capacity. Operation mileage of rail traffic and bus transportation is increased on the basis of the original planning. Configuration vehicles unit mileage of rail transport are up from 8.5 vehicles/km to 9.5, and bus transportation configuration vehicles unit mileage by 1.12 / km up to 1.8 /km.

Scheme six, increase investment in urban road construction and strengthen the supply capacity.

Scheme seven, carry out comprehensive policy. The policy integrates scheme one to scheme six.

The simulations mainly focus on the influence of the change of variables on transportation energy consumption and carbon emissions. The change of transportation energy consumption and carbon emissions caused by variables' change can be achieved by modifying the relevant variables with the application of simulation model. The simulation results are as follows.

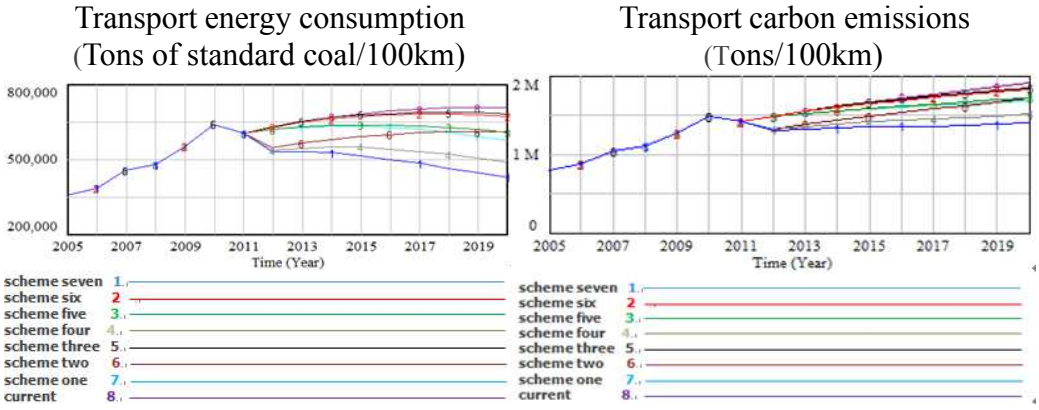

Fig. 3-1 The contrast of implementation effect on transport energy consumption（Left）

Fig. 3-2 The contrast of implementation effect on transport carbon emissions (Right)

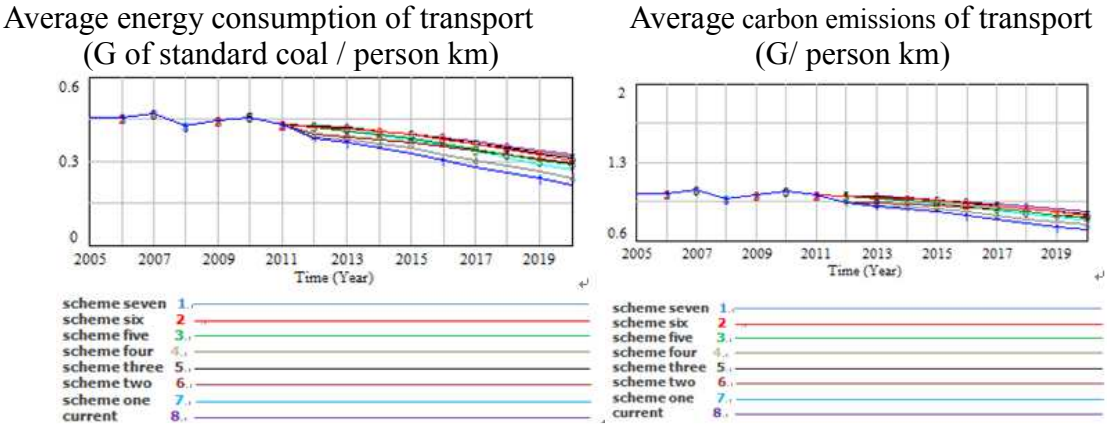

Fig. 3-3 The contrast of implementation effect on transport average energy consumption (Left)

Fig. 3-4 The contrast of implementation effect on transport average carbon emissions (Right)

In order to speed up the implementation of low-carbon transport in Beijing, combined with simulation analysis result, the future development should be focused on the following aspects:

Firstly, promote the building of public transport, and improve its supply ability, thus optimize the urban traffic structure.

Secondly, plan the road network scientifically, optimize network structure, distribute the way reasonably, and reduce the traffic load.

Third, give priority to develop new energy vehicles, such as electric vehicles, through technical innovation, to improve energy utilization efficiency and reduce carbon emissions.

Fourth, advocate low-carbon transport, encourage city residents to establish the low- carbon concept, use the way to travel with low energy consumption and low emissions, such as public transit, bicycles, and walking, provide city residents with a variety of choices to travel to lay a good foundation for low-carbon transport of the city.

Conclusions

This paper simulates the development trend of low-carbon transport in Beijing in the future, based on the related analysis on urban low-carbon transport. The simulation results conclude that the development rate of traffic carbon emissions and energy consumption in Beijing has been reduced than before and the rate of per capita carbon emissions and per capita energy consumption is declining. Those show that the development prospect of low-carbon transport in Beijing is good, and further policy guidance is needed. In addition, the article mainly studies the content about the influence of macroscopic urban traffic management policies on the development of urban low-carbon traffic, not has a further study on the impact of specific technical improvement of low-carbon traffic on system. Considering these, in the future, the traffic structure need to be further improved, and the influencing factor of transport should be considered more meticulous.

The Spatial Effect Identification of Pollution Treatment Investment in China

Liangxiong HUANG [1, a], Min LIU[2, b]

Keywords: pollution treatment, spatial effect, dynamic spatial panel model

Abstract. Pollution treatment investment is an important part of environment protection in terms of energy saving and emission reduction. A dynamic spatial panel model is constructed in this paper, identifying the spatial effect in pollution treatment investment of regions and discussing the mutual influences among different regions. The result shows a mutual positive influence and behavioral convergence regarding to the pollution treatment investment behavior among regions.

Introduction

Nowadays, the society has been exposed to more and more rigorous environment pollution. To solve this problem, pollution treatment investment is becoming a rising concern. On one hand, pollution treatment investment can powerfully help to mitigate the degree of loss on pollution; on the other hand, it can effectively prevent the potential emission. Besides, the externality of treatment and the local background of China: "centralized polities and decentralized economies", together cause the mutual influence on pollution treatment among different areas and form spatial effect. This paper focuses on the discussion upon the spatial effect of areal pollution treatment investment, taking the every ten thousand yuan GDP industrial pollution control project investment as the analysis object. Unit GDP pollution treatment investment reflects the strength of areal pollution treatment. Moreover, it is a qualified corresponding variable of emission quantity and energy consumption of past researches.

The spatial effect of pollution treatment investment among different areas, or mutual influence between areas, may be positive or negative. If the spatial effect is positive, it means pollution treatment investment behaviors among areas are positively correlated, the areas will converge with each other in the pollution treatment investment behavior; otherwise, they will diverge.

The empirical models and methods

In order to study the behavior characteristics of pollution treatment investment in China's provinces and analyze the spatial effect of pollution treatment investment, a spatial panel model is constructed [1]. The specific regression equation is as follows:

$$P_{it} = \theta_0 + \theta_1 P_{it-1} + \rho W * P_{it} + \psi X_{it} + \varepsilon_{it}$$

In the above equation, P represents unit GDP pollution treatment investment in the region. This paper adopts three pollution treatment investment indexes, which are industrial pollution treatment investment (*lginvt*), industrial waste gas treatment investment (*lginva*), industrial waste water investment (*lginvw*). The three indexes also respectively reflect the performance of the overall environment treatment, gas pollution treatment and water pollution treatment in the region. W represents spatial weight matrix. $W \times P_{it}$ reflects the effects of investment in other regions on the local region. The coefficient ρ represents the direction of the effects. If ρ is significant, it also indicates that the local investment has significant effects on other regions' pollution treatment. On the other hand, the pollution treatment investment of regions is always time-dependent; the investment in the past time will affect the current investment. To indicate this point, a time lag

phase is put in the regression equation. Thus, the above equation includes the lag phase of the explained variable and the spatial weights, forming a dynamic spatial panel model. The former captures time change effect, and the latter captures the spatial effect of regions.

X is controlled variable, including three categories: firstly, variables that reflect the environment factors of regions mainly including Carbon dioxide emissions per unit of GDP (*lgco2*), wastewater emissions per unit of GDP (*lgwat*) and the effective tax rate (*el*); Secondly, variables that reflect the economic structure factors, mainly including real per capita GDP and its squared term (*ly&ly2*), the proportion of Second industrial added value of GDP (*wg2*), external dependence degree (ti) and urbanization rate (*cir*). Other controlled variables, mainly average years of education (*pey*), density of population (*lpopa*).

The spatial weight matrix

Spatial weight matrix W is a $N \times N$ symmetric matrix, The diagonal elements W_{ii} set as 0. And it indicates the correlation of the region i and region j. Here three kinds of weighted matrix are used, firstly, the spatial weighted matrix based on the spatial distance, namely $W_{ij}=1/d_{ij}$. Secondly, the Rook adjacent spatial weighted matrix (*Wr*), it is $W_{ij}=1$ when two areas have a common boundary; it is $W_{ij}=0$ when two areas do not have a common boundary. Moreover, in the robustness test, the K value of the adjacent space matrix (*Wk*) is also used. Given a space unit, the weight is 1 when selecting the nearest *K* areas, otherwise zero. Generally, *K* is 4. Meanwhile, to eliminate the external influence among areas, the weighted matrix is standardized as $W_{ij}^{*} = W_{ij} / \sum_{j=1}^{N} W_{ij}$, which makes the total sum of the elements of the row equal to one.

Empirical Analysis

According to the equation (1), a dynamic spatial panel model is constructed, studying the spatial effect of pollution treatment investment of regions, and the results are presented by table 1. As in the right of the equation (1), there is endogeneity both in the time lag and the spatial weights of the explained variables. To solve the problem of endogeneity, by the method of Huang et al. [2]—the spatial systematic GMM estimators (SBB) and spatial difference GMM estimators (SAB) are used to estimate it.

The estimators that Table 1 built show that Moran'I statistics are significant, which means China's regions per unit of GDP investment environment pollution has spatial dependence. At the same time, AR (1), AR (2) and Hansen statistic result show that the selected IV in this chapter variable is reasonable.

The spatial effect coefficient ρ which reflects the pollution treatment investment is analyzed. The results show that the spatial weighted coefficients of industrial pollution treatment investment (*lginvt*), industrial waste gas treatment investment (*lginva*) and industrial waste water investment (*lginvw*) are significantly positive, indicating that the investment of unit GDP of other regions has significantly positive effect on the local region. In turn, if the spatial weighted coefficient ρ is significantly positive, the investment of unit GDP in the local region has significantly positive effect on other regions. Therefore, the investment of unit GDP among regions has mutual positive effect. The behaviors on pollution treatment investment among regions are consistent, resulting that unit GDP pollution treatment investment of close regions is adjacent to each other and spreads out. Convergence is reached finally. Similar analysis can be found in Huang et al. (2011) and Shu and Huang (2012). The former found that the pollution of the developed areas in China has "example effect" to the other areas, that is, the developed areas of sewage pose significant positive influence to the rest. The latter also found that there is positive influence among regions on each other in our country environment pollution resources loss.

There are two reasons for the positive mutual influence of areal pollution treatment investment behavior. Firstly, since environment is public goods, there is positive externality of pollution treatment, which will benefit not only the local region, but also others. However, such mechanism makes the marginal private benefit of pollution treatment less than that of the marginal social benefit. There will be a problem of free riding. At this time, no one will actively treat the pollution, so that the level of social pollution treatment will be lower than the optimal one. In other words, if no central restriction exists or the restriction is not strong enough, pollution treatment investment behavior in different regions will converge, which means regions will reduce pollution treatment investment as much as possible. The second reason is the stronger decision power of local government on pollution treatment investment than that on emission amount. As is known to all, the reducation of emission amount depends much on technology which in short term has quite limited advancement. However, another variable affecting the pollution treatment, investment, can be easily adjusted according to governments' plans. So the local governments of regions show more strategic interaction feature on pollution treatment investment. The significantly positive ρ value also shows that strategic complementation exists among different regions, as the regions imitate each other on pollution treatment investment behavior [3].

Robustness Test

In this section, robustness test is taken, mainly replacing the spatial weighted matrix and using the matrix based on adjacent method *(Wr*), SAB estimator and MASARAR (1, 1) model used by Wang (2010). Table 2 shows the results.

Both in the SAB estimator and MASARAR (1,1) model, the spatial effect coefficient ρ which reflects the pollution treatment investment of regions is significantly positive. The pollution treatment investment behavior has mutual positive influence, going to convergence.

Table2 Robustness test: using different regression model

		SAB			MASARAR(1, 1)		
		lginvt	*lginva*	*lginvw*	*lginvt*	*lginva*	*lginvw*
Wd	ρ	0.901***	0.758***	0.856***	0.757***	0.813***	0.920***
		(0.101)	(0.139)	(0.108)	(0.181)	(0.188)	(0.190)
Wr	ρ	0.603***	0.398***	0.637***	0.532***	0.586***	0.629***
		(0.082)	(0.086)	(0.084)	(0.184)	(0.267)	(0.207)

Moreover, after the author replaces the spatial weighted matrix by using the nearest spatial weighted matrix (*Wk*) of K=4, and constructs SBB and SAB estimators and MASARAR (1, 1) model, the coefficient ρ is still significantly positive, indicating the robustness of the results.

Conclusions and policy recommendations

Pollution treatment investment is a necessary measure for environment protection and green development. In the context of Chinese political centralization and economic decentralization, regional issues are often rooted in the interactions among regions; these interactions will form the space effect. The analysis of Chinese pollution treatment investment is not an exception. This paper uses the dynamic spatial panel model, builds SBB and SAB estimators, and combines with MASARAR (1, 1) model to investigate the spatial effect of areal pollution treatment investment to explore the interactions among regions. The results show that:

Unit GDP of areal pollution treatment investment has a significant positive effect, which means regions converge on pollution treatment investment behavior. This paper argues that the conclusion is based on two points. (1) Like the pollution emissions, pollution treatment investment has externality, and the externality is positive. A regional pollution treatment investment can make other regions benefit without costs, and then it comes the regional "hitchhike" phenomenon. Because there is few restraints to this phenomenon by the central government, represented by the lack of constraint strength, provinces tend to reduce pollution treatment investment. (2) The regional competition currently is still dominated by the GDP competition and governments' passion for pollution treatment lag far behind economic growth. However, there are regional interactions of imitating each other's strategy, so regions will tend to make pollution treatment investment in the constrained standards even though the central constraints are hard.

To eradicate the externality of pollution emissions and pollution treatment and eliminate the phenomenon of market failure, government needs strong promoting policies. So the key is to arouse the enthusiasm of local governments, which can start from the current local government (officials) assessment mechanism. If the evaluation mechanism of taking GDP as the single core is not changed, there will not be enough stimulation to the local government (officials) to control pollution. And the lack of hard constraints will also lead to regional race to the bottom. The implementation of "one vote veto" system and accountability system can make hard constraints to environmental indicators, which can cause the local government's attention but let the pollution level remian in the constrained standards. This setting only guarantees the lowest level but cannot obtain a better level. So deepening the assessment mechanism and introducing the multiple target mechanism should be the future direction of development. For example, using the environment satisfaction of the local residents is conducive to form the scale effect of environmental governance, to promote energy-saving and emission reduction, and to promote environmental protection in the area. The double yardstick competition of GDP and environmental governance will promote a sound and rapid development of our country with not only faster economic growth, but also environmental improvement.

Keywords: Beijing, $PM_{2.5}$, PM_{10}, Haze, Continued

Abstract. Three consecutive severe traffic monitoring points collected in different atmospheric particulate pollution concentrations data during February 2014 in Beijing. The results show that the hourly mean concentration of $PM_{2.5}$ often exceeded 200 ug/m^3, with a maximum concentration of 300 ug/m^3on Feb.22,2014. The hourly mean concentration of PM_{10} either exceeded 258 ug/m^3.The concentration of $PM_{2.5}$ and PM_{10} was significantly increased during haze events, especially $PM_{2.5}$ concentrations increased gradually and a slight decline in the middle, then rise.

Introduction

Atmospheric particulate matter, atmospheric aerosols dispersed systems of various particles. According to aerodynamic equivalent diameter, can be divided into total suspended particulates, repairable particulate matter and fine particulate matter. Total suspended particulate matter is the particle size <100um all particulate matter, expressed as TSP (total suspended particulate); Particulate matter refers to a particle size of <10um particle, expressed as PM_{10} (inhalable particulate matter); particle size <2.5um of particulate matter is known as fine particulate matter, expressed as $PM_{2.5}$ (fine particulate matter)[1]. Compared with coarse atmospheric particles, fine particulate matter is rich in a lot of toxic and hazardous substances and long residence time in the atmosphere, conveying distance, and thus a greater impact on human health and environmental quality.

Beijing is experiencing heavy air pollution in the past two decades, with particle matter (PM) being one of the top pollutants (Chan and Yao, 2008).PM especially fine particles often exceed the new National Ambient air Quality Standards of China ((75ug/m^3 for 24 h average) (Sun et al.2013)).Ambient air quality standard is shown in Table 1.Fine particles have a large impact on visibility. Therefore, haze events (with visibility<10 km) appear frequently in Beijing with high concentration of fine particles. [2]Paper studies during the Beijing haze, PM2.5 and PM10 concentrations and changes in variation.

Table1. Ambient air quality standard

Pollutants	Average time	Concentration limits		Unit
		one-level	second level	
SO_2	Annual	20	60	ug/m^3
	24-hour	50	150	
	1-hour	150	500

	24-hour	80	80	
	1-hour	200	200	
CO	Annual	4	4	ug/m^3
	24-hour	10	10	
	1-hour	100	160	
Particulate matter（article size of <10um）	Annual	40	70	
	24-hour	50	150	
Particulate matter（article size of <2.5um）	Annual	15	35	
	24-hour	35	75	

Data collection and analysis

Collection point. As to 2013, Beijing has established 35 monitoring points, including 12 monitoring points urban, suburban 11 monitoring points, seven points and control points and five regional traffic pollution monitoring point. For CO, NO2, O_3, SO_2 concentration of repairable particulate matter 24-hour real-time automatic monitoring, accumulated a large amount of data, which has a very important significance for the study of air quality and characteristics of Beijing. In this paper, data from previous Gate East Avenue, South Third Ring Road, East Fourth Ring Road, three traffic pollution control points collected for the study, analysis of many types of pollutants.

Collection and analysis.

Data collection: Every evening at six to export the data, the data is updated once every hour, 24 hours a day for pollutants real-time automatic monitoring, primarily to monitor CO,NO_2, O_3, SO_2 and the concentration of repairable particulate matter, the study of $PM_{2.5}$ and PM_{10} concentrations finally study the variation of the fog and haze.

Data processing: The data collected mainly by way of text files and databases to manage things [2], and displayed in the form published on the website, to achieve the basic storage function, but the need for further post-processing. Research platform to use VB.NET to create air quality data management system, using powerful computers to achieve automatic analysis of air quality data processing, automated data management of air quality in Beijing.

Data Analysis: Take 20 to 27 February $PM_{2.5}$, the average daily PM_{10}concentrations, and compare it to study the relationship between visibility.

Results and Discussion.

The average concentration of PM2.5 and PM10 during fog and haze .Table 2 showed, $PM_{2.5}$, PM_{10} pollution is serious, three sampling points PM_{10} , $PM_{2.5}$ on February 22 average concentration (unit: ug/m^3) were 260.78ug/m^3, 267.45ug/m^3, 255.56ug/m^3 and 214.81ug/m^3, 135.3ug/m^3, 258.79ug/m^3. According to Chinese air quality environmental quality standards (GB3095-2012), the average PM_{10} concentrations three points (202.9ug/m^3) more than two standard prescribed daily average (150ug/m^3), the average $PM_{2.5}$ concentration (261.3ug/m^3) far more than two class standards prescribed daily average (75ug/m^3) [3].

Table2. Feb.22.2014 PM_{10} and $PM_{2.5}$ concentrations in Beijing

Monitoring points	PM2.5 concentrations (ug/m^3)		PM10 concentrations (ug/m^3)	
	Concentration range	Mean	Concentration range	Mean
Yongding Gate Avenue	220—306	260.78	110—375	214.81
South Ring Road	214—312	267.45	105—186	135.3
East Fourth Ring Road	199—352	255.56	154—435	258.79

Whether PM_{10} or $PM_{2.5}$ concentration monitoring points are far greater than the standard value, in fog and haze, the concentrations of $PM_{2.5}$ will continue to rise, especially under low visibility fog and haze conducive to the accumulation of particulate matter, resulting in high concentrations of aerosol pollution events [4]. Figure.1 is the trend of $PM_{2.5}$ and PM_{10} in fog and haze. As can be seen from the figure1, the value of $PM_{2.5}$ and PM_{10} uptrend in three monitoring points, with the haze of pollution increase, its value also will increase. Thus, in the fog and haze, and have the concentration increases, which also is consistent with previous studies [5].

During the haze, larger temperature difference between day and night, Beijing, and has been in the breeze among the lower wind speeds are less than three, is not conducive to the spread of pollutants. Lower ground moisture and high wind speeds and humidity often causes the rapid accumulation of growth, and a large temperature difference between day and nighttime radiation inversion makes clear that while the existence of inversion tends to inhibit the spread of pollutants, making transportation difficult at low altitude to high altitude .[6] It can be seen in the haze sustained period of time, the weather conditions are not conducive to the spread of pollutants, but is conducive, accumulation, making the fog and haze last many days, it is difficult to dissipate. In the 27th, night of rain, making the weather improved, showing that meteorological factors are the key factors of fog and haze now resolved.

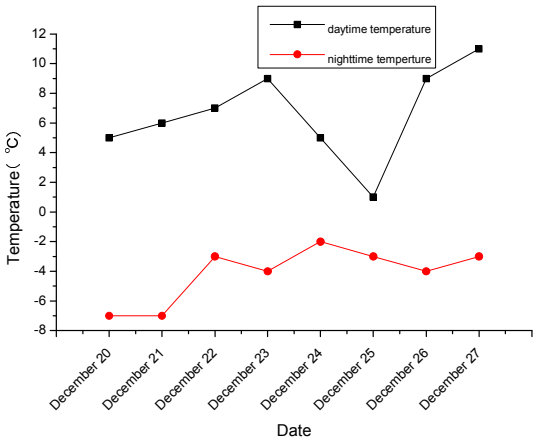

Fig.1.Changes in $PM_{2.5}$ concentration curve

Conclusion

Under fog and haze, and the concentration of $PM_{2.5}$ were 267.45 ug/m^3, 260 ug/m^3, which is higher than the national standard concentration 150 ug/m^3, the concentration is higher than the national standard 75 ug/m^3 significant, indicating that in the fog and haze have significantly increased and the concentration .Beijing meteorological factors not conducive to the spread of pollutants, making the fog and haze last longer, making it difficult to low-altitude water vapor, to form a stable boundary layer near the ground, in order to provide a better generation and accumulation of $PM_{2.5}$ add conditions.

Keywords: Urban River; Enhanced Nitrogen Removal; Ecological Engineering; Water Purification

Abstract. Based on the biological purification technology combined with the engineering measures, the enhanced nitrogen purification biological experiment is implemented in Wenyu River in Beijing. The water in the river mainly is the outflow from the sewage treatment plant, in which the ammonium (NH4-N) has been effectively removed for the deeply nitrification, while treatment of the nitrate nitrogen (NO3-N) and total nitrogen (TN) is incomplete due to the denitrification. The water has low C/N value and has poor biodegradability. In this study, aiming at the water feature of low C/N and poor biodegradability, the effective way to strengthen denitrification by some enhanced techniques, such as increasing the microorganisms number and biodegradability (ie, improved nitrogen ratio), changing denitrification rates and so on, has been studied. The experimental results show that under the condition of water flow (Q) as 15 ~ 27L/hr, hydraulic detention time as (HRT) 10 ~ 18h, concentration of nitrate nitrogen (NO3-N) as 12.20 ~ 31.44mg / L, and total nitrogen (TN) as 14.50 ~ 34.71 mg / L, the removal rates of NO3-N and TN are over 30%.

Introduction

Wenyu River is the only river started from Beijing and flows in the whole year. It is a main stream for the flood control, drainage, irrigation and ecological environment protection, and it is also a river for the city sewage water. Wunyu River plays an important role for the urban socio-economic development and urban construction.

With the rapid development of the economic and the urbanization, the urban population increases dramatically, and the discharge of sewage water of industry, agriculture and domestic waste water are also increasing. Due to the lag of watershed drainage network and sewage treatment infrastructure, the river water has been polluted and water ecology has been degraded, therefore the function of the river resources, environment and ecology are lost.

In recent years, the Chinese government places great emphasis on environmental protection, and the waste water treatment rates rise constantly. The techniques of denitrify and dephosphorization cause high energy-consuming, low removal rates and the unstable running operation, therefore the outflow has high concentration of N and P, specially when the Ammonian (NH3-N) transfers to trate nitrogen passing the high Oxygen consumption area with incomplete denitrification and resulting the increasing trate nitrogen. The removal rate of total nitrogen (TN) of the waste water outflow is low, which leads to high harmfulness when the outflow is discharged to the water environment[1].

According to the current sitiation of Wenyu River, building the waste water plant to achieve the deep water purification to is impracticable because of the infrastructure investment and operating costs. The ecological projects embedded in the water courses in the river is applied to enhance the denitrification treatment process, which can also relieve the pressure on municipal infrastructure construction and sewage treatment plants, in the meantime it can beautify the natural environment,

to solve the pollution problem. an effective method of purifying water strengthening The ecological projects can be an effective method to strengthen the water purification.

Design of the Experimental Mechanics

According to the current water quality characteristics of Wenyu River, the purpose of this study is to enhanced denitrification process and to intensify the water purification of the waste plant outflow. Due to the low biodegradability of the urban river water against the denitrification process, in order to improve denitrification efficiency the experiments are designed to increase systemic biodegradability and change the denitrification way as "enhanced techniques" by increasing the number of microorganisms[2] [3] [4].

Based on the nitrate removal theory, in the experiments, the glucose is regarded as carbon source, and the elemental sulfur as an electron donor into the reaction system to promote autotrophic denitrification. The impacts of the supplement to improve the biodegradability of nitrification and changing nitrification approach on denitrification are analyzed [5] [6].

Considering the river water characteristics in the field remediation technologies in the experimental schemes, the experiments has designed "eco-reactor (channel)" (hereinafter referred to as eco- groove) as a new treatment techniques, which take advantage of natural conditions to make the river run freely to reduce energy consumption and operating costs.

The main unit in the experiments is eco-groove (ditch) with the size of 200 cm × 30 cm × 50 cm, effective depth 45 cm, and total effective volume 270L. The eco-groove is divided into two layers by the multi-stepped perforated clapboards, to form 2 spaces as aerobic and anaerobic zones, with the volumetric ratio as 1:2. The walls of eco-groove are covered with aluminum foil to prevent light in, and to simulate the working environment of the river ecological engineering. The inlet is in the aerobic zone, and the effluent outlet is in the anaerobic zone. The certain giving water discharge and level are used to control the constant flow in the experimental zone.

There are three study cases by using different hydrodynamic operation situations with the same specified eco-grooves numbered as I, II and III. The study is designed to do the comparison among those cases.

The cabinets of the eco-groove are made of plexiglass and plastic plates. The main parts of the devices include the water inlet and outlet, pumps, flow meters, and the auxiliary equipments includes water storage tank, mixing tank, access to water, water gauge, submersible pumps and so on. The devices of eco-groove are shown in Figure 1.

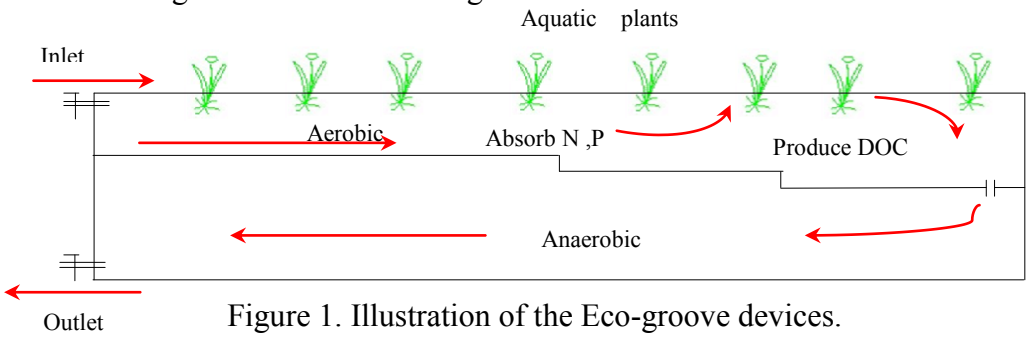

Figure 1. Illustration of the Eco-groove devices.

Water quality condition in experiments

The tests water in experiments is taken from a section of Wunyu River in a town in Beijing near. The indexes of water quality are indicated in Table 1.

Table 1. Water quality indexes in the raw ware in the experiments

Indexes	pH	COD (mg/L)	NH4-N (mg/L)	NO3-N (mg/L)	TN (mg/L)	PO4-P (mg/L)	TP (mg/L)	TOC (mg/L)
Range	6.4~8.2	10~20	0.2~4.8	12.2~31.4	14.5~34.7	0.9~4.9	1.3~5.7	0.18~0.32
Average	7.3	15	2.3	21.8	24.6	2.9	3.5	0.25

Seen from Table 1, the water has low the concentration of COD and NH4-N, and TN mainly in the form of NO3-N, and the C/N is relatively low, which means that the water has poor biodegradability.

Methods of Water Quality Analysis

To measure the different indexes, we use the spectrophotometry UV for NO3-N, the Nessler's reagent spectrophotometry for NH4-N, the potassium persulfate - UV spectrophotometry TN, the non-dispersive infrared absorption method for TOC, the temperature using rapid analyzer for DO, and the portable pH meter for pH, the potassium permanganate oxidation for COD.

Experimental operating conditions

Three experiments with different operating conditions are designed according to the real sewage treatment method. To improve the preliminary understanding of the denitrification functions of the eco-groove, we run designed three cases.

Groove I is a comparing tank without any medium, and it is used for the tests under sewage water conditions only;

Groove II is used for the ecological method, in which we supply the carbon source, increase C/N, improve water biodegradability, and promote denitrification. Some amount of aquatic grass and agave fiber are transplanted on the upper cavities of the groove. In the meanwhile, the five-week advanced pre-domesticated cultivated microorganisms in the anaerobic process in a sewage treatment plant are transferred into the test section [7].

Groove III is used for the denitrification function study of the anaerobic microbial metabolism. The spherical cavity biofilm carrier and elemental sulfur which have been domesticated and cultivated in the anaerobic process in a sewage treatment plant for 5 weeks, are added in the groove III [8].

The experiments start to operate in about 70hr's cultivation.

The inflow condition in three cases are the same. The water flow (Q) is 15~27L/hr, the hydraulic retention time (HTR) is 10~18hr, and the temperature(T) is 16-26℃.

In addition, when the cases are in the stable operation stages, the carbon sources are supplied in the ecologically tank to study the impacts on the denitrification function of increasing carbon[10].

The cases are continuously operated, and water temperature, pH, dissolved oxygen (DO), nitrate nitrogen (NO3-N and NO2-N), total nitrogen (TN), total organic carbon (TOC) etc al are monitored dynamically. The effects of enhanced denitrification and purification are analyzed through the experimental results[11][12].

Experimental results and discussion

Changes of dissolved oxygen and removal efficiency of trate nitrogen and total nitrogen

Because the inlets of the ecological groove in 3 cases are located in the upper cavities, and the same water conditions are used, the water qualities in upper cavities are used to indicate the water qualities. The evolutions of DO concentration against operating time in the 3 cases are shown in Figure 2.

As for the dissolved oxygen, it is in saturated oxidation state in upper cavities during the whole operation process. The fluctuations of DO are consistent with the daily period of sunshine and photosynthesis. The DO reduces in the below cavities. After about 72 hours, microbial environment is gradually developed till completed, and the oxygen consumption of organic matter degradation lead to anaerobic or completely anoxic states, so that DO maintains at a low level, which provides denitrification environment for the nitrate nitrogen.

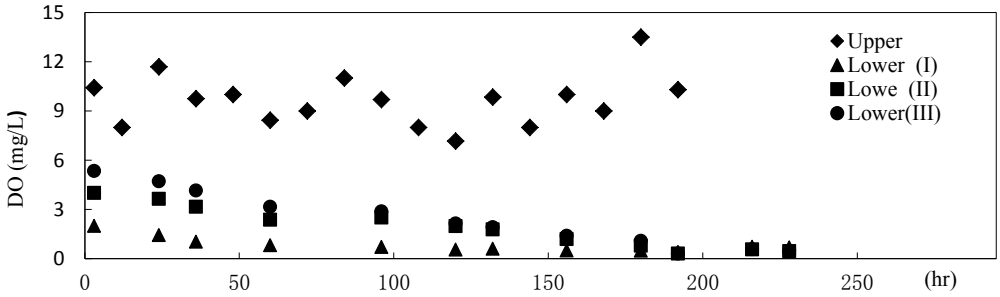

Figure 2. The evolutions of DO concentration

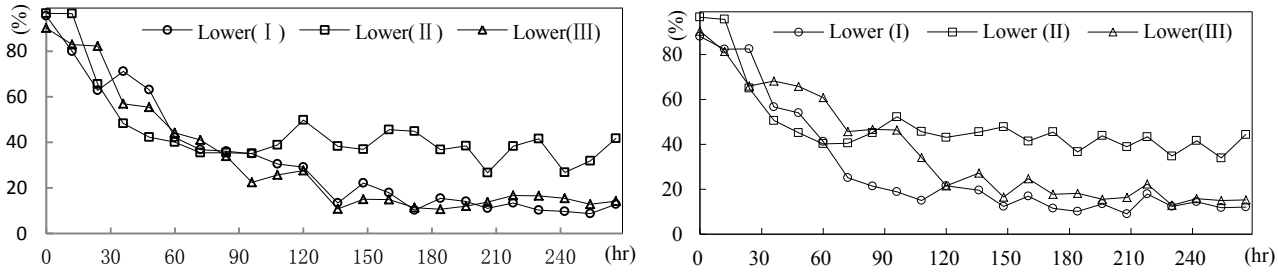
The saturated oxygen situation in upper cavities does not have denitrification condition. The measured results also have confirmed this point. Therefore, in this paper we only analyzes the denitrification function under anaerobic or completely anoxic environment. The removal ratios of nitrate nitrogen and total nitrogen against operating time are shown in Figure 3(a) and (b).



(a) The removal ratios of NO3-N (b) The removal ratios of TN

Figure 3. The evolutions of removal ratios of nitrogen

Because the experiments run after cultivation of microorganisms, anaerobic denitrification \performs strongly in the first 72 hours due to the mixing process between the influent water and original water. After 72 hours, the experiments get into the stable states, and the nitrate nitrogen denitrifications in the lower chamber are significant different among the three cases under the condition of anaerobic or completely anoxic.

The results have indicated that nitrate nitrogen and total nitrogen averaged removal ratios were 14.11% and 15.32% under operating conditions in the tank I. With the supplement of biological material and elemental sulfur were added in the tank III, the averaged removal ratios nitrate nitrogen and total nitrogen are 15.02% and 16.10%, which raised by 0.99%和 0.78% respectively comparing with those in tank I; The increase of microbial biomass is one of the factors which promotes the denitrification efficiency. The elemental sulfur, as the electron donor, improves the anaerobic metabolism of dissimilatory nutrient microbes, and change the way of denitrification. After adding the biological amterial (cultivated) and elemental sulfur in the tank III, the denitrification rates increase slightly, but have no significant improvement comparing with the tank I. It showed that for the water with poor biodegradability , the increase of microbial biomass and change of denitrification's way are not the only determining factors of denitrification. When added the biological material (cultivated) and aquatic plant in the tank II the denitrification rates improve remarkably, and the nitrate nitrogen and total nitrogen removal rate reaches 37.15% and 39.05% on average, which increased by 22.94% and 23.73% respectively comparing with the tank I. Under the conditions of anaerobic or completely anoxic, the aquatic plants are planted in the tank II, which supplys the organic carbon and increases the C/N of water, increases microbial biomass, and promotes the denitrification remarkably as a result. It shows that for the water with poor biodegradability, the addition of organic carbon and improvement of biodegradability are the key techniques to realize the denitrification under the condition of enough biomass. Additionally, the experiment results indicates that in the stable running state, the nitrate nitrogen and total nitrogen removal rates show the regular fluctuation between day and night after adding aquatic plant in the tank II, and the highest removal rate is in the midday and lowest is in the midnight, which are in accordance with the inter-diurnal variations of microbial activity.

The impact of carbon source on nitrogen removal efficiency

The experiments indicated that the supplement of the organic carbon and increasing the C/N (The C/N describes in this paper is the mass ratio of the added glucose carbon and total nitrogen in water) and improving biodegradability are the key factors to affect the nitrogen removal efficiency.

To study the relationship of organic carbon and the nitrogen removal rates and the best ratio of C/N to keep sufficient biomass, we designed another experiments the same as the tank III which add glucose and C/N in four proportion of 1, 3, 4 and 5. The nitrate nitrogen and total nitrogen removal rate curves are shown in Figure 4. The nitrate nitrogen removal rates are 47.93%、81.31%、93.21% and 91.92%, and the removal efficiency of TN was consistent with the NO3-N, shown in Figure 4. When C/N equal 4, The nitrate nitrogen and total nitrogen removal rates are the highest. While when C/N is 5, the total nitrogen removal rate was relatively low, and it might be because the carbon source is relatively superfluous, which restrains the activity of other bacteria but denitrifying bacteria in the anaerobic environment. Therefore, the nitrate nitrogen removal rate is fairly flat, and the total nitrogen removal rate is lower than that when C/N is 4.

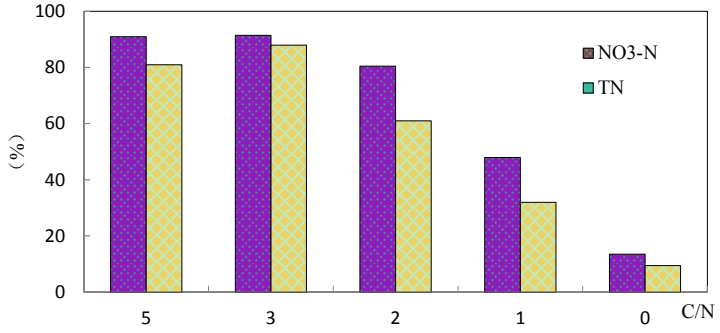


Figure 4. Denitrification efficiency under different

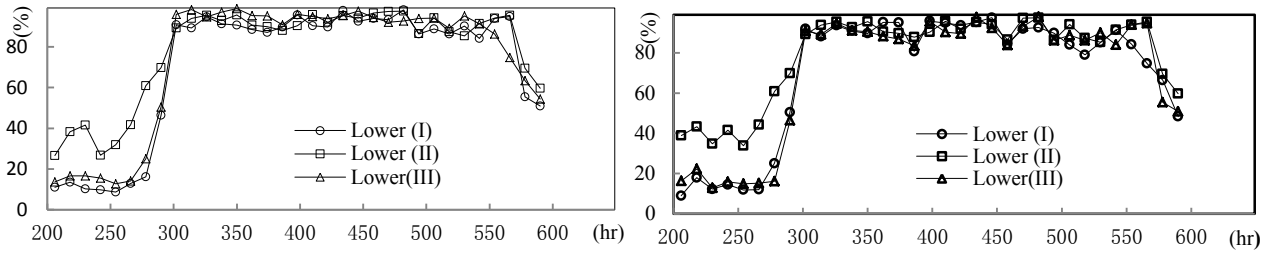
The above results show that the addition of carbon source could greatly enhance the denitrification of the system. When the supplementary of carbon source is none or little, the denitrification is unsatisfactory. But when the extra amount of carbon source exceeds a certain value, the denitrification rate had no significant change. According to the above experiment result, the best C/N for denitrification system of ecological slot is 4.

To enhance the denitrification efficiency, we increase the available activated carbon (glucose)and check out the efficiency of ecological slot with multiple criteria under the condition of increasing the number of microorganisms and changing the way of denitrification.

We add glucose in terms of C/N=4 in tank I, tank II and tank III, the result was shown in Figure 5(a) and (b).



(a) The removal ratios of NO3-N (b) The removal ratios of TN

Figure 5 . Removal curves of the nitrate nitrogen and total C/N nitrogen in 600hrs

In Figure 5, the first 260 hours is the continuous operation processes of the last experiments. The denitrification rates of tank II keep in 30-40%, and that of the tank I and tank III are low. After the glucose adding, the denitrification efficiency of the three tanks enhances significantly. Through the continuous operation from 260 hours to 600 hours, the averaged nitrate nitrogen removal rateare 86.31%, 86.79% and 86.48% respectively, while the total nitrogen removal rate are 87.01%,89.89% and 87.48%.

Under the condition of enough carbon sources, the nitrate nitrogen and total nitrogen removal rate of these three tanks show no obvious difference. It showed that the supplement of carbon source is the key technique to remove the nitrate nitrogen in poor biodegradability water, and

increasing biomass and changing the way of denitrification only had no significant effect on denitrification.

Aquatic plant selection

In practical project, the supplement carbon source by adding glucose will increase the cost of project construction, and also have the shortage such as man-made factors in operations management. Breeding some aquatic plants to release TOC plentifully can not only solve carbon source problem, but also provide the good landscape value. The plants themselves can absorb some nitrogen and phosphorus nutrients through root system which is the effective way for ecological engineering to supplement carbon sources.

The organic matters secreted from aquatic plant roots are low molecular organic compounds, Polymer adhesive material, cells or tissue loss material lysate and so on, in which, the low molecular weight sugars, organic acids, amino acids and phenolic compounds in the Low molecular organic compounds, can mostly become the carbon sources for denitrification. According to the climate characteristics in Beijing, the experiment chooses four kinds of plants whose root system are well-developed called Eichhornia crassipes, Agavaceea, Isolepis cernua, and Spathiphyllum floribundum to breed suitable aquatic plant.

The aquatic plant mentioned above are cultivated in the 10L incubators respectively with a blank group, and the TOC concentrations are inspected every day. Results of the experiment indicated that the TOC secreted by Agavaceea is highest, which increaseds 1.3223mg/L comparing with the blank group; the Isolepis cernua took the second place, which increases 0.9431mg/L; the Eichhornia crassipes and Spathiphyllum floribundum are relatively weak, which Increases only 0.4940 mg/L and 0.4452 mg/L respectively, ss shown in Figure 6. Additionally, in Section 3.1,the above aquatic plants are planted in the tank II showing that the Nitrate removal efficiency improved significantly, and it proved that the Isolepis cernua and Agavaceea are the selected aquatic plants with good performance of supplementing carbon source.

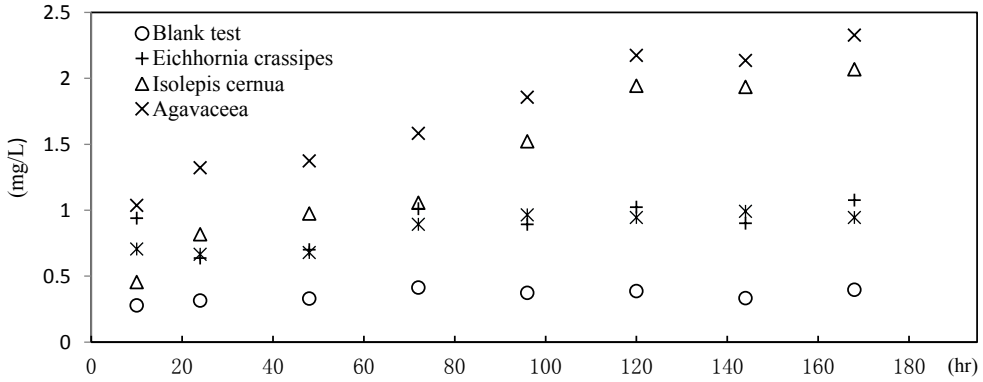


Figure 6. Curves of TOC secreted from aquatic plant roots

Conclusion

In the ecological projectas for water purification of urban rivers which are mainly discharged by sewage treatment plants, the denitrification technology of low C/N iwater is the main way to eliminate the nitrate nitrogen. The experiment shows that the denitrification in poor biodegradability water is weak, and reinforced technology can achieve the goal of further water purification. The research get the following conclusion:

The structural design of ecological groove proposed in this research can form aerobic and anaerobic reaction site which provides favorable spatial condition for denitrification.

Through the comparison of adscititious biological materials and the blank group, we find that the denitrification effects are not significant. Therefore, the microbial biomass in the blank group of the system is sufficient, and the method to cultivate the sludge taken in the experiment is effective.

The denitrification effect is optimal when adding carbon source and C/N equals 4. The removal rate of NO3-N and TN all reach more than 87%. Therefore, we can consider that the supplement of carbon sources is the key technique to strengthen denitrification in urban river.

The quantity of TOC secreted by Agavaceea and Isolepis cernua is the highest, and they are aquatic plants with good performance of supplementing carbon sources which improve the denitrification remarkably in the experiments.

According to the researches of the some experts, the process of sulfur autotrophic denitrification needs no organic carbon source. The water quality from the tank II should be better and more stable, while it is not shown obviously in those studies, and it needs further study to test environment conditions and influential factors afterwards.

Keywords: rolling motion, chaotic series, phase space reconstruction (PSR), coupling multivariate, natural circulation (NC)

Abstract. The paper has established a combinatorial prediction model of chaotic time series based on history data and coupling data. Through the study of the flow characteristic about natural circulation under rolling motion, the single variable reconstruction and coupling multivariate reconstruction are discussed for chaotic time series based on phase space reconstruction technique, and the combinatorial prediction model has been built which bases on developing trend of history data and coupling relationship of correlative data. The paper also studied an example of coolant volume flow prediction with a relative precision of 0.9804 with the established model. The result indicated that the model with high precision and robustness could apply for natural circulation coolant volume flow prediction under rolling motion.

Introduction

Nuclear power plant may encounter additional transient outside force at any moment, for the complicated and changeful ocean condition. While the outside force cannot be ignored, the unstable status with high degree will occur in reactor systems. For instance, if the environment gives reactor system an additional swing force under the status of NC, a rolling acceleration will appear because of the small flow and outside force which cannot be neglected, which will drive or cumber the flowage of reactor coolant, affect the pressure drop distribution of systems, strengthen the coupling among the system elements, result in the fluctuation of coolant volume flow and reactor power, and lead to the emergence of obvious nonlinear characteristic phenomena[1,2] such as chaos oscillation, wave oscillation superposition. If the NC coolant volume could be forecasted by correlative data under rolling motion condition, manipulator could intervene in time and avoid accident when the flow is exceptional, and could judge the status of accident and make corresponding decision-making by the prediction result when the accident has occurred[3,5]. Therefore, prediction and analysis of corresponding parameter, which is under NC rolling condition, could make us find out the rule of unstable flow, provide a certain degree of help for judging the status of reactor systems for manipulator, and provide data support for nuclear power equipment in security.

This paper introduces the combinatorial prediction method based on history data and coupling data into predicting NC coolant volume flow, and the result indicates that this method could receive excellent effect on chaotic series prediction of NC under rolling condition.

Combinatorial prediction Model based on history data and coupling data

Chaotic time series combinatorial prediction means confirming the relationship between the past and the future on sequence axis by several methods with different principle, which is described by a series of parameters. This method could establish parameter model from the past to the future according to the existing data, and obtain the future development trend of chaotic series. The prediction principle of the method is shown in the figure 1 below:

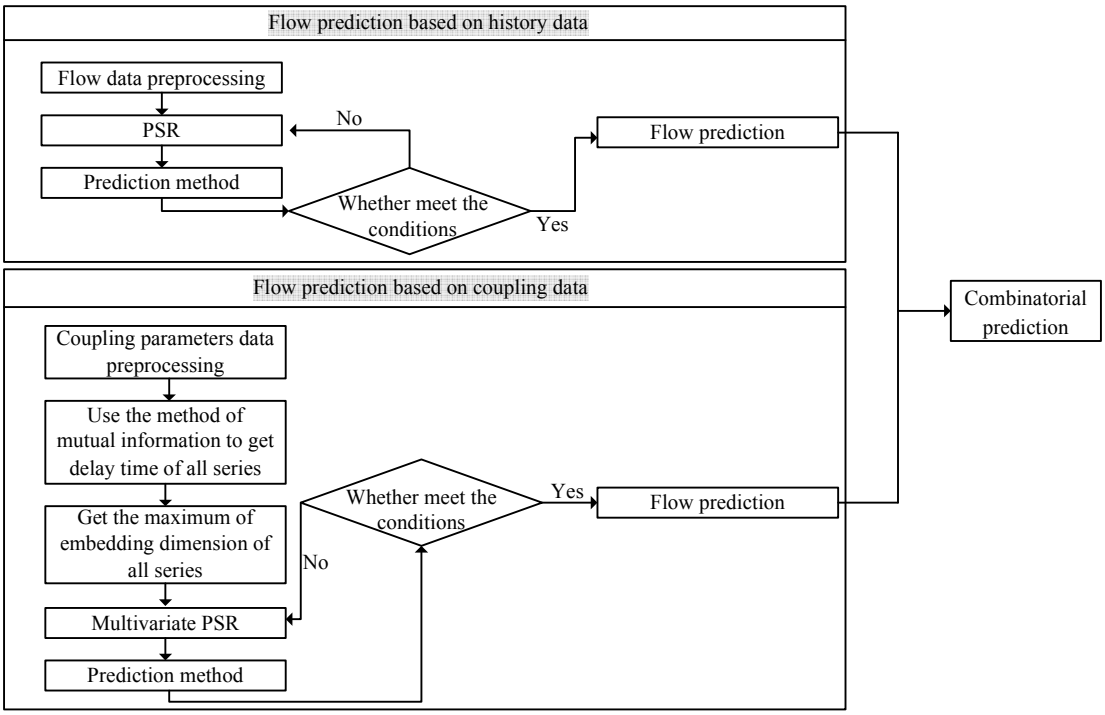

Fig. 1 Prediction principle figure of chaotic series

From the Fig. 1, no matter the single variable prediction based on history data (method 1) or multivariable prediction based on the coupling data (method 2), the key is PSR which needs to get the optimal embedding dimension and the best delay time of the corresponding variables. In the method 1, we adopt the idea of minimum prediction error for unified solution in order to get the optimal embedding dimension and delay time. However, in the actual situation, a system often shows dynamic evolution behavior and multi-level structure. So the number of coupling variable will be large. For this reason, the unified solution should not be used in method 2, otherwise the calculation could not run due to the large number of iterations. First, this paper uses the method of mutual information to get the delay time of coupling variables, and then changes embedding dimension of each series from 1 to the maximum, gets the optimal embedding dimension based on the principle of minimum prediction error.

Experiment and study

The experimental process as follows. The method 1 is described in [6].

Method 2: Step 1: set the initial condition and preprocess the data. Set the maximum of iteration to 50, decompose the coupling series with wavedec function, reduce the noise with ddencmp and wdencmp function, which could filter out the high frequency noise signal and keep low frequency information, and then normalize the data which have been reduced the noise.

Step 2: get the corresponding optimal $\tau_i (i = 1, 2, ..., K)$ using mutual information method for each of the above coupling variables, get the biggest embedding dimension $m_{\max i} (i = 1, 2, ..., K)$ by the method of false nearest neighbors, and reconstruct the phase space for these K variables.

Step 3: reconstruct the phase space based on the multivariate PSR theory, whose process is as follows:

Provided the NC flow time series expression is:

$$V = (y_1^0, y_2^0, \cdots, y_n^0) \tag{1}$$

Where the best embedding dimension and delay time are calculated by method 1, which are recorded as m_0, τ_0.

Provided the time series expression of coupling variables is Y, after reconstructing the phase space, we could get that:

$$\begin{aligned} Y_i = (&y_i^1, y_{i-\tau_1}^1, \cdots, y_{i-(m_1-1)\tau_1}^1, \\ &y_i^2, y_{i-\tau_2}^2, \cdots, y_{i-(m_2-1)\tau_2}^2, \\ &\cdots \\ &y_i^K, y_{i-\tau_K}^K, \cdots, y_{i-(m_K-1)\tau_K}^K) \end{aligned} \tag{2}$$

Where $m_j (j = 1,2,\cdots,K)$ is the value which is selected between 1 to maximal embedding dimension, $\tau_j (j = 1,2,\cdots,K)$ is the best delay time, $i = J_0, J_0+1, \cdots, N$, $J_0 = \max_{0 \le j \le K}((m_j - 1)\tau_j)$. Obtain the sample form for k-steps prediction of vector learning based on the method of Multivariate PSR:

$$\begin{aligned} Y_{train} = \begin{bmatrix} y_{J_0}^1 & y_{J_0-\tau_1}^1 & \cdots & y_{J_0-(m_1-1)\tau_1}^1 & y_{J_0}^2 & y_{J_0-\tau_2}^2 & \cdots & y_{J_0-(m_2-1)\tau_2}^2 \\ y_{J_0+1}^1 & y_{J_0+1-\tau_1}^1 & \cdots & y_{J_0+1-(m_1-1)\tau_1}^1 & y_{J_0+1}^2 & y_{J_0+1-\tau_2}^2 & \cdots & y_{J_0+1-(m_2-1)\tau_2}^2 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ y_{N-k}^1 & y_{N-k-\tau_1}^1 & \cdots & y_{N-k-(m_1-1)\tau_1}^1 & y_{N-k}^2 & y_{N-k-\tau_2}^2 & \cdots & y_{N-k-(m_2-1)\tau_2}^2 \end{bmatrix} \\ \begin{bmatrix} \cdots & y_{J_0}^K & y_{J_0-\tau_K}^K & \cdots & y_{J_0-(m_K-1)\tau_K}^K \\ \cdots & y_{J_0+1}^K & y_{J_0+1-\tau_K}^K & \cdots & y_{J_0+1-(m_K-1)\tau_K}^K \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \cdots & y_{N-k}^K & y_{N-k-\tau_K}^K & \cdots & y_{N-k-(m_K-1)\tau_K}^K \end{bmatrix} \end{aligned} \tag{3}$$

$$V_{train} = \begin{bmatrix} y_{J_0+k}^0 & y_{J_0+k-\tau_0}^0 & \cdots & y_{J_0+k-(m_0-1)\tau_0}^0 \\ y_{J_0+1+k}^0 & y_{J_0+1+k-\tau_0}^0 & \cdots & y_{J_0+1+k-(m_0-1)\tau_0}^0 \\ \vdots & \vdots & \vdots & \vdots \\ y_N^0 & y_{N-\tau_0}^0 & \cdots & y_{N-(m_0-1)\tau_0}^0 \end{bmatrix}$$

Step 4: train the Elman neural network by the sample form of vector learning which has been identified in Step 3, predict the flow by the Elman neural network model, and get the mean square error between prediction values and observation values.

Step 5: judge whether iteration is completed, if completed, turn to Step 7, otherwise, turn to Step 6.

Step 6: the number of iteration add 1, and then turn to Step 3.

Step 7: calculate the minimum mean square error of all the iterations, and get the best $m_i, \tau_i (i = 1,2,\cdots,K)$.

Step 8: take out the test data, and predict the flow using the best $m_i, \tau_i (i = 1,2,\cdots,K)$ and the Elman neural network model which has been established.

Combinatorial prediction:

Step 1: Provided that the predicted time series by method 1 is Y_1, the predicted time series by method 2 is V_1, the corresponding observed time series is O, the equation is established as follows:

$$aY_1 + bV_1 = O \tag{4}$$

Eq. (4) is written in vector form:

$$(Y_1, V_1)\begin{pmatrix} a \\ b \end{pmatrix} = O \tag{5}$$

If $A = (Y_1, V_1)$, the combination coefficients $(^{a,b})$ can be calculated by the least square method:

$$\begin{pmatrix} a \\ b \end{pmatrix} = (A^T A)^{-1} A^T O \tag{6}$$

Step 2: the flow is combinatorial predicted by using m_0, τ_0 which is confirmed by method 1, $m_i, \tau_i (i = 1, 2, \cdots, K)$ which is confirmed by method 2, and the combination coefficients a, b.

The relative accuracy formula is defined as follows:

$$E = \frac{\frac{1}{n_1}\sum_{i=1}^{n_1}(y_i - \bar{y}) \times (y_i^* - \overline{y^*})}{\sigma \times \sigma^*} \tag{7}$$

Where y_i , y_i^* respectively means prediction value and observation value of i th position; $\bar{y}$, $\overline{y^*}$ respectively means the corresponding average value for y_i, y_i^*; σ, σ^* respectively means the corresponding mean square error for y_i, y_i^*. n_1 means the number of prediction value. After calculating, the relative accuracy of figure 4a is 0.9713, figure 4b is 0.9507, figure 4c is 0.9712, figure 4d is 0.9804. The result has shown that the combinatorial prediction method has higher relative precision and more perfect prediction effect.

Conclusion

For the autocorrelation, nonlinear, and high coupling of marine reactor NC under rolling condition, this paper has suggested a combinatorial prediction algorithm based on history data and coupling data, which started from the PSR theory, discussed the single variable prediction based on history data and multivariate prediction based on coupling data, and considered the special circumstances, any of them failed, and formed combinatorial algorithm which has passed through the linear weighted processing. In order to verify the effectiveness of the algorithm, this paper took the coolant volume flow as an example, and the result has shown that the model could be used for NC coolant volume flow prediction under the rolling condition, and could satisfy the actual engineering requirements with high precision, small relative error and high robustness.

Keywords: fluorescence spectrometry; ^{40}K; radioactive concentration

Abstract. The pressed powder sample was determined by Epsilon 5 high-energy polarized energy dispersive X-ray fluorescence (EDXRF) spectrometer. The correlation coefficient of the standard curve method is 0.991 0. The precision is 2.98% and the relative deviation of the measurement standard samples is up to 6.40%, which showed that the precision and accuracy of the method were also good. Simultaneous measurement of seven soil samples with this method and γ-spectrometer were carried, the results of two analytical methods was compared using a paired t-test by SPSS program, which showed that there was no significant difference in the two sets of data. The results predicated that EDXRF could be a potential simple method for analyzing ^{40}K in soil samples.

Introduction

Radioactive concentration of ^{40}K in soil was measured usually by the gamma spectrometry. The method is accurate, but the measuring time of environmental samples by this usually takes more than 30000 s. X ray fluorescence spectrometer is X ray irradiated samples produced by the excitation light source. Emitting sample elements in different energy (discrete) X ray fluorescence characterization of these elements, by measuring the radiation energy emitted by the sample to know qualitative element, the knowledge content elements through the energy intensity, or quantitative. Previous fluorescence spectrometer was used for elemental content. Because natural radionuclides in the soil environment can be converted from corresponding, single element determination in environmental samples by X ray fluorescence spectrometer by the abundance ratio, half-life etal. Then the sample can only measure 600s enough. Therefore, in this work the X ray fluorescence spectrum measurement of K elements in soil will be converted into radioactive concentration of ^{40}K, and the spectrum comparison of measurement results with high purity germanium gamma ray, the reliability of X ray fluorescence spectrum measuring element content in soil samples.

The experimental part

The main instrument and device. Epsilon 5 high-energy polarized EDXRF spectroscopy: equipped with the highest excitation voltage of 100 kV, the maximum power of 600 W side beryllium window (thickness of 300 μ m) gadolinium anode X ray tube, PAN-32 germanium detector, active area of crystal is 300mm^2, thickness of 5 mm, the energy resolution ≤ 140 eV (2000cps Mn K_α), effective energy detection range of 0.7 ~ 100 keV, the maximum count rate can reach 2 × 10^5/s; 15 of two target (Mg, Al, Si, Ti, CaF_2, Fe, Zn, Br, Zr, Mo, Ag, CsI, CeO_2, Ge and Al_2O_3) ； 5 filters (Mo 250 μm , Zr 125 μ m, Cu 100 μ m, Al 500 μ m, Al 100 μ m): a family company: original Philips analysis instrument

Sample preparation. Take 6 g soil samples, soil samples were collected in Beijing surrounding natural soil samples or soil standard samples (GSS-1, GSS-2, GSS-3, GSS-4, GSS-5, GSS-6, GSS-7, GSS-8, GSS-9, GSS-10, GSS-11, GSS-12, GSS-13, GSS-14, GSS-15, GSD09, GSD10, GSD12, GSD 13, GSD14, GSD 01A standards) bought from China Exploration Institute of Geological

Sciences of geophysical and geochemical,then add 7 g of boracic acid as the lining, pressure of 35 t, of 10 s, the preparation of a outside diameter of 40 mm, the 33 mm in inside diameter[1].

Measurement method. Soil tablet in the EDXRF spectrometer, using CaF_2 to do the two target. Tube voltage was 25 kV. Tube current was 24 mA, 250 s measurements[2-4].

Correction of matrix effect and spectral overlap interference. Correction of matrix effect in this method using empirical coefficient and Compton scattering method, at the same time, particle size and mineralogical effect also made some correction, the mathematical formula [2 ~ 5]:

$$C_i = D_i - \sum L_{im} Z_m + E_i R_i \left(1 + \sum_{i=1}^{n} \alpha_{ij} Z_j \right) \quad (1)$$

In formula (1): Ci for unknown sample analysis of the content of element I; Di analysis calibration curve intercept of I; L_{im} interference element M on line analysis of elements I overlap interference correction factor; Z_m interference elements m content or count rate; E_i for the oblique rate analysis element I calibration curve the R_i analysis of elements; count rate of I (intensity ratio or with the internal standard); Z_j coexisting elements J content or the counting rate; n is the number of coexisting elements; alpha for matrix effect correction factor; I, J and m were analyzed for elements, coexisting elements and interference elements.

This method uses a plurality of calibration sample by equation (1) regression for the matrix effect and spectral overlap interference correction[6].

Results and discussion

Method detection limit. The detection limit is related to the substrate of the sample. Different samples because of its components and the content, scattering background intensity, spectral overlap interference degree and analysis of elements of different sensitivity, detection limits are changed. And the detection limit of each component in the sample is different, usually according to the formula (2) for calculating the detection limit.

$$L_D = \frac{3}{S} \sqrt{\frac{R_b}{t_b}} \quad (2)$$

In foumula (2): S for the analysis of elements in the sensitivity of [s^{-1} • Mg^{-1} • kg]; R_b as the background count rate; t_b for measuring the time background (s).

The method was used to measure the 50 soil samples. According to equation (2) the detection limit of elements K concentration were calculated. The average value is 10.7 mg/kg, which converted into radioactive concentration detection limit was 0.33 Bq/kg.

K (oxide) standard curve. The measuring results of the 21 standards are listed in table 1. Table 1 data of the regression analysis, K (oxide) measurement standard curve, the result is shown in figure 1. Fig. 1 the correlation coefficient of standard curve is 0.9910, a good linear relationship.

Table 1 Soil standard samples of K (oxide) concentration measurement results

Sample Name	Measured Value/%(n=10)	Sample Name	Measured Value/%(n=10)
GSS-1	2.65±0.04	GSS-12	2.628±0.03

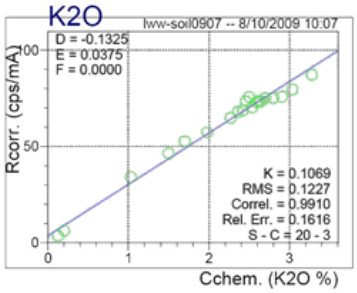

Fig.1. The standard curve of K_2O

Note: C_{chem} (K_2O%) as a percentage o, R_{corr} fluorescence intensity of potassium oxide.

Precision. 10 samples of GSD-11 soil standard samples was measured by X ray fluorescence spectrum (oxide) content. Measurement values are: 3.01%, 3.22%, 3.05%, 3.14%, 3.08%, 3.02%, 3.11%, 3.03%, 3.29% and 3.05%, and the average value is 3.10%. The standard deviation is 0.09%, The relative standard deviation is 2.98%. $\bar{x} \pm s = 3.10 \pm 0.09\%$,. The method is accurate.

Accuracy. The 2 standard GSS-16, GSD-11 are tested. The measurement results are given in table 2. As can be seen from table2, the maximum relative deviation from the reference values is 6.4%.The accuracy of the method is better.

Table 2 Standard sample measurement results and comparison reference value

Sample name	Measured Value /%	Reference valve/%	Relative deviation/%
GSS-16	2.66	2.50	6.4
GSD-11	3.11	3.28	5.2

Comparison of measurement results of energy dispersive fluorescence spectrometer and gamma spectra. By Formula (3) K_2O concentration in the sample will be converted into ^{40}K radioactive concentration[10]. $C_{K\text{-}40}$ (Bq/kg) for sample ^{40}K radioactive concentration (Bq/kg); C_{K_2O} (%) as the concentration of sample K_2O (%); 0.71 for the content of K in K_2O; 31.2 according to ^{40}K abundance, half-life calculated from the quality (g) converted into activity (Bq) coefficient.

$$C_{K-40}(Bq/kg) = C_{K_2O}(\%) \times 0.71 \times 10 \times 31.2 \quad (3)$$

Using this method and gamma spectrometer measurement of 7 soil samples. The results are listed in table 3.

Table 3 comparison of 7 soil samples from energy dispersive fluorescence spectrometer and gamma spectrometer measurement results

Sample number	^{40}K radioactive concentration /(Bq·kg^{-1})	
	Fluorescence spectrometer	Gamma spectrometer
201004S039	652	674
201004S002	568	477
201004S004	665	546
201004S007	671	702
201004S008	708	574
201004S011	668	671
201004S010	655	562

To compare in table 3 the 7 soil samples from energy dispersive fluorescence spectrometer and gamma spectrometer measurement results , paired t test was used . Probability of P calculated by SPSS program is 0.087, more than 0.05 significant level, showing that there was no significant difference between two groups of data, and the measurements are consistent. That is ,the ^{40}K content in soil can be measured by energy dispersive fluorescence spectrometer.

The measurement results correction. Cd is the main interference causing to K determination. But the content of Cd in soil is low, 4 orders of magnitude lower than the potassium content, so the Cd on the K content has less interference. K content determination process mainly uses empirical coefficient method for correction of matrix effect.

Conclusion

Sample preparation with pressed powder pellet, X ray fluorescence spectrometer analysis method was used for concentration of ^{40}K radioactivity in soil. The accuracy and precision of this method are better. So it can be used for the analysis of environmental samples with ^{40}K radioactive concentration.

Keywords: Mercury (Hg), Content, Settling process, Jiaozhou bay.

Abstract. Being a close bay, vertical settling was the dominant transfer process of Hg Jiaozhou Bay. Based on the investigation data of mercury (Hg) in bottom waters in Jiaozhou bay in 1979 to 1985 (in absence of 1984), this paper tried to analysis both of the settling processes and settling mechanisms of Hg. Results showed that that Hg in Jiaozhou Bay was settling continually over year, therefore a continued accumulation of Hg contents in bottom waters appeared, especially in spring and summer. Sediments in sea bottom could be both of source and sink of pollutants, especially for persistence pollutants such as Hg. Based on the both of the settling processes and settling mechanisms, the improve of recycle rate and the emission reduction of Hg should be the major pollution control strategies in Jiaozhou Bay.

Introduction

Jiaozhou Bay is close bay located in south of Shandong Peninsula. Being surrounded by economic developed cities such as Qingdao, Jiaozhou and Jiaonan etc., this bay has long been suffering from various pollutants such as benzene hexachloride, petroleum hydrocarbon, and heavy metals, all of whose pollution levels had reach certain degrees [1-11]. Hg is one of the most critical environmental pollutants, with characteristics of high toxicity, bioaccumulation, and persistence, and has been widely used in chloral-alkaline industry, plastic industry, electronic industry, metallurgical industry etc. [12-13]. Previous studies showed that both of surface and bottom waters in Jiaozhou Bay were polluted by Hg [5, 8, 10].

Having in mind that water mass exchange capacity in such close bay is limited, and the pollution reduction should be more difficult once has been polluted, it is essential to understand the major transfer process of Hg. Based on the investigation data of mercury (Hg) in bottom waters in Jiaozhou bay in 1979 to 1985 (in absence of 1984), this paper tried to analysis the both of the settling processes and settling mechanisms of Hg, and to provide basis for pollution control of Hg.

Material and method

Study area. Jiaozhou Bay is located in the south of Shandong province (35°55′-36°18′ N, 120°04′-120°23′ E), with total area, average water depth and the width of bay mouth of 390 km^2, 7 m and 3 km, respectively (Fig. 1). The main rivers are Haibo Rriver, Licun Rriver, Baisha Rriver, Dagu Rriver, Yanghe Rriver, and Loushan Rriver, all of wich have seasonal hydrological features, and are transfer canals for pollutants into the bay [1- 3]. This bay is typically a closed bay, and is surrounded by economic developed cities such as Qingdao, Jiaozhou and Jiaonan etc.

Data source. The data was provided by North China Sea Environmental Monitoring Center. The measurement methods of Hg in water samples was follow by The Chinese National Specification for Marine Monitoring (1991) [14]. The survey as conducted in May, August and November 1979, July, August and October 1980, April, August and November 1981, April, June, July and October 1982, May, September and October 1983, and April, July and October 1985,

respectively. We defined April, May and June as spring, July, August and September as summer, and October, November and December as autumn, respectively.

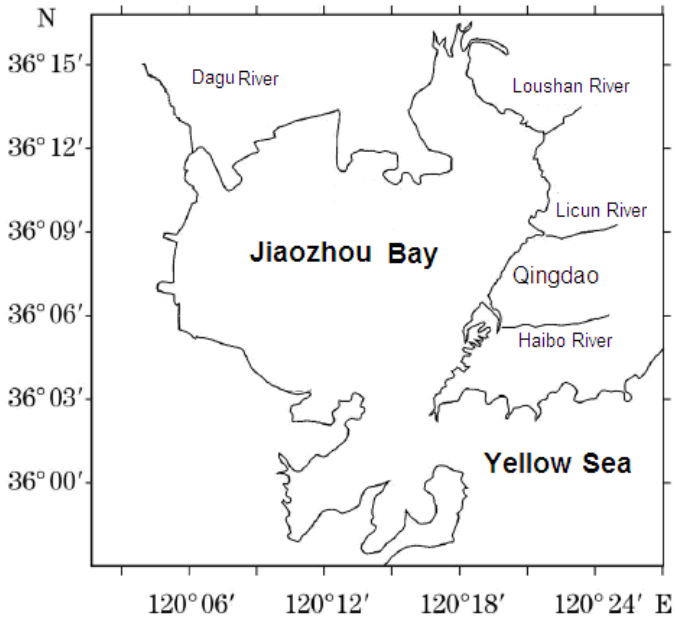

Fig. 1 Geographical location of Jiaozhou Bay

Results and discussion

Temporal variation. Hg is low-soluble, settlement is the major fate of Hg, particularly in this close bay. Hg is Jiaozhou Bay is mainly discharged from the major rivers. As the precipitation in this area is concentrated in spring and summer, the load of Hg in Jiaozhou Bay is relatively high in spring and summer. Meanwhile, due to the growth and reproduction of marine phytoplankton start in spring and reach the peak in summer, there are large amount of colloids in these periods, which have strong capacity to absorb Hg and settle to the sea bottom. For example, Hg contents in bottom waters in June, July, September, and October 1980 ranged from 0.002-0.007μg.L^{-1}, 0.002-0.021μg.L^{-1}, 0.005-0.029μg.L^{-1}, and 0.013-0.090μg.L^{-1}, respectively [8], while in April, July, and October 1982 ranged from 0.005-0.007μg.L^{-1}, 0.024-0.029μg.L^{-1}, and 0.020-0.032μg.L^{-1}, respectively. Another example, in spring and summer in1979, Hg contents in bottom waters were initially lower than in surface waters, while in autumn there was an opposite distribution [5]. The temporal variation of Hg contents in bottom waters indicated that Hg in Jiaozhou Bay was settling continually over year, therefore a continued accumulation of Hg contents in bottom waters appeared.

Spatial variation. In generally, Hg was firstly delivered to surface waters near the estuaries of the rivers, and then was transferred by means of horizontal diffusion and vertical settlement. Hence, the changes of Hg contents in bottom waters were coincide with in surface waters, and the high values were always occurred in spring and summer. For example, Hg contents in bottom waters in April, August, and November 1981 ranged from 0.029-3.125μg.L^{-1}, 0.002-0.026μg.L^{-1}, and 0.003-0.005μg.L^{-1}, respectively, while in surface waters ranged from 0.028-2.086μg.L^{-1}, 0.001-0.040μg.L^{-1}, and 0.002-0.017μg.L^{-1}, respectively [10]. Previous studies have showed the horizontal transfer processes of Hg in bottom waters [5, 10]. One of the most significant features was that there was low value zone in bottom waters in the bay mouth. For example, Hg contents in May 1983, April 1985, and October 1985 ranged from 0.010-0.017μg.L^{-1}, 0.025-0.075μg.L^{-1}, and 0.004-0.043μg.L^{-1}, respectively, which were much lower than in bottom waters in the estuaries and the inner of the bay. For a close bay like Jiaozhou Bay, the dominant transfer process was vertical settlement rather than horizontal diffusion. While for areas in the bay mouth, Hg in both surface waters and bottom waters could more easily be diffused by hydrological process.

Settling process. Based on the analysis above, it was clearly that vertical settling was the dominant transfer process of Hg Jiaozhou Bay. The settling processes of Hg in this bay are, 1) Hg is

firstly delivered to surface waters by stream flow, 2) Hg is transferred by means of horizontal diffusion and vertical settlement, and 3) the settling of Hg is happening continually over year, especially in spring and summer, therefore a continued accumulation of Hg contents in bottom waters appeared. The settling mechanisms of Hg in this bay could be induced as, 1) Hg is low-soluble and chemical stable, 2) large amount of colloids occur in spring and summer due to the growth and reproduction of marine phytoplankton, 3) the colloids have strong capacity to absorb Hg, and 4) Hg is absorbed to the colloids and settled to the sea bottom finally. These settling mechanisms are able to explain the settling processes, as well as the temporal and spatial variations of Hg in bottom waters in Jiaozhou Bay.

Summary

Based on the analysis of the temporal, vertical and horizontal variations of Hg contents in bottom waters, both of the settling processes and settling mechanisms of Hg in Jiaozhou Bay were revealed. As a close bay, vertical settling was the dominant transfer process of Hg Jiaozhou Bay, which was mainly occurred in spring and summer. Sediments in sea bottom could be both of source and sink of pollutants, especially for persistence pollutants such as Hg. Hence, the improvement of recycle rate and the emission reduction of Hg should be the major pollution control strategies in Jiaozhou Bay.

Keywords: Fuyu reservoir; Yangdachengzi reservoir; high definition; base-level cycles; framework; seismic

Abstract. In detailed study on sedimentary characteristics of Fu Yang reservoir around Threezhao area, based on the theory of high resolution sequence stratigraphy of the base level cycle isochronous contrast, regard short-term base-level cycle as the minimum isochronous contrast comparing unit, this paper has carried on the fine high-resolution isochronous contrast of the reservoir in the studied area, and the high resolution[1] sequence division of different orders of base-level cycle of Fuyu oil layer and Yangdachengzi oil layer. The Fuyu reservoir is divided into one complete long-term base-level cycle and three complete medium-term base-level cycle; while Yangdachengzi reservoir is divided into a long-term base-level rise hemicycles and 3 middle-term base-level rise hemicycles. According to mud logging, well logging and core analysis data, the sands group stratified mark of the Fuyu reservoir has been determined.

Identification for base level cycle of Fu Yang oil layer

There is a regional top marker bed boundary at the top of the Fuyu oil layer boundary. In the bottom of Qing one segment development 3 sets of oil shale, high resistance, high gamma, on the seismic profile of high continuity of strong amplitude reflection (T2); There is a tend to be stable distribution of mudstone at the bottom of the Fuyu oil layer, and low resistance, high gamma and high sound waves, can be used as a standard, corresponding to the seismic reflection (T2-1-1)(Fig 1~2).

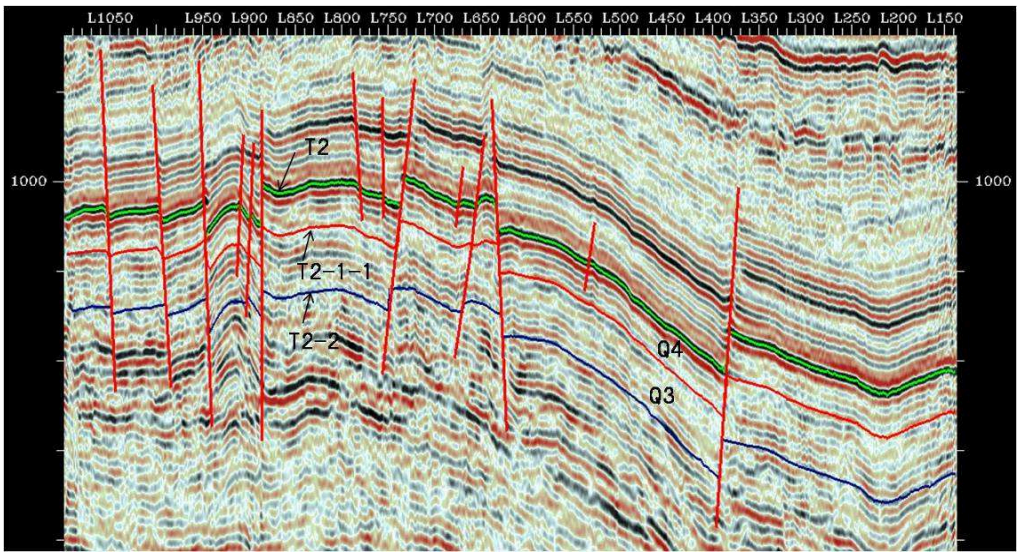

Fig 1 Threezhao peripheral zone seismic area is still home FU Yang reservoir top floor seismic response characteristics (Trace685)

Yangdachengzi reservoir bottom boundary is the fountain of the quan three segment of the bottom side that a regional unconformity surface[2]， mainly by early quan three segment of braided river scouring subjacent bed of quan two segment shore shallow lake intrafacies. On the seismic

section , quan two segment truncation and quan three segment onlap could be seen at Concave side. In the sunken the composite wave and wave system of interface are different. Corresponding to the T2-2 reflector Songliao basin

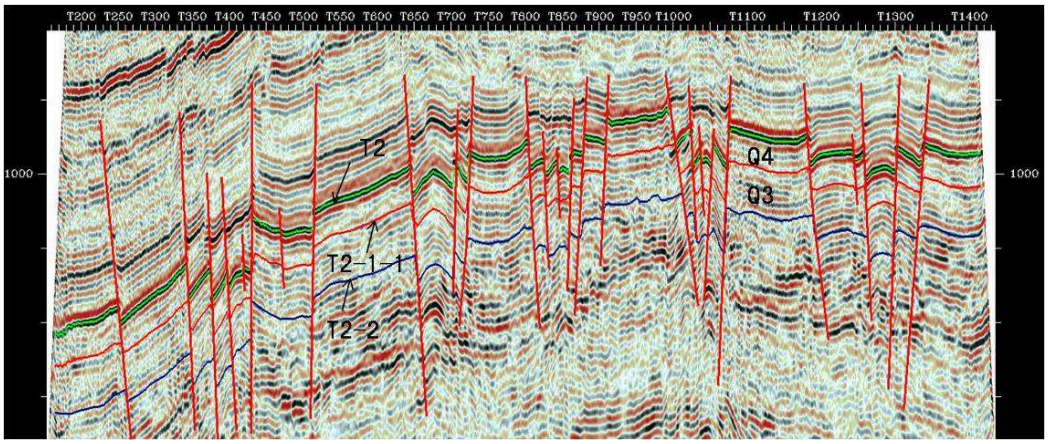

Fig 2 Threezhao peripheral zone on seismic area is still home FU Yang reservoir top floor seismic response characteristics (Line792)

The establishment of the isochronous stratigraphic framework

2.1 The sequence stratigraphic classification

(1)The division of Fuyu oil layer sequence:

Based on drilling in the study area of all levels of the recognition of base level cycle, Fuyu oil layer upon layer sequence is divided into: a complete long-term base level cycle and complete three medium-term base level cycle. A complete long-term base level cycle: F Ⅰ to rise half cycle, F Ⅱ +F Ⅲ to drop half cycle; 3 complete medium-term base level cycle: F Ⅰ F Ⅱ and F Ⅲ respectively a medium-term base level cycle, develop complete down half cycle and up half cycle.

F Ⅱ~F Ⅲ long-term base-level falling stage: F Ⅲ long-term datum rapid decline stage[3], development complete medium-term base level cycle, the datum plane down half cycle of the datum up half cycle of development; F Ⅱ reservoir group long-term datum slowly down to the lowest stage, also developed a complete medium-term cycle, datum down half cycle of the datum up half cycle of development.

(2)Yangdachengzi reservoir group sequence:

Based on drilling in the study area of the recognition of base level cycle, at all levels[4] could be divided into: Yangdachengzi oil layers of sequence 1 and half a rise in long-term base level cycle, three mid-term base-level rising half spiral swing back, Y Ⅰ, Y Ⅱ and Y Ⅲ respectively a medium-term base level rise half cycle.

Y Ⅰ~Y Ⅲ long-term base-level rising stage: the long-term base level[5] rising stage mainly experienced three stages: Y Ⅲ datum for a long time slowly rising - began to accelerate stage; Y Ⅱ long-term base level of accelerated phase; Y Ⅰ datum for a long time slowly rising stage. The thickness of the base level cycle as a whole has the characteristics of the first thickening and thinning. During the long-term base level rise, each set of the characteristics of sedimentary began to increase datum are falling, between groups have been developing wash surface of a boundary.

2.2The high resolution sequence stratigraphy framework is established in this paper

(1)Closure skeleton contrast section is established

This research article 19 and provenance direction nearly vertical frame transverse section and article 17 and provenance direction nearly parallel to the frame profile, overall understand three peripheral zone Fuyu reservoir origin and Yangdachengzi formation thickness of oil layer, lithofacies and sedimentary cycle variation characteristics. And Yangdachengzi Fuyu reservoir, building frame section 36, and optimizing drilling, logging and core information data is complete on

the four key Wells contrast, a sequence stratigraphic framework in order to establish the unified with the follow-up study of sedimentary facies interpretation and validation profile .

(2)Closed profile high resolution sequence stratigraphic isochronous contrast at all levels

In this study, the skeleton section can be compared to the profile closed hierarchical control, classification comparison, classification of high resolution sequence stratigraphy in the form of fine isochronous contrast. By contrast, has established the skeleton section 36, 273 Wells completed in the stratigraphic correlation, Fuyu oil layer in the study area is established and Yangdachengzi reservoir of high resolution sequence stratigraphic isochronous framework.

Fuyu sequence stratigraphy distribution characteristics

We even the well profile is used to study the longitudinal vertical[5] distribution regularity of the sequence. Plane, according to research the thickness of each sequence statistics Wells in this area, we compiled the four level of sequence stratigraphic thickness contour map, shows that the planar distribution characteristics and evolution rules of the sequence.

(1) The east of Yu region F Ⅰ strata thickness

The rage of strata thickness for F Ⅰ is 60~100m, the strata thickness thinning gradually from southwest to northeast and the high value is distributed in the south.

(2) The east of Yu region F Ⅰ 1 formation thickness

The rage of strata thickness for F Ⅰ 1 is 11~41m, the strata thickness thinning gradually from southwest to northeast and the high value is distributed in the south

(3) The east of Yu region F Ⅰ 2 formation thickness

The rage of strata thickness for F Ⅰ 2 is 15~58m, The strata thickness thinning gradually from southeast to northwest and the high value area in the southeast, the low value distribution in the northeast.

(4) The east of Yu region F Ⅰ 3 formation thickness

The rage of strata thickness for F Ⅰ 3 is 17~59m, The strata thickness thinning gradually from southwest to northeast and The high value area in the northwest.

(5)The east of Yu region F Ⅱ strata thickness

The rage of strata thickness for F Ⅱ is 17~59m, the strata thickness thinning from southeast to northwest, the low value scattered in the northwest and the high value distributed in the southeast continuously.

(6) The east of Yu region F Ⅱ 1 formation thickness

The rage of strata thickness for F Ⅱ 1 is 18~42m, Strata thickness thinning from southeast to northwest and the low value scattered in the north, the high value are mainly distributed in the south.

(7) The east of Yu region F Ⅱ 2 formation thickness

The rage of strata thickness for F Ⅱ 2 is 24~52m, Strata thickness thinning from the southeast to the northwest.The low distribution in the north and the high value are mainly distributed in the south.

(8)The east of Yu region F Ⅲ strata thickness

The rage of strata thickness for F Ⅲ is 24~80m, and the strata thickness thinning from southeast to northwest, the high value area are mainly distributed in the south and the low scattered in the north.

(9) The east of Yu region Y strata thickness

The rage of strata thickness forY is 210~356m, the strata thickness range of variation is large, the high value are mainly distributed in the southwest and low values are mainly distributed in the north.

(10)The east of Yu area isY Ⅰ strata thickness

The rage of strata thickness forY Ⅰ is 64~144m, the strata thickness range of variation is large, the high value are mainly distributed in the southwest and low values are mainly distributed in the north.

(11) The east of Yu region YⅡ strata thickness

The rage of strata thickness forYⅡ is 70~150m, the strata thickness thinning from southwest to northeast, the high value distribution in the southwest and the low are coverd in the northwest.

(12) The east of Yu region YⅢ strata thickness

The rage of strata thickness for YⅢ is 65~122m, the strata thickness thinning from southwest to northeast, the high value distribution in the southwest and the low value scattered distribution in the northeast.

The southwest of FuYang oil layer is very thin, then the northwest and southeast second and the northeast is the thinnest. The high value[6] area is located in the southwest.

Variation of the overall thickness of Fuyu oil layer is not obvious, the strata thickness thinning from southwest to northeast, so it has embodied sedimentary period of quan foru segment. The structure of the Threezhao surrounding area is stay in the uniform slow subsidence stage

The rage of strata thickness for Yangdachengzi YⅠoil layer is 90~110m, Variation of the overall thickness is not obvious, The southwest is thicker than the northeast more than ten meters slightly. The rage of strata thickness for YⅡ is 85~100m, the thickness that more than 100 m mainly locate in the Midwest of the study area. The rage of strata thickness for YⅢ is 100~150m and variation of the formation thickness is not obvious, the high value area is located in the central and nearly east-west distribution.

Conclusion

(1) Integrated application of seismic, logging, and core data, Fuyu oil layer upon layer sequence can be divided into: one complete long-term base level cycle and Complete three complete medium-term base level cycle — FⅠ is a medium-term base level cycle, FⅡis a drop half cycle that has develop completely and FⅢ is a Rise half cycle that has develop completely. The Yangdachengzi oil layer upon layer sequence can be divided into: one long-term datum rise half cycle and three mid-term base-level rising half cycle. They are all Mid-term base-level rising half cycle.

(2)The Yangdachengzi oil layer around the Threezhao region mainly develop fluvial facies, Source mainly comes from the north and northwest. Channel subfacies[7] is development in the plane. The scale of river channel is very large and distribute widely. Flow from the northwest to southeast, and give priority to with the channel sand , mudstone is given priority to with purple patches; The Yangdachengzi oil layer at the section mainly develop fluvial facies. The thin layer of delta plain and front subfacies is developed at the upper part of YⅠ. On the whole it is a process of retrogradation from YⅢ to YⅠ.

(3) The relation between oil and water around the Threezhao region is complex, The Fuyang oil layer mainly develop Oil water type, mixed type, pure oil type and more water type. The Fuyang oil layer at the plane mainly concentrate on the east of the studied area, large area connecting piece, Different regional profile has different characteristics in the plane. The southwest and the east of the oil layer are spread over FⅠ,YⅠand YⅡ; The northwest of the oil layer is spread over FⅠ,and the northeast is given priority to with water.

Use Horizontal Aeration Method to Treat Organic Pollution in Soil

Luyang Xu[1, a]

[1]Southwest Jiaotong University, Chengdu, Sichuan, China

[a]674306863@qq.com

Keywords: aerator pipe, horizontal, double level, vertical, microorganism, organic pollution

Abstract

This design adopts the method of horizontal arrangement to set the aerator pipes because it's more effective than an upright way. The pipes are divided into two vertical levels. Firstly there should be an excavation of foundation pit or grooves to put the pipes in two levels. Then the pipes in two levels can be set at vertical directions. After burying the pipe the earth should be backfilled into the grooves. When backfilling the lower level groove, we put some certain microorganism to help cleaning the organic pollution. While working, the pipes above are mainly used to manufacturing gas phase concentration difference, letting the organic volatilize and goes into the atmosphere. The pipes in lower level are mainly used to provide oxygen to microorganisms in the soil, so that they can decompose organic and make them into inorganic which is no harm to the soil and ground water.

Principle of an aeration technology

Aeration is a kind of technology using pump to inject fresh air to the saturated soil. Because organic pollutants concentration differs between gas and liquid, so they can get into gas through volatilization. Then due to aid of buoyancy, pollutants will rise with air gradually into the unsaturated zone [1]. That is when we can collect the pollutants by using certain equipment like SVE system to achieve the goal of eliminating organic pollution in soil and protect groundwater. At the same time, the air can provide sufficient oxygen to underground aerobic microorganisms, promoting organic pollutants' biodegradation.

This design adopts the method of horizontal arrangement with two levels. As the main purpose of the arrangement of bottom pipes are to provide oxygen, give them a small gas eruption rate and make the ones at the top erupt more air to create a better air distribution in soil. The arrangement is shown in Fig.1. The two pairs of green pipes are aeration pipes in two different levels and the red ones are collecting device SVE.

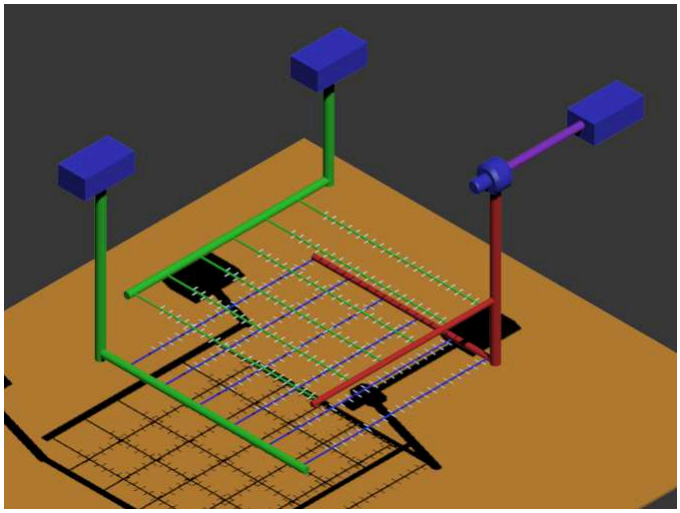

Fig.1.The arrangement of the whole device

Aeration is a kind of in-situ remediation which can reduce the pollutants exposure and disturbance to the environment of the largest degree. It has features like direct, fast, economic, effective and environmental protection which give it a good application prospect.

Device Settings

The lower level of aeration device:

Task of the pipes in this level is promoting biological activity of the microorganisms through the way of pumping air into the soil.

When arranging, firstly we should excavating grooves according to the density and length, drill a duct for the arrangement of main pipe. Set the pipes into the grooves and make sure they're connected with the main pipe for that level. Then mix the earth outside the groove with microorganisms and backfill the soil. This level of pipes should be set 4-5 meters under the surface of the ground. The main pipe should be long enough to reach out of the surface and be connected with air pumps.

The upper level of aeration device:

The upper level plays the most important role in this device. It uses pump to inject fresh air into the soil below water level through a horizontal well. Through a series of mass transfer process the pollutants in pores and groundwater will evaporate into the air. The air full of pollutants gradually rises under the pressure of buoyancy, keep carrying pollutants to the collect devices SVE. So there's a decrease of pollution rate in the soil and groundwater. When arranging, the grooves should be vertical to the pipes in the under level. It is for taking full use of air diffusing taper and space in the soil. The pipes' depth should be no more than 0.7m above the under pipes but no less than 3 meters below the ground surface. That's because there's a height needed for the rising and spread of the air. There also should be a main pipe which can attach all the pipes to an air pump. The details of the aeration pipes in two levels are shown in Fig.2. Between them the blue one is in the under level. And the red one is in upper level.

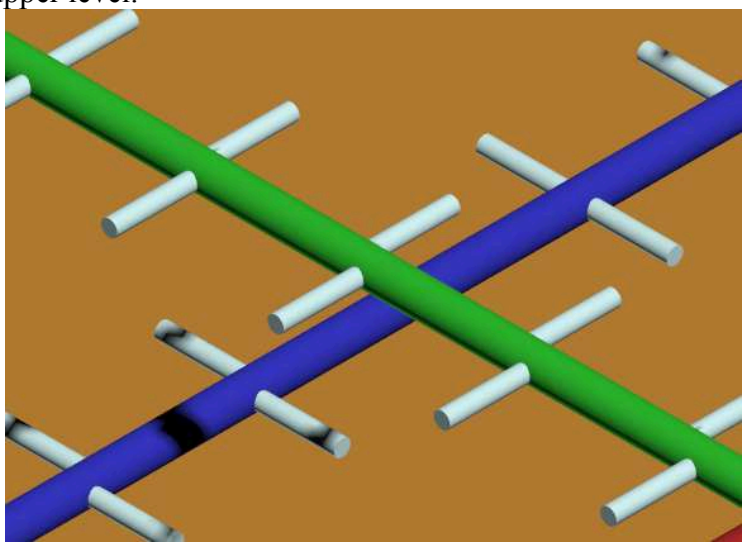

Fig.2. Details of upper and under aeration pipes

Comparison between traditional and horizontal aeration

In the traditional upright aeration method, the pipes are set vertical, when arrangement the pipes should be insert into the earth to a certain depth in order to make the shape of the flow a vertical ball distribution [2]. Because each aeration pipe has its own radius of influence, so it has to be a proper density of pipes to ensure the effect of the aeration. But due to the flow and diffuse features of the air the earth near the bottom has a very small area contact with air (Fig.3). So there must be a large density of pipes to let the under soil have a high aeration rate. And this will cause serious damage not only on the surface or inside the earth, but also effect mechanics and ecological feature

of the soil. It'll also cause a lot of overlap on upper soil aeration volume, which will be a huge waste of energy and sources. The schematic is Fig.4.

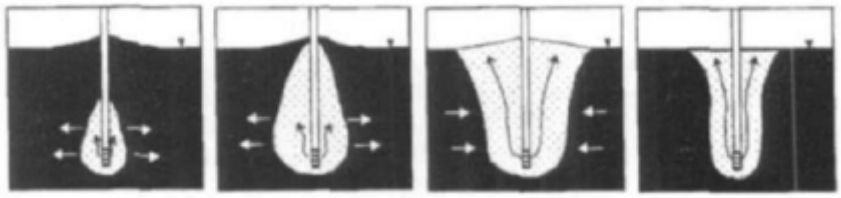

Fig.3.Gas cone of traditional upright aeration

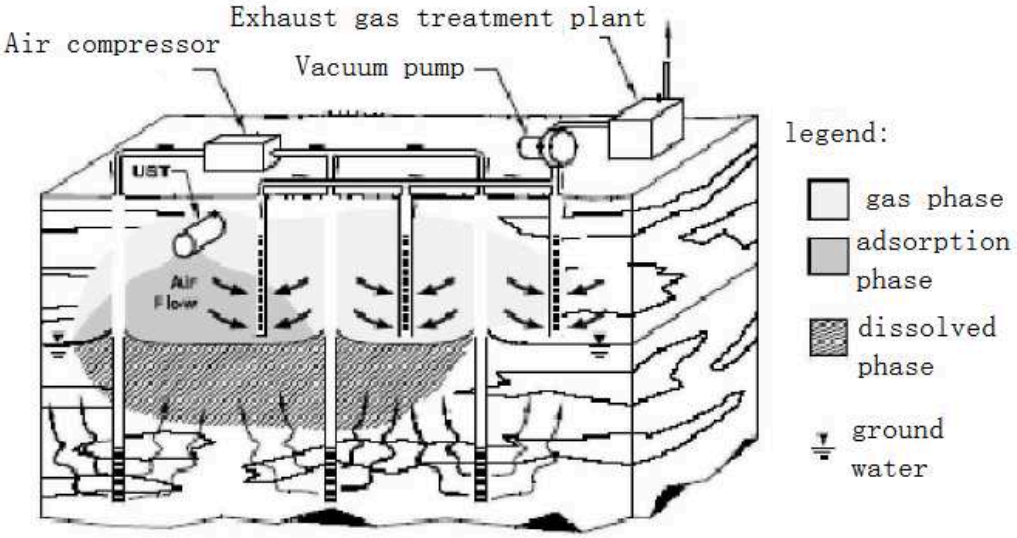

Fig.4. Schematic of traditional aeration pipes

In our device, the aeration pipes are multilayer horizontal arranging in X or cross mode. Gas input source is controlled by a main pipe separately each level, and ach main pipe is connected to one or a few pump machines. Though there will still be damage to the earth where the pipes lie. But contrast with the traditional way which will destroy the integrity of soil from the surface to bottom, the surface of the ground may still remain no harm by using horizontal way. Besides the bearing capacity of the whole area will hardly change. In the aspect of aeration efficiency, the insufficiency of aeration rate at the initial stage can be solved by coordinate the amounts of aeration pores on pipes and aeration rate. The control of direction and pores 'density will also reduce the gas being used and improve efficiency. [3]This avoids the huge consumption of energy. What's more by using horizontal mode can significantly improve the uniformity of airflow. [4] The schematic of gas cone is in Fig.4. The microorganisms can also help a lot on promoting the efficiency of tuning pollutants into inorganic. [5] The schematic of gas cone is in Fig.5.

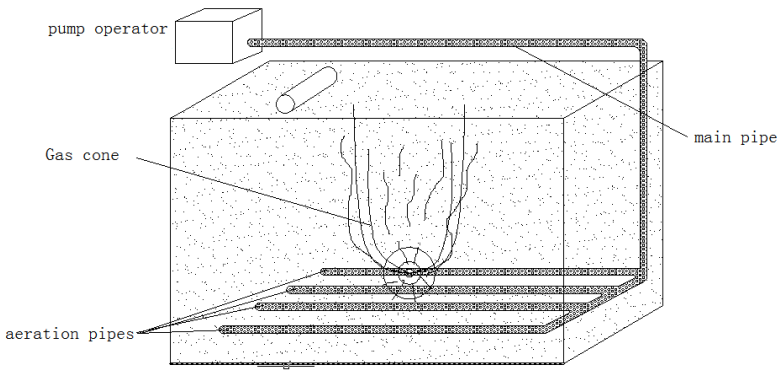

Fig.5.Gas cone of horizontal aeration pipe

Characteristics analysis

Advantages: The horizontal arrangement improves aeration efficiency especially at the initial stage. It can also improve the uniformity of airflow. Save energy, power and space while running a system like this. Microorganisms can help make up the missing efficiency where the airflow cannot pass through.

Disadvantages: Complex and a waste of manpower and money while excavating the grooves.

Conclusion

The double-leveled horizontal aeration device promotes the effecting range of gas cone, so it will improve the efficient of aeration.

The device rationalize the density of aeration pipes and direction of erupted gas so that it will save energy and.

The new device avoids destroying the earth on the surface and bearing capacity of the ground layer in the largest extent.

Keywords: Fructus Lycii; Mineral element; discriminant analysis; Identify

Abstract: In order to rapid discriminate the source of Fructus Lycii origin, Fructus Lycii from five different areas were collected, the content of K, Ca, Na, Mg, Fe, Zn ,Cu and Mn were analyzed with flame atomic absorption spectrometry，and the data was analyzed with Stepwise discriminant analysis method， and the discriminant function was established. The results showed that Fructus Lycii from five different areas was well clustering. The discriminant model was re-discriminated by using the method of mutual test; its discrimination accuracy was 94.4% for the original samples and the unknown samples. The recognition rates for Ningxia, Hebei, Qinghai cultivation regions were all 100%. In conclusion, mineral element combined with chemometrics method was a fast and accurate method to identify the origin source of Fructus Lycii.

Introduction

Lycium is a multi branched shrub plant of Solanaceae Lycium. It was distributed at home and abroad. Its fruit was said medlar, also called Gou screwdriver, wolfberry red. Mainly for the Ningxia wolfberry medicinal species. Modern pharmacological studies confirmed the fruit of Chinese wolfberry can adjust the immune function, can effectively inhibit the growth of tumor and cell mutation, can delay aging, anti fatty liver, regulating blood fat and blood sugar, and promote hematopoietic function and other aspects of the role.

Mineral elements in plant is closely related to the content and growth environment, the distribution of mineral elements in different habitats in the environment are different, and this difference can be reflected to the plants, so the content of mineral elements can be regarded as one of standard for plant origin discrimination[1-3]. Medlar contains many kinds of mineral elements, the quantity of mineral elements, in addition to physiological characteristics, is mainly concerned with the physical environment, the content of some elements in the different areas has many differences[4].

Instruments and Reagents

TAS- 990 atomic absorption spectrophotometer; analysis of the electronic balance; ultra pure water machine; SUNWAY- II ventilation cabinet; DB-2 stainless steel adjustable electric heating board; DZF- 6020 type vacuum drying box, K, Ca, Na, Mg, Fe, Mn, Zn, Cu hollow cathode lamp; glass instrument with 30% nitric acid soaking for 24 h, then using two DI water rinse clean.

Concentrated nitric acid (GR); $HClO_4$ (GR); K, Ca, Na, Mg, Fe, Mn, Cu and Zn standard solution (concentration was 100 μ $g \cdot mL^{-1}$, China metrology measurement Institute); cesium chloride; lanthanum oxide; the Chinese wolfberry source is shown in table 1.

Table 1 Origins of samples

Sample number	1	2	3	4	5
Origin	Hebei	Inner Mongolia	Xinjiang	Qinghai	Ningxia

Experimental Methods

The raw material drying at 60℃ for 4 h, crushing, 60 mesh sieving, each sample weighing 1g (accurate to 0.0001 g) test.

By wet digestion method, weigh the sample, put in 250 mL Erlenmeyer flask, add 25 mL of digestive juice (HNO_3:$HClO_4$=4:1) soaking for 24 h. Placing the electro thermal heating, removed it until a large white smoke disappeared, cooled to room temperature, diluted with ultrapure water, transferred to a 50 mL volumetric flask, constant volume, shake, stand-by. According to GB/T 18932.12-2002 'honey, sodium, calcium, magnesium, potassium, zinc, iron, copper, manganese, chromium, lead, cadmium content determination method of atomic absorption spectrometry', determined K, Na, Ca, Mg, Cu, Fe, Zn, Mn eight content elements in 8 different origins. Soil available and exchangeable elements are extracted using EDTA- ammonium acetate extraction [5] and DTPA extraction [6].

Results and Analysis

Analysis of mineral elements content in Chinese wolfberry in different regions

Results of the content of K, Na, Ca, Mg, Cu, Fe, Zn, Mn in different areas of medlar can be seen in table 2. From the measurement results, differences in content of Cu ,Fe , Zn, Na, Ca of the mineral elements in Chinese wolfberry in different regions is obvious, but the distribution of elements present regularly, all with K, Na, Ca, Mg high content, Cu, Fe, Zn, Mn low content.

Correlation analysis between the fruit of Chinese wolfberry and mineral elements in the soil

Significant correlation between mineral elements in Fructus Lycii ($P < 0.05$) or very significantly correlated ($P < 0.01$), suggesting that they have some synergistic effect on the absorption, was negatively correlated with Fe and Mg, Ca, Na, Fe and this showed that the absorption of several mineral elements may exist antagonism. No significant correlation between Mn and other elements (Table 3). Table 4 shows that, between soil medlar and its origin Zn, Mn, Mg, Ca, Cu, Na elements showed significantly or very significantly correlated.

Table 3 Correlation matrix of 8 mineral elements of Fructus Lycii

Discriminant analysis in Chinese wolfberry in different regions

To establish discriminant function discriminant analysis method of medlar mineral components of 8 variable stepwise discriminant analysis was performed using the Bayesian model, a sample data, every increase of one variable with the greatest effect on discrimination, the discriminant equation, and verify the identification rate. Stop introduced in the correct ratio of discrimination no longer increases, the establishment of mathematical model. Finally introducing the distinguishing function of 4 variables, excluding the 4 variables, finally got 4 canonical discriminant functions are as follows:

D1=1.773Cu+0.095Fe-1.011Zn+0.515Mn

D2=-0.352 Cu +0.849 Fe +0.796 Zn +0.373 Mn

D3=-0.071 Cu -0.640 Fe +0.527 Zn +0.866 Mn

D4=-0.325 Cu +0.131 Fe +1.022 Zn -0.515 Mn

The typical characteristics of D1, D2, D3, D4 discriminant function values were 25.909, 4.921, 1.506 and 0.062, respectively, can explain variance 80%, 15.2%.4.6% and 0.2%, the former two discriminant function can explain variance 95.2%, characteristics of 4 kinds of mineral elements into the equation can reflect all of Chinese wolfberry using discriminant function, the basic can distinguish the origin of Lycium barbarum. In order to unknown sample medlar discrimination, established 5 discriminant function, were used to describe the characteristics of the Chinese wolfberry mineral elements, discrimination is as follows:

M1=-363.089+35.927 Cu+0.521Fe-4.013Zn+8.469Mn
M2=-91.178+16.773 Cu+0.331Fe-1.732Zn+4.740Mn
M3=-106.683+18.420 Cu+0.116Fe-2.208Zn+5.449Mn
M4=-190.565+22.960 Cu+1.047Fe-2.239Zn+6.235Mn
M5=-138.502+17.374 Cu+0.651Fe-1.242Zn+6.434Mn

Table 4 Correlation matrix f 8 mineral elements between soil and Fructus Lycii

Soil \ Medlar	Cu	Fe	Mn	Zn	Ca	Mg	K	Na
Cu	.720*	.572	.199	.752*	.238	.080	.446	.456

Keywords: Tight sandstone formation; Porosity calculation; Permeability estimation; Core calibration log method.

Abstract Porosity and permeability are two important input parameters in formation evaluation. However, It faces a great challenge for formation porosity and permeability estimation in tight sandstone reservoirs in the Ordos basin of northwest China due to the greater contribution of rock matrix and complicated pore structure. In this paper, based on the analysis of conventional log responses and 324 core samples drilled from the target formations in different wells, the estimation models of reservoir porosity and permeability are established, and the reliability of these models are verified by comparing the calculated porosity and permeability by using the established models with core analyzed results. The absolute errors between these two kinds of porosities are all lower than 0.64%, and the relative errors between them are lower than 7.1%, these are coincided with the requirement of reserve estimation.

Introduction

Porosity are permeability are two important input parameters in reservoir evaluation and reserve estimation, especially for the permeability, it is connected with formation reserves, and it is also worth considering in the development program formulation (Mao et al. 2013; Xiao et al. 2014). To obtain these two parameters, plenty of methods had been proposed (Tiab et al. 1993; Biniwale et al. 2004; Xiao et al. 2009), such as the hydraulic flow unit (HFU) approach and classification scale models (CSM). However, there is not a universal model is proposed at present, especially for tight sandstone reservoirs, the contribution of rock matrix is important, and the pore structure is complicated. The statistical analysis method is always used. In this paper, using the core samples drilled from the target tight sandstones of Ordos basin in northwest China, the porosity and permeability estimation models are established.

Distribution of core porosity and permeability in the target tight sandstone

Figures 1 and **2** display the distributions of core porosity and permeability separately, from these two figures, we can observe that in our target formation, porosities range from 5.0 to 18.0%, and the average value is 9.9%. permeabilities range from 0.13 to 3.98 mD, and the average permeability is 0.58mD, belong to tight sandstone reservoirs.

Establishment of porosity and permeability estimation models

In our target tight sandstone formation, we obtain the conventional acoustic log, the density and neutron logs were not acquired due to the consideration of economy, and not nuclear magnetic resonance (NMR) log, which had been verified to be effective in tight sandstone porosity estimation, were also not acquired. Hence, we establish reservoir porosity and permeability estimation models based on the core calibration log method.

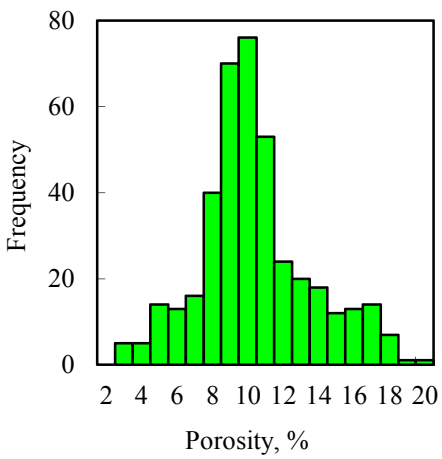

Fig. 1 Porosity distribution of the target formation in the Ordos basin of northwest China.

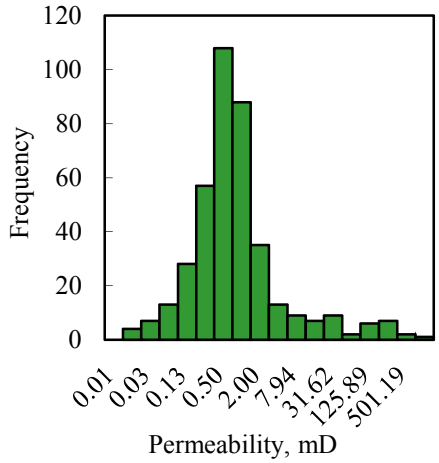

Fig. 2 Permeability distribution of the target formation in the Ordos basin of northwest China.

Preprocessing

Commonly, the procedure of data preprocessing, such as the depth shift, needed to be made to remove the additional errors before the evaluation models were established. In this study, we also made depth shift to make the core porosity match with the tendency of acoustic log. **Figure 3** shows the process of depth shift of core samples. From this figure, we can observe that after this well is preprocessed, the acoustic log curve match with core porosity very well.

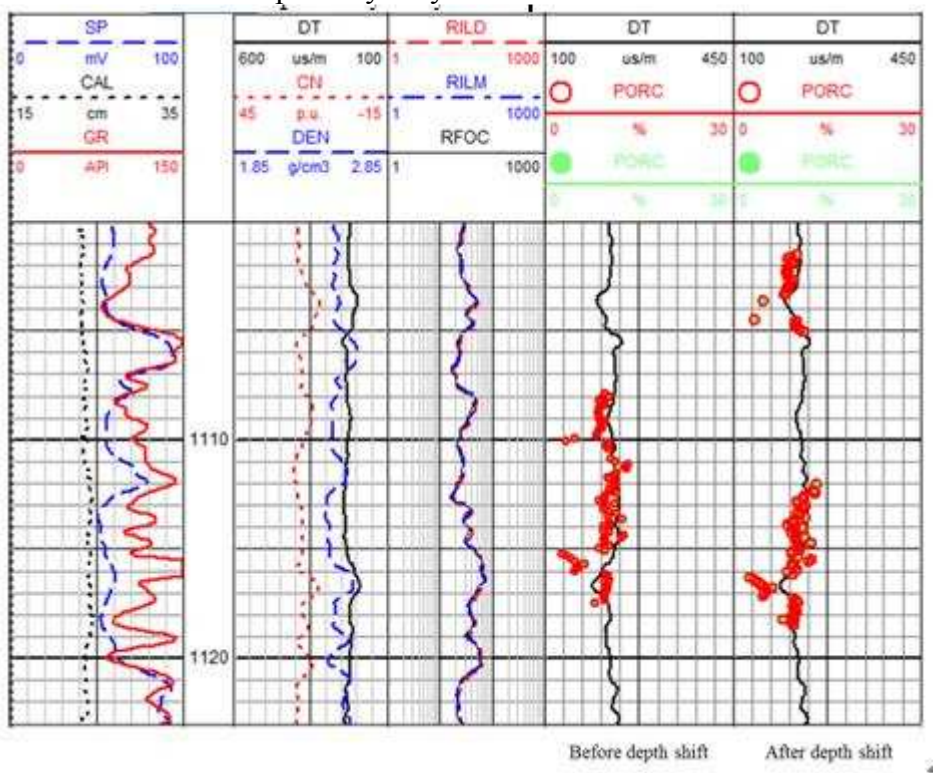

Fig. 3 The depth shift of core samples.

Establishment of porosity and permeability estimation models

After preprocessing, core porosity, permeability and the corresponding value of interval transit time are collected as the data set. The core calibration log method is used to establish the relationships of interval transit time (DT) vs. core porosity, core porosity vs. core permeability, and they are displayed in **Figures 4** and **5** separately. From these two figures, we can observe that good correlation exist between these three parameters; the correlation coefficients can reach to 0.83 and 0.84, respectively.

Hence, we can conclude that good relationships can be used to calculate porosity and permeability in the target tight sandstones.

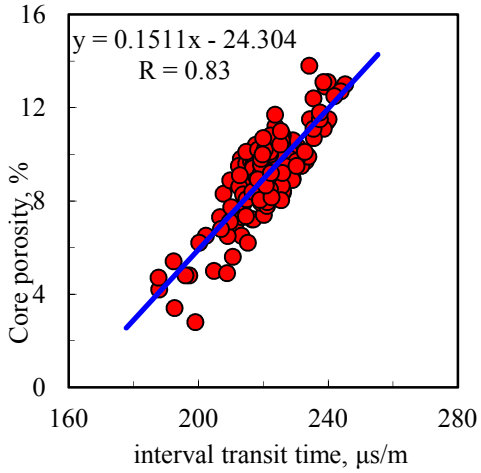

Fig. 4 Relationship of acoustic log and core porosity.

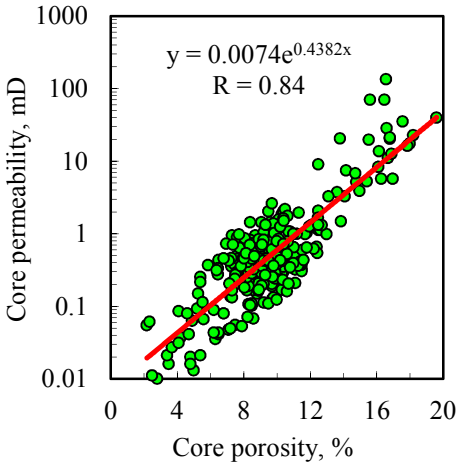

Fig. 5 Relationship of core porosity and permeability.

Case studied

By using the established models displayed in **Figs. 4** and **5**, several wells in the Ordos basin are processed, reservoir porosity and permeability are established, and they are compared with core analyzed porosity and permeability to verify the reliability of the established models. **Figure 6** shows a field example of comparing calculated porosity and permeability with core derived results. In the first track of **Fig. 6**, thedisplayed curves are gamma ray (GR), spontaneous potential (SP), and boreholediameter (CAL); their contribution is the formation indication. ILD displayed in the second track is the deep induction resistivity, ILM is the medium induction resistivity, and RFOC is the microspherically focused resistivity; .In the third track, we show the interval transit time log (AC), it is used for porosity estimation. POR_LOG displayed in the fourth track is calculated porosity by using model showed in **Fig. 4**, and PERM_LOG displayed in the fifth track is estimated permeability by using model showed in **Fig. 5**. Estimated porosity and permeability are compared with core analyzed results in these two tracks. From these two tracks, we can observe that the calculated porosity and permeability curves match with core derived results very well, this means that the established models are credible, thay can be used to calculate reservoir evaluation parameters in the Ordos basin.

To further verify the reliability of estimated porosity, the calculated porosities and the core analyzed results are listed in **table 1**. From table 1, we can observe that the calculated porosities and the core analyzed results are closed with each other, the absolute errors for all wells are lower than o.7%, and the relative errors are lower than 7.1%. these are coincided with the requirement of reserve estimation.

Summary

(1) No unified models can be established to calculate reservoir porosity and permeability, especially in tight sandstone reservoirs. The core calibration log method should be used to establish the corresponding models to calculate reservoir evaluation parameters in the target reservoirs.

(2) In the target tight sandstone reservoirs of Ordos basin in northwest China, good relationships between conventional acoustic log and core analyzed porosity, core analyzed porosity and permeability can be established. The established models are valuable in estimating reservoir evaluation parameters. The estimated results match with core analyzed results very well. They can be used for reservoir evaluation and reserves calculation.

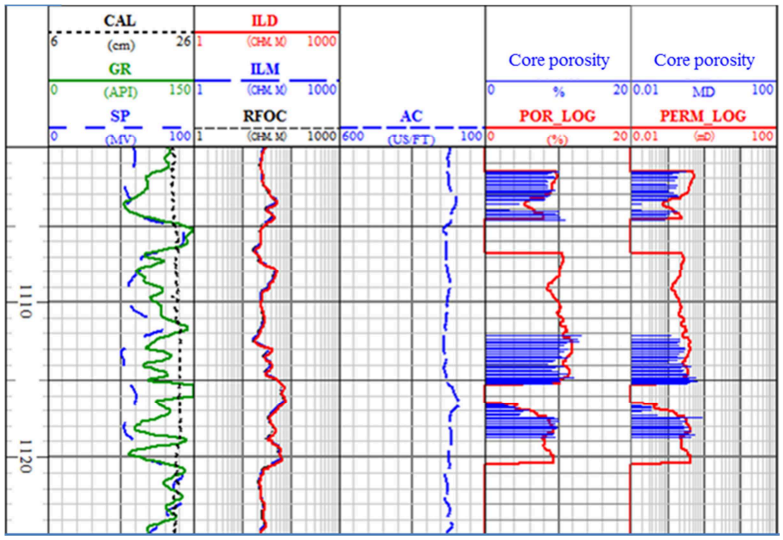

Fig. 6 Comparisons of porosities and permeabilities predicted by using the proposed models in the target tight sandstone reservoirs of Ordos Basin in northwest China.

Table 1 Comparison of porosities acqiured from different methods

Keywords: Huoyanshan tectonic belt; wellbore stability; Multiple collaborative; drilling fluid.

Abstract. In order to solve the downhole complex issues such as lost circulation, sticking and well collapse during drilling due to the development of coal-bed and coal seam, thick carbonaceous shale, formation is not homogeneous, the inclination is large, well-developed cracks and other reasons, which constraint exploration and development of oilfield in Huoyanshan tectonic belt region. According to the well instability mechanism of this block and the principle of "Materialized blocking, inhibiting surface hydration, effective stress support" multiple collaborative anti-sloughing drilling fluid, we developed a set of new drilling fluid systems suitable for the Huoyanshan tectonic plate through laboratory experiments. Field test application results show that the new drilling fluid system has a strong capability of salt resistance, anti-calcium and anti-poor soil, has excellent ability of anti-collapse, and has better temperature resistance and crack sealing ability. The new drilling fluid meets the needs of drilling under complicated geological conditions completely.

Introduction

Wellbore instability is one of the most important factors that constraints the speed of Exploration and Development of Huoyanshan tectonic in Tuha Basin currently. In the Huoyanshan tectonic zone, coal-bed and coal seam were well-developed, carbonaceous mudstone is thick, borehole walls collapse easily, causing stuck and other complex cases. Piedmont tectonic belt was a large dip angle and homogeneous formation, hard and soft rock formations staggered development. The drilling processes are easy well deflection and form a keyway so that the bit blocked many times. In addition, coal, sand and mudstone staggered distribution, crevices were better development in this region, and low bearing capacity is prone to leakage. These are restricting drilling speed.

It also found that salt-gypsum rocks of Shanshan group which mainly buried in the 800m ~ 2000m. Thickness of about 1000m are prone to "shrink, dissolve, swelling, collapse" [1].Therefore, it is necessary to develop high-quality drilling fluids suitable for the Huoyanshan tectonic belt according to its instability mechanism, so that we can solve the problems occurred in the process of drilling which restrict the development of drilling, improve the mechanical drilling rate, shorten the construction cycle.

Treating agent optimization

Inhibitors optimization. Cuttings were used in the experiment taken from Qigu group of WenXi block. Configuring different concentrations of inhibitors with water conducted 40 mesh aging recovery experiments (120℃, 16h), then calculating the recovery rate of rock. The experimental results are given in table 1. When the concentration of inhibitor ZNP-1 is 0.5%, the aging recovery was 78.8% higher than all the other inhibitors. It indicated that ZNP-1 can better inhibit shale hydration and dispersion, has better ability to prevent collapse.

Fluid Loss Additive Optimization. We select fluid loss additives which are commonly used in drilling design of block such as NaHPAN, HS-2, PSC, SHR, CXB-2, then evaluating the effect of the five kinds of fluid loss additives in the base slurry. The results are shown in figure 1.

Table 1. Inhibitor optimization experimental results

Inhibitor	Concentration[%]				
	0.1	0.2	0.3	0.4	0.5
YFKN	55.5	59.6	67.5	69	70.6
ZNP-1	59.5	67.1	75.8	77.2	78.8
FA-367	57.2	62.2	68.8	70.6	71.4

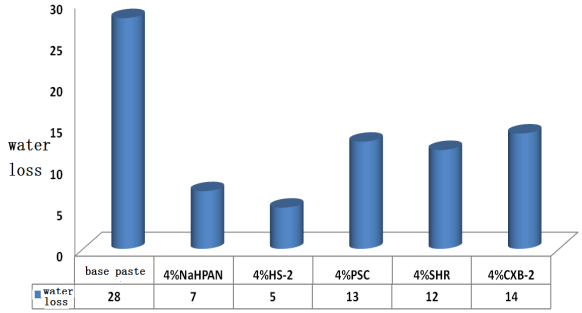

Figure 1. Fluid loss additive optimization

We can see that the filtration of NaHPAN, SHR, HS-2 solution were 7 ml, 12 ml and 5 ml respectively and less than others after added five same concentration treating agent in the base slurry. Therefore, we initially preferred the three kinds of fluid loss additive.

Lubricant Optimization. We select four kinds of lubricant which are commonly used in drilling design such as crude oil, JXFQ-2, MEG, polymeric alcohol and evaluated its lubricity by measuring the rheological properties parameters before and after hot aging of drilling fluid. The results are presented in table 2. By contrast, we can find that the emulsified crude oil has better lubricating effect, can significantly reduce the coefficient of friction of drilling fluid. Therefore, we optimized the crude oil as lubricant preliminary.

Table 2. Different lubricants impact on drilling fluid performance

Formula	Condition	AV[mPa•s]	PV[mPa•s]	YP[Pa]	Lubrication coefficient	FL[mL]
4% Crude oil	Before hot aging	7.25	4.5	2.81	0.0217	15.2
	After hot aging	8.25	5.5	2.81	0.0239	16.2
2%JXFQ-2	Before hot aging	7.25	4.5	2.81	0.2699	20.4
	After hot aging	11	7	4.09	0.1946	28
2%MEG	Before hot aging	7.5	5	2.56	0.2368	17.6
	After hot aging	10	6	4.09	0.2126	24
2% Polymeric alcohol	Before hot aging	8	4	4.09	0.0609	17.2
	After hot aging	11	5	6.13	0.0653	22

Drilling fluid formula determined. According to the Block's well-bore instability mechanism and the new principles of "Materialized blocking, inhibiting surface hydration, effective stress support" multiple collaborative anti-sloughing drilling fluid, we developed a new drilling fluid system according to the best ratio of the reagent concentration. The formula is as follows: 4% bentonite slurry + 0.15% ZNP-1 + 0.4% NaHPAN +3% SHR +3% HS-2 +4% emulsified crude oil + 3% DBFT-201 +0.5% DF-1 (marked for TH formula).

We tested the rheological properties of TH drilling fluid by contrast the experimental data (Table 3) before and after hot aging (120℃ ,16h). The rheological and filtration of TH formula were relatively stable before and after aging. The filtration of high temperature and high pressure compared low was 7.5mL. So TH is a better drilling fluid formulation.

Table 3. Rheological experimental results of TH formula

Formula	Condition	AV [mPa•s]	PV [mPa•s]	YP [Pa]	Gel [Pa·Pa-1]	Lubrication coefficient	FL [mL]	HTHP [mL]
TH	Before hot aging	44	38	6.13	1.53/14.31	/	1.8	/
	After hot aging	41.5	36	5.62	0.77/2.56	0.1282	1	7.5

TH formula evaluation

Anti-pollution Evaluation. Drill cuttings are the main solid phase pollutants in drilling fluid and always present in the drilling process. Therefore, it is required that the drilling fluid should have a certain capacity of anti-contaminated to prevent the performance of the drilling fluid from occurring fluctuations [2].

Table 4. Anti-pollution experimental results of TH formula

Formula	Condition	AV [mPa.s]	PV [mPa.s]	YP [Pa]	Gel [Pa*Pa-1]	FL [mL]	HTHP [mL]	Lubrication coefficient
TH	Before hot aging	51	39	12.26	2.04/12.78	1.2	/	0.1315
	After hot aging	59	47	12.26	1.53/9.71	1.7	7.5	
TH+10 %NaCl	Before hot aging	65.5	22	44.46	25.04/41.9	1.4	/	0.1329
	After hot aging	31	30	1.02	0.51/9.2	1.7	18	
TH+8% poor soil	Before hot aging	51	40	11.24	2.56/14.31	3.2	/	0.1375
	After hot aging	68.5	56	12.78	2.04/10.73	3.6	7.2	
TH+0.5 %CaCl2	Before hot aging	44	38	6.13	1.53/14.31	1.8	/	0.1282
	After hot aging	41.5	36	5.62	0.77/2.56	1	13	

Adding 10% NaCl, 8% poor soil and 0.5% CaCl2 in TH formulation respectively, contrast the experimental data (Table 4) of hot aging experiment (120℃, 16h) found that the viscosity, shear force and filtration of contaminated drilling fluid before and after aging did not occur mutations, indicating that it has a strong anti-salt, anti-calcium, anti-poor soil capacity.

Anti-collapse Evaluation. In strict accordance with the steps of inhibitor optimization experiments conducted 40 meshes aging recovery experiments (120℃, 16h) to compare the shale recovery in water, polysulfonate pulp of Yubei2 well and TH formula. Experimental results show that the shale recovery of TH formula was 82.47%, polysulfonate pulp of Yubei2 well was 68.73%, and water was 37.27%. Obviously, the new formula TH drilling fluid can effectively inhibit shale hydration, prevent debris scattered damage of drilling fluid rheology and filtration wall building, it has excellent anti-collapse performance.

Inhibition of clay hydration expansion ability evaluation. According to the method of literature [3] conducted the experiment of inhibiting expansion, and calculated linear expansion percentage of the rock sample in different drilling fluid. We find TH formula expansion rate was the minimum. Inflation rate in 8 h was only 2.08%, with excellent capability of inhibiting clay hydration expansion.

Anti-temperature capability Evaluation. Oil layer of Huoyanshan tectonic zone buried deep. The well bottom's temperature reached above 130℃. It was required the drilling fluid still has excellent rheological properties after high temperature aging. Therefore, it was necessary to evaluate the anti-temperature performance on TH drilling fluid [4]. We put the TH drilling fluid system in 120 ℃, 130 ℃ and 150 ℃ containers respectively with high temperature hot aging 16h to evaluate the stability of TH formula. The results are shown in table 5. By contrast, we found that the rheological and

filtration properties of the system before and after aging have not mutated, the viscosity decreased little by aging. TH formula has a better ability to resist temperature, to be able to meet the needs of the deep well drilling for Huoyanshan block.

Sealing performance evaluation. We Put TH drilling fluid system in the same leakage bed (400μm crack) and different pressure to determine its loss after 3 min. We found TH formula's bearing capacity reached 4 Mpa (leakage was only 1.6mL), has good ability for crack sealing.

Table 5 Anti-temperature capability experimental results

Formula	Condition	AV [mPa.s]	PV [mPa.s]	YP [Pa]	Gel [Pa*Pa-1]	FL [mL]	Lubrication coefficient
TH	Before hot aging	60	45	15.33	2.56/15.33	2.8	0.1321
	120℃hot aging	49	38	11.24	1.02/8.18	2.8	
	130℃hot aging	38.5	31	7.67	0.51/15.33	2.2	
	150℃hot aging	33.5	28	5.62	1.02/5.62	2.6	

Field Application

YuBei block of tuha oilfield occurred sticking twice, blocked one time, lost three times, gas cut one time in the process of drilling according to the drilling statistics. The block is a typical Huoyanshan tectonic, and the reasons of complex accidents are conforming to the foreword's analysis.

In 2013, we applied the TH drilling fluid system to 8 Wells in this block, including four preliminary exploratory well (depth were more than 4000 m), two production Wells (depth were 4070 m and 3982 m), a development well (depth was 3878.98 m) and a injection Wells (depth was 4194 m). The total processing time for lost circulation and sticking was 65.33 h, for the well logging instrument sticking was 151.5 h. There was not blocked, gas cut and other complicated conditions. The average drilling cycle was 47.57 days, and shortened by 26.38% than the early stage. The loss rate of complex accidents was reduced from 27.3% to 2.12%. These all indicate that the newly developed TH drilling fluid system can meet the demands of exploration and development of Huoyanshan structure.

Conclusions

(1) The main complex accidents in Huoyanshan structure were sticking, blocked and leakage. According to the block's wellbore instability mechanism and the new principles of "Materialized blocking, inhibiting surface hydration, effective stress support" multiple collaborative anti-sloughing drilling fluid, we optimized the new type of TH drilling fluid formulation by laboratory experiments.

(2) The results of experiments and the application show that TH formula has a strong anti-salt, anti-calcium, anti-poor soil capacity, excellent anti-collapse, inhibiting clay hydration expansion, resist temperature and fracture plugging performance. It can greatly reduce the failure rate, increase the rate of penetration, shorten the construction cycle, shorten the time of drilling fluid immersion hydrocarbon reservoir, and decrease the damage to the hydrocarbon reservoir. TH drilling fluid completely meets the needs of drilling under the complex geological conditions.

Vertical zonation in penecontemporaneous period of the bauxite in WZD area

Tao Cui

College of Resources and Environmental Engineering, Guizhou Institute of Technology, Guiyang, 550003, China

cuitao1203@163.com

Key words: WZD area; Bauxite; Vertical zonation

Abstract: Through systematically geologic survey and observation of drills, this paper have a comprehensive research on Vertical zonation in bauxite deposit of Wuchuan-Zheng'an-Daozhen (WZD) area. Environment of WZD bauxite in penecontemporaneous period can be divided into two parts: vadose zone and phreatic zone. Vadose zone is oxidized and acidic environment. Phreatic zone is reduced and alkalescent environment. Vadose zone is favorable to mineralization, but phreatic zone is not favorable to mineralization.

Introduction

There is abundant bauxite in WZD area. For a long time many experts and scholars have researched on rocks and minerals, chemistry, sedimentary environment, provenance, mineralization age, and mass balance calculation of the bauxite [1-15]. Though there are abundant outcomes of WZD bauxite, analysis on vertical zonation of the bauxite is poor. This study is to establish vertical zonation model of WZD bauxite through the research on Vertical alternation, which accelerates the research on mineralizaton process of high grade bauxite.

Geological setting

WZD bauxite is located in Wuchuan, Zheng'an and Daozhen County, northern Guizhou, which is an important part of centre Guizhou-southern Chongqing bauxite belt [7]. The regional tectonics position of the study area is in the fold belt in northern Guizhou of the upper Yangtze Block [8]. From the oldest to the youngest, the main strata in WZD area includes Cambrian, Ordovician, Silurian, Permian, Triassic and Jurassic. Cambrian is mainly distributed in the core of anticlines, Triassic and Jurassic are mainly distributed in the core of synclines. Bauxite underlies the LiangShan formation(P2l) or Qixia formation(P2q) in the middle Permian, and overlies the HuangLong formation(C2h) of upper Carboniferous or the Hanjiadian formation of the lower Silurian(S1hj). The bauxite is stratiform and unconformable with the underlying and overlying strata. Fig.1 shows that the distribution of the bauxite is controlled by nine synclines. Thickness of the bauxite is 0.68-15.7m, and its profile can be divided into two lithology parts: the upper part and the lower part. The former is aluminous rock, dominated by high grade bauxite or half grade bauxite; the latter is low grade bauxite. According to the lithological and textural properties, the natural types of bauxite deposit can roughly be subdivided into four categories: massive bauxite, oolithic bauxite, clastic bauxite and earthy bauxite.

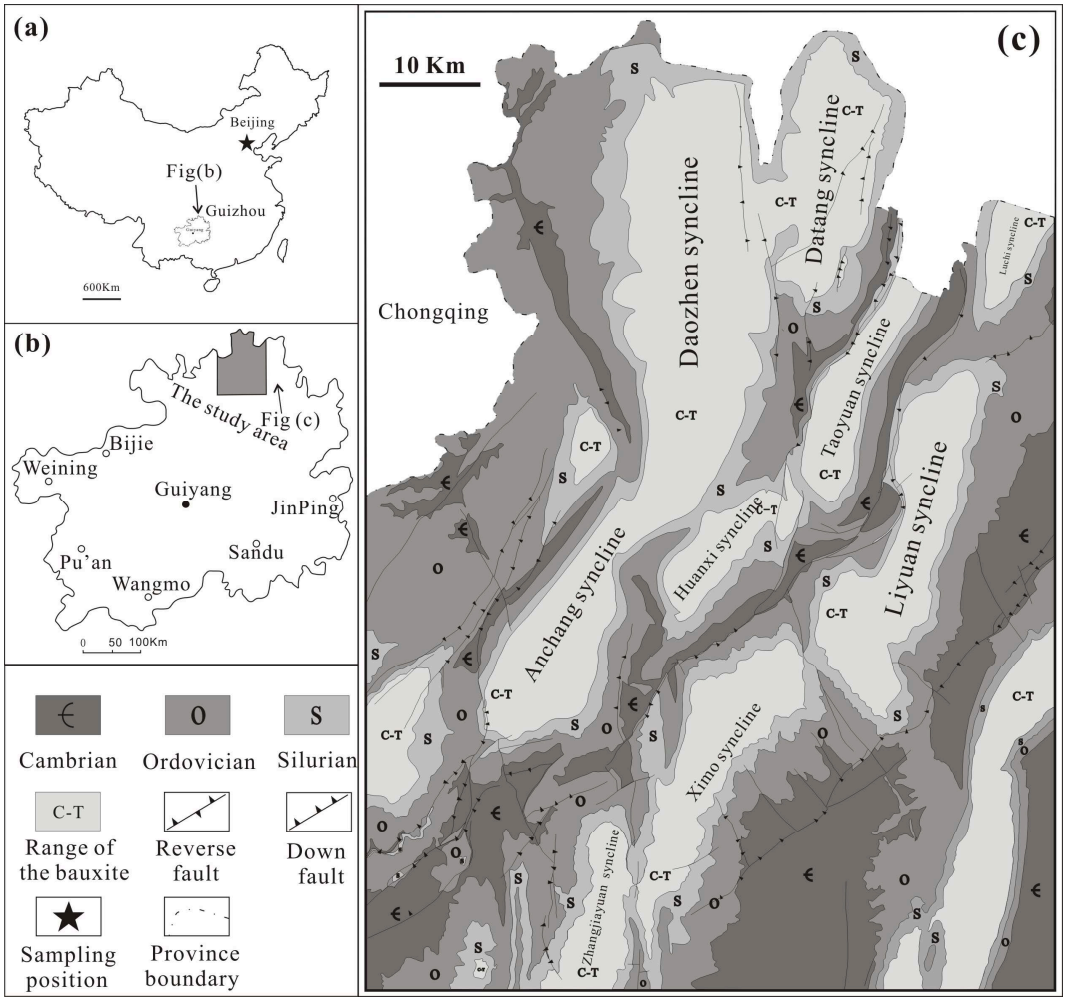

Fig. 1(a)Locality map of Guizhou,(b)The map showing the location of the study area, (c)Geology map of the WZD area in northern Guizhou

Vertical zonation

Vertical diversity of metallogenetic environment resulting in vertical regular alteration such as color, structure and composition of the WZD bauxite. Leaching process causes vertical differentiation of chemical nature in profile. Actually Leaching process is a transport process of groundwater, so we can divide vertical environment of the WED bauxite based on the zonation of groundwater. Environment can be divided into vadose zone and phreatic zone. Vadose zone is the area that pore space water take reaction with deposition, under groundwater is phreatic zone. We can distinguish Vadose zone and phreatic zone roughly based on color (Fig.2). Fig.2 shows that bauxite is light grey to red in Vadose zone, but bauxite is dark grey to green in phreatic zone. Position of Vadose zone and phreatic zone are variable as the shifted of phreatic surface. Between vadose zone and phreatic zone chemical nature have assembled characteristics of vadose zone and phreatic zone, so bauxite from different drills in this transition zone would present different feature. Bauxite in vadose zone is high grade and contains abundant diaspore and ooliths. Ores in vadose zone is loose and porous, and there are some red substrate in bauxite. Bauxite in phreatic zone have a deep color relative to the bauxite in vadose zone, and it just contain small oxydic substrate. Bauxite in phreatic zone is usually low grade with a high content of Fe and a low content of Al. Surface of bauxite in phreatic zone is usually smooth, and contain spherical grain or epidermal oolitics. Pyrite is common in vadose zone and phreatic zone.

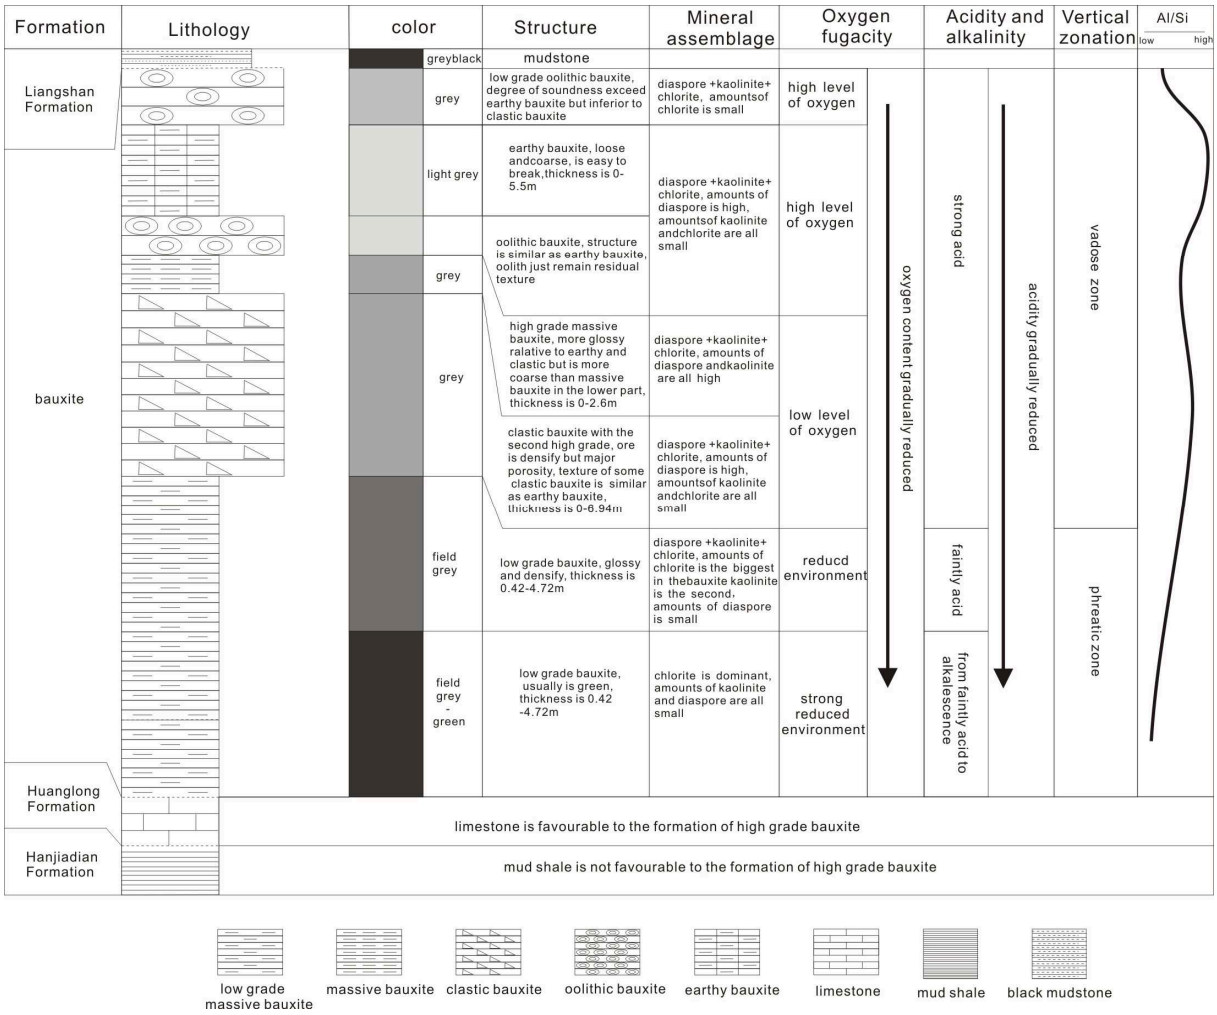

Fig.2 Vertical zonation of environment in penecontemporaneous period on WZD bauxite

Conclusions

The main conclusions from this study are summarized as follows: 1) in penecontemporaneous period environment can be divided into two parts: vadose zone and phreatic zone. Vadose zone is oxidation and acidic environment; phreatic zone is reduced and alkalescent environment. 2）Vadose zone is favorable to mineralization, but Phreatic zone is not favorable to mineralization. 3) The lower the phreatic surface is, the more conducive to mineralization.

Preservative features of the fossils in bauxite deposit of WZD area, Northern Guizhou, China

Tao Cui

College of Resources and Environmental Engineering, Guizhou Institute of Technology, Guiyang, 550003, China

cuitao1203@163.com

Keywords: WZD area; Bauxite; fossils

Abstract: It is hardly to discovery fossil from the bauxite in Wuchuan -Zheng' an-Daozhen (WZD) area, northern Guizhou, China. But the new study suggests, containing a small amount of plant debris from massive bauxite in the lower part of the ledge. Preservative features of fossils in WZD bauxite indicates: metallogenetic materials experienced a transport process; sedimentary environment is reduced; fossils only preserved in the massive bauxite, that fossils in other types of ores were destroyed in the late oxidation modification. Metallogenic environment of bauxite has experienced two kinds of state- reduction and oxidation. The lack of animal fossils; bauxite, reveal that the metallogenic environment is acidic, resulting in animal fossils are dissolved and hard to save.

Introduction

There is abundant bauxite in the WZD area. For a long time many experts and scholars have research on the bauxite of rocks and minerals, chemistry, sedimentary environment, provenance, mineralization age [1-6]. As bauxite in other areas WZD bauxite just has small fossils, but these small fossils would supply important metallogenetic information for research. There are small amount of phytolite in the WZD bauxite, this paper has an analysis on the preservative features of these fossils to research metallogenetic environment and metallogenetic process of the WZD bauxite.

Geological setting

WZD bauxite is located in Wuchuan, Zheng'an and Daozhen County, northern Guizhou, which is an important part of centre Guizhou-southern Chongqing bauxite belt [7]. The regional tectonics position of the study area is in the fold belt in northern Guizhou of the upper Yangtze Block[8]. The main strata in WZD area from the oldest to the youngest including: Cambrian, Ordovician, Silurian, Permian, Triassic and Jurassic. Cambrian is mainly distributed in the core of anticlines, Triassic and Jurassic are mainly distributed in the core of synclines. Bauxite is underlying the LiangShan formation(P2l) or Qixia formation(P2q) of the middle Permian, overlying the HuangLong formation(C2h) of upper Carboniferous or the Hanjiadian formation of the lower Silurian(S1hj).The bauxite is stratiform and unconformable with the underlying and overlying strata. Fig.1 shows that the distribution of the bauxite was controlled by nine synclines. The thickness of the bauxite is 0.68-15.7m, the profile can be divided into two lithology parts: the upper part is aluminous rock, dominated by high grade bauxite or half grade bauxite; the lower part is low grade bauxite. According to the lithological and textural properties, the natural types of bauxite deposit can roughly be subdivided into four categories: massive bauxite, oolithic bauxite, clastic bauxite and earthy bauxite.

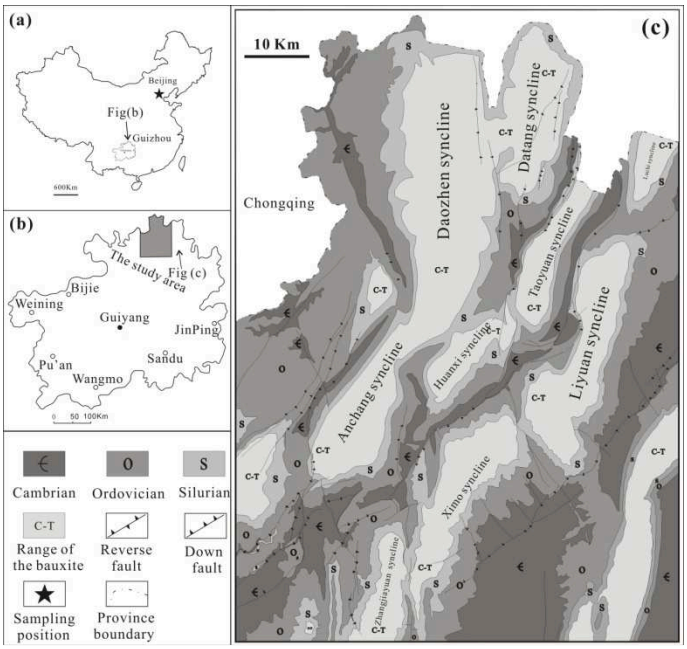

Fig. 1(a)Locality map of Guizhou,(b)The map showing the location of the study area, (c)Geology map of the WZD area in northern Guizhou

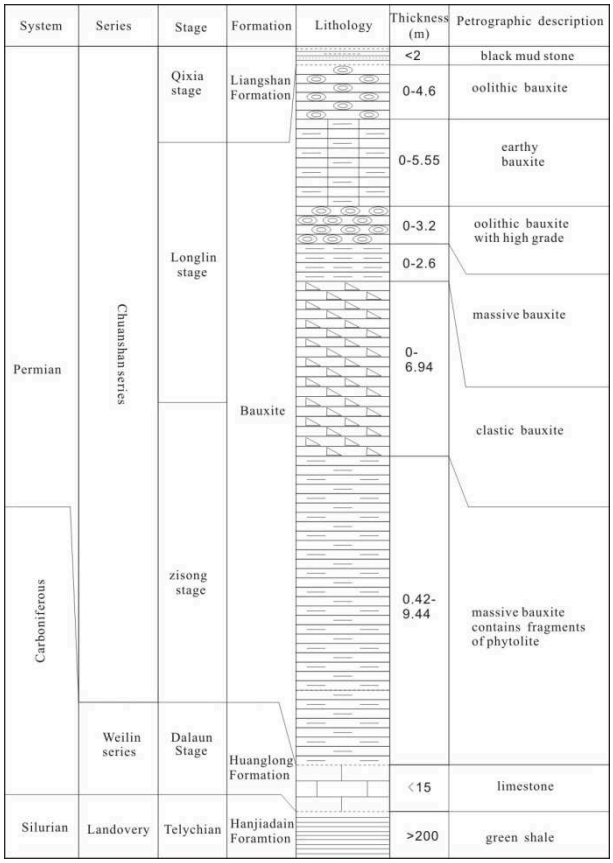

Fig.2 Column shows the location of fossils [8]

Preservative features of the fossils

Fig.2 shows that plant fragment of fossils just preserved in the massive bauxite in the lower part of the producing formation, there are no fossils preserved in other types of bauxite. Plant fossils are elongate or scaly, length of fossils can over 3cm (Fig.3,e,f). Plant fossils are commonly fragmented indicates that the formation of these fossils experienced a transported deposit process.

Though WZD bauxite just has small fossils, these small fossils would supply important metallogenetic information for research. Forming process of fossils need reduced environment, WZD bauxite is grey and contain some plant fragment fossils shows that sedimentary environment is reduced. There are no plant fragment fossils preserved in four types bauxite except massive bauxite, obviously fossils cannot selectively preserve. In the period of original deposition four kinds of bauxite in the WZD area contain plant fragment but plant fragment was destroyed by later metallization. Comparison of the massive bauxite and other three types of bauxite, there are obvious difference in these bauxite (Fig.3). Fig.3 shows that Massive bauxite is grey – green which is the strongest reduced color in four type bauxite. Massive bauxite is more dense and smooth than other kinds of bauxite. In the forming process of oolithic, earthy and clastic bauxite have experience a severe transform that resulting in fossils be destroyed. Metallogenic environment is not constant but altered in reduction and oxidation. There are no zoolite in the bauxite, it demonstrates that Metallogenic environment is acidic so animal remains with calcareous skeleton cannot be preserved but coaly plant remains can be preserved.

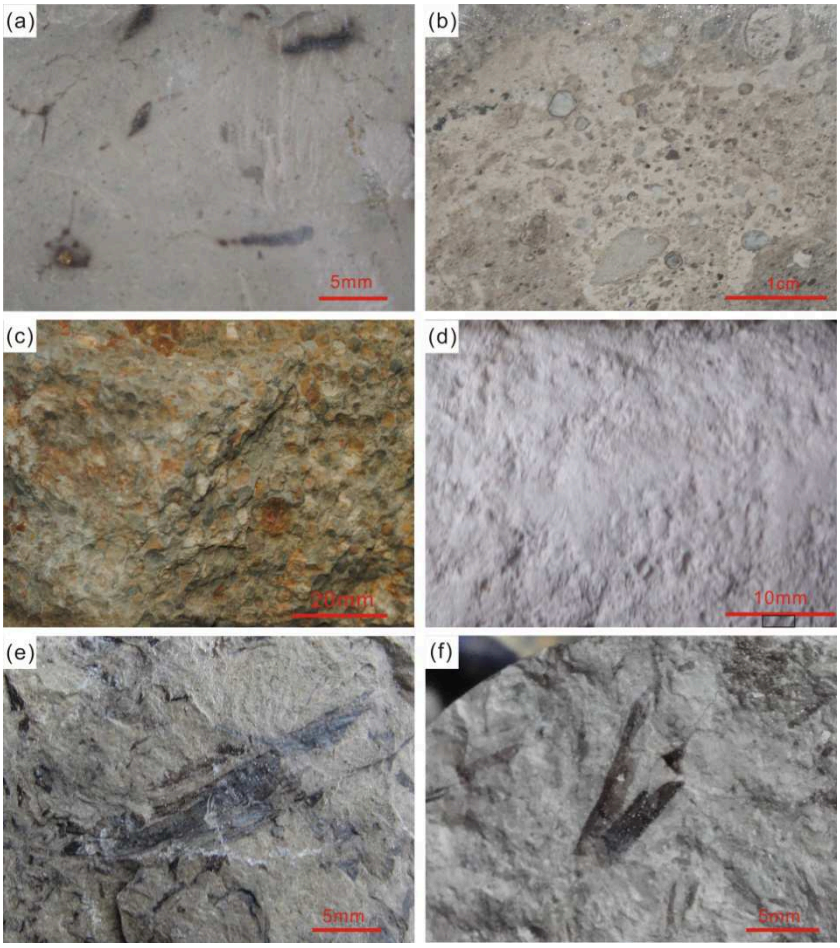

Fig.3 Fossils in the WZD bauxite: a. massive bauxite without fossil; b. clastic bauxite without fossil; c. oolithic bauxite without fossil; d. earthy bauxite without fossil; e and f. massive bauxite contain fossils

Conclusion

The main conclusions from this study are summarized as follows:1)There are some small fragments of plant fossils in the lower part of producing formation; 2) In the period of Metallogenic process metallogenic environment is not constant but altered in reduction and oxidation; 3) Metallogenic environment is acidic cause only plant remains can be preserved as fossils.

Keywords: WZD area; Bauxite; interlayer.

Abstract: Through systematically geologic survey and observation of hand specimen this paper have a comprehensive research on the characteristics of interlayers in bauxite deposit of Wuchuan-Zheng'an-Daozhen (WZD) area. There are two kinds of interlayers in WZD bauxite: black coaly interlayer and brown hematitic interlayer. Black coaly interlayer indicate reduce and inshore environment, brown hematitic interlayer represent oxidized and strong hydrodynamic environment. The appearance of interlayer with contrary feature indicate sedimentary environment of the WZD bauxite is very complex.

Introduction

There is abundant bauxite in WZD area. For a long time many experts and scholars have research on the bauxite of rocks and minerals, chemistry, sedimentary environment, provenance, mineralization age, mass balance calculation [1-15].Though there are abundant outcome of WZD bauxite, analysis on microfacies of the bauxite is poor, this study through the research on interlayers to inquiry microfacies of WZD bauxite, this work would accelerate the research on regularity of ore formation.

Geological setting

WZD bauxite is located in Wuchuan, Zheng'an and Daozhen County, northern Guizhou, which is an important part of centre Guizhou-southern Chongqing bauxite belt [7]. The regional tectonics position of the study area is in the fold belt in northern Guizhou of the upper Yangtze Block [8]. The main strata in WZD area from the oldest to the youngest including: Cambrian, Ordovician, Silurian, Permian, Triassic and Jurassic. Cambrian is mainly distributed in the core of anticlines, Triassic and Jurassic are mainly distributed in the core of synclines. Bauxite is underlying the LiangShan formation(P2l) or Qixia formation(P2q) of the middle Permian, overlying the HuangLong formation(C2h) of upper Carboniferous or the Hanjiadian formation of the lower Silurian(S1hj).The bauxite is stratiform and unconformable with the underlying and overlying strata. Fig.1 shows that the distribution of the bauxite was controlled by nine synclines. The thickness of the bauxite is 0.68-15.7m, the profile can be divided into two lithology parts: the upper part is aluminous rock, dominated by high grade bauxite or half grade bauxite; the lower part is low grade bauxite. According to the lithological and textural properties, the natural types of bauxite deposit can roughly be subdivided into four categories: massive bauxite, oolithic bauxite, clastic bauxite and earthy bauxite.

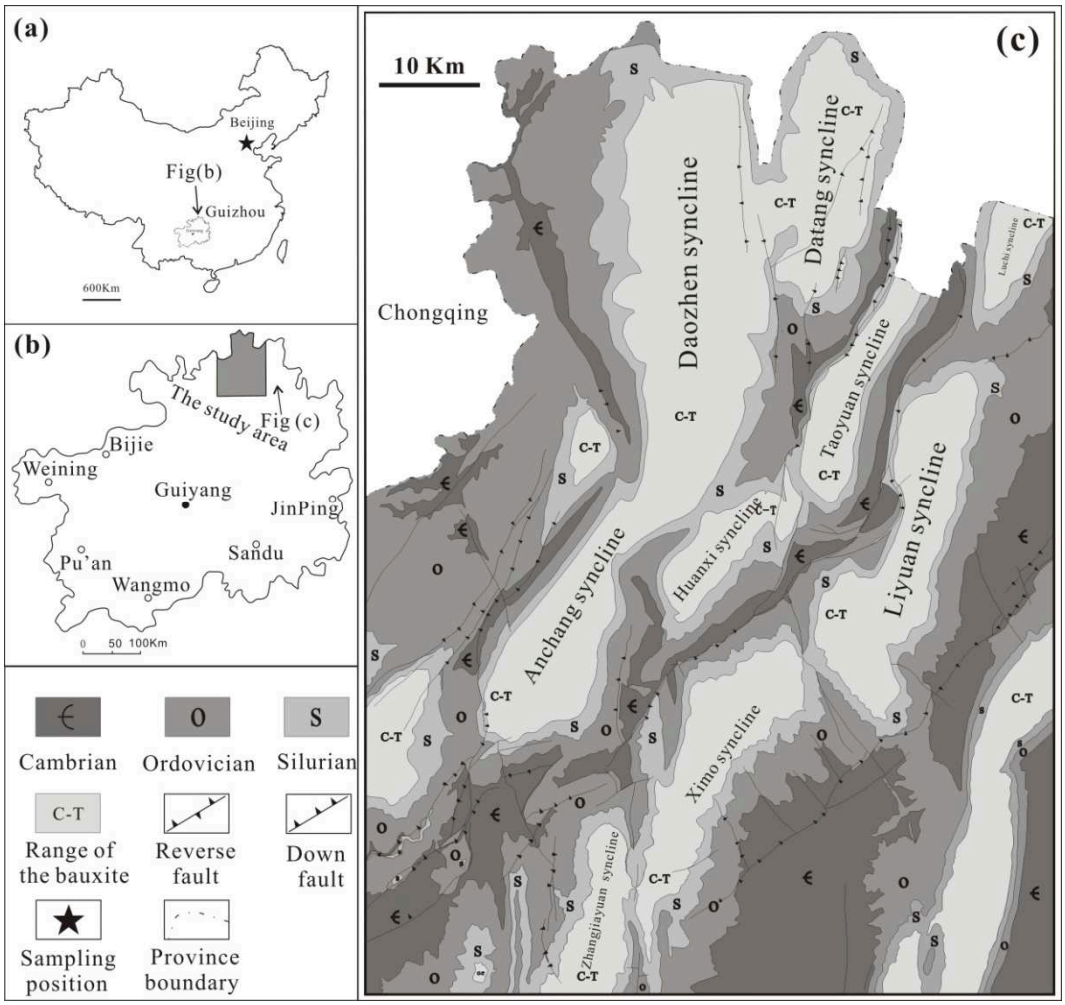

Fig. 1(a)Locality map of Guizhou,(b)The map showing the location of the study area, (c)Geology map of the WZD area in northern Guizhou

Characteristics of interlayers

Producing formation can be divided two parts: the lower part is massive bauxite, the upper part is earthy, oolothic, clastic and massive bauxite. Fig.2 shows that producing formation is grey, some drills contains black coaly interlayers and pricking dirt. Pricking dirt is thin but black coaly interlayers are thick, the thickness of the pricking dirt is 15cm (Fig.2,a,b), the thickness of the black coaly interlayers is from0.15to2m, black coaly interlayers are jetty (Fig.2,c,d,e,f). Brown hematitic interlayer has been discovered in Zhangjiayua syncline(Fig.2,g,h), southern of the study area(Fig.1).The thickness of the hematitic interlayer is 3.5m. Black coaly interlayers is frequent in WZD area and it usually appears in the upper of the producing formation. Brown hematitic interlayer is rare in the study area. Black coaly interlayers and brown hematitic interlayer indicate adverse sedimentary environment, they appear at the study area show that sedimentary environment of WZD bauxite is very complex. Sedimentary environment of WZD bauxite is reduced but part of the study area is oxidized. Sedimentary environment has changed into swamp resulting in black coaly interlayers frequent appear in the study area. Brown hematitic interlayer instants inshore and high energy environment, it shows that bauxite deposit would formed in transition facies.

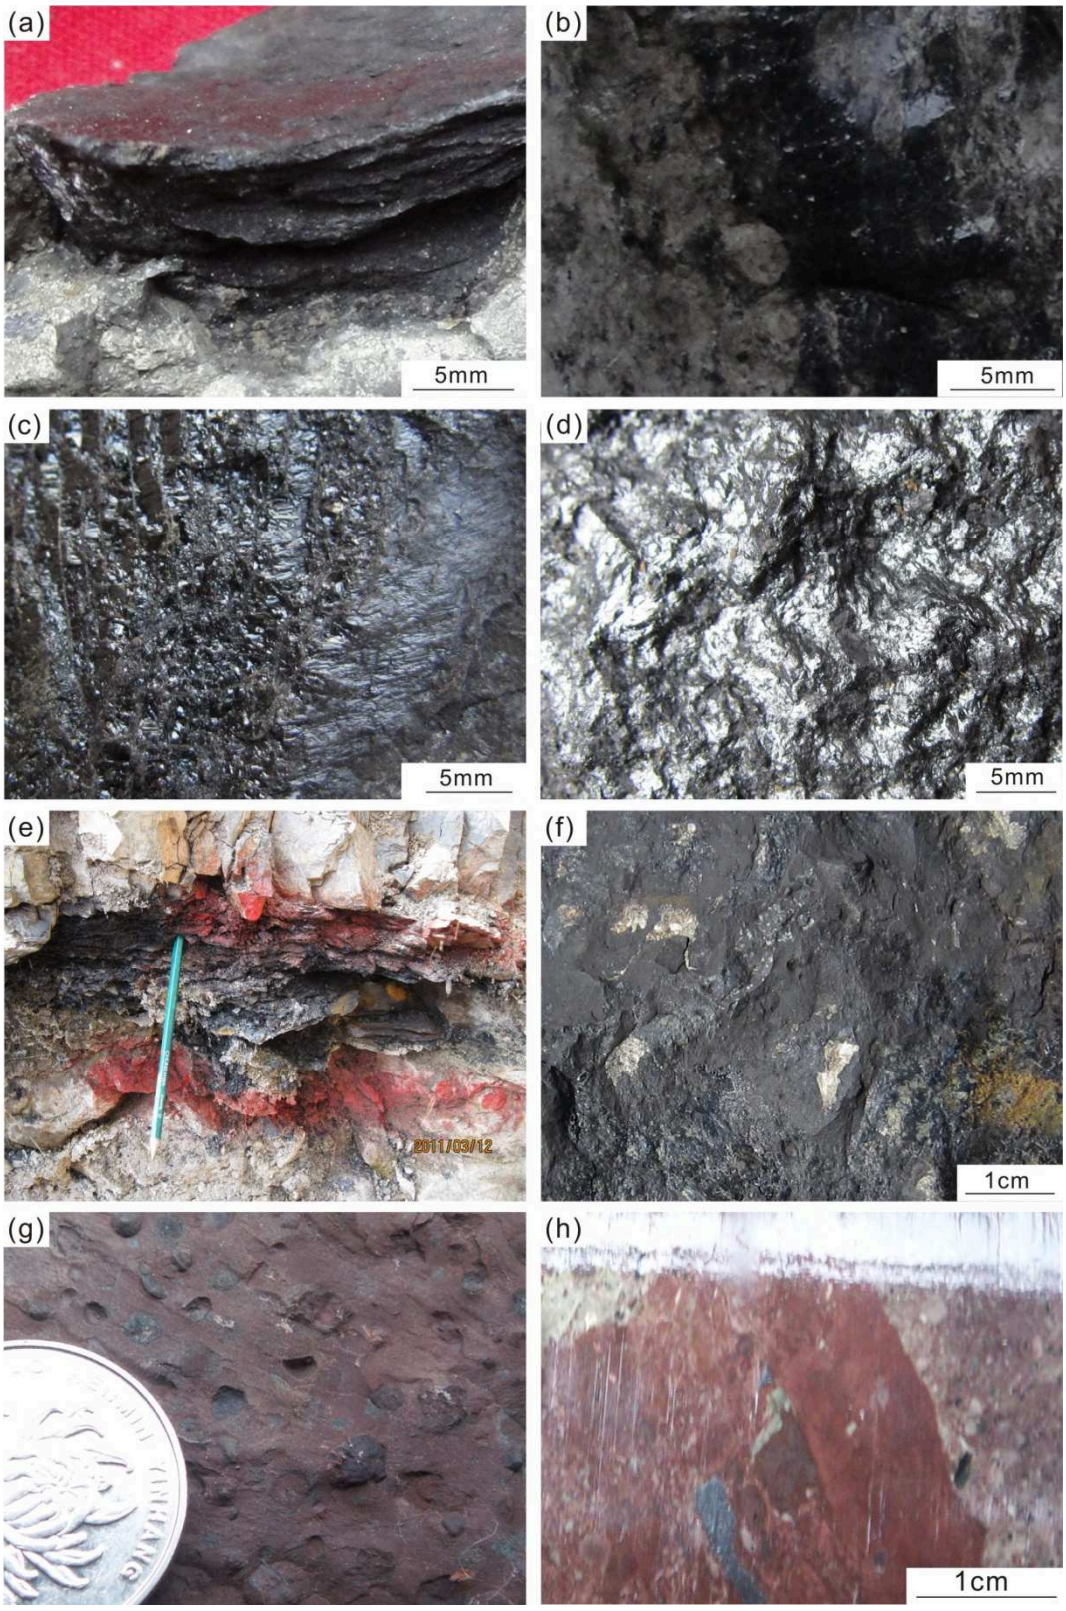

Fig.2 Black coaly interlayer and brown hematitic interlayer in WZD bauxite;a, pricking dirt;b. pricking dirt; c. black coaly interlayer; d.black coaly interlayer;e. black coaly interlayer;f. black coaly interlayer; g.brown hematitic interlayer; h.brown hematitic interlayer

Conclusion

The main conclusions from this study are summarized as follows: 1) Black coaly interlayer indicates sedimentary environment of WZD bauxite is reduced, WZD bauxite was formed in a inshore environment. 2) Black coaly interlayer is thin and discontinuous shows that sedimentary

environment has transformed into swamp but did not occur large and long time expose. 3)Oolithic hematite and brown interlayer shows that part of sedimentary environment is oxidize and energetic.

Research progress of bauxite in WZD area, northern Guizhou, China

Tao Cui

College of Resources and Environmental Engineering, Guizhou Institute of Technology, Guiyang, 550003, China

cuitao1203@163.com

Keywords: WZD area; Bauxite; Progress

Abstract: This paper has a comprehensive analysis on the bauxite in Wuchuan -Zheng, an-Daozhen (WZD) area, northern Guizhou, China through synthesize former research. The understanding of mineralogic, petrologic and geochemical characteristics is deep, and sedimentary environment, parent rock and mineralization process have been defined. Main questions need further research as follow: minerogenetic epoch; migration mechanism of elements; genesis of rare earth mineral.

Introduction

There is abundant bauxite in WZD area. For a long time many experts and scholars have research on te bauxite of rocks and minerals, chemistry, sedimentary environment, provenance, mineralization age [1-11]. This work synthesize data of former researcher to have a comprehensive understanding on the progress of WZD bauxite.

Geological setting

WZD bauxite is located in Wuchuan, Zheng'an and Daozhen County, northern Guizhou, which is an important part of centre Guizhou-southern Chongqing bauxite belt [7]. The regional tectonics position of the study area is in the fold belt in northern Guizhou of the upper Yangtze Block[8]. The main strata in WZD area from the oldest to the youngest including: Cambrian, Ordovician, Silurian, Permian, Triassic and Jurassic. Cambrian is mainly distributed in the core of anticlines, Triassic and Jurassic are mainly distributed in the core of synclines. Bauxite is underlying the LiangShan formation(P2l) or Qixia formation(P2q) of the middle Permian, overlying the HuangLong formation(C2h) of upper Carboniferous or the Hanjiadian formation of the lower Silurian(S1hj).The bauxite is stratiform and unconformable with the underlying and overlying strata. Fig.1 shows that the distribution of the bauxite was controlled by nine synclines. The thickness of the bauxite is 0.68-15.7m, the profile can be divided into two lithology parts: the upper part is aluminous rock, dominated by high grade bauxite or half grade bauxite; the lower part is low grade bauxite. According to the lithological and textural properties, the natural types of bauxite deposit can roughly be subdivided into four categories: massive bauxite, oolithic bauxite, clastic bauxite and earthy bauxite.

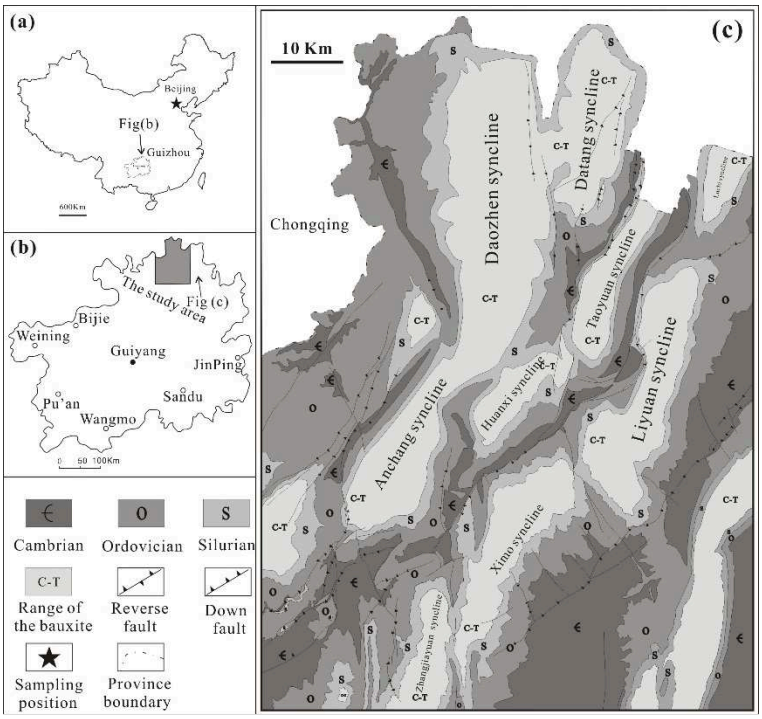

Fig. 1(a)Locality map of Guizhou,(b)The map showing the location of the study area, (c)Geology map of the WZD area in northern Guizhou

Mineralogy and petrology

The Length of mineralogical crystal of WZD bauxite is no more than 5μm. Bauxite is mainly composed of diaspora and clay minerals like kaolinite, chlorite and illite, and contains a bit of heavy minerals, such as anatase, zircon and rutile, and minute quantity of quartz, feldspar and pyrite[1,2,5,6,7,8,9]. Striped and elliptic spherical parasites (Ce2Ca(CO3)3F2) have been recognized in ZK14904, ZK3402 and ZK9A04. Binary structure of bauxite is clear, generally, diaspore takes the content of 40%-95% in the middle- upper part, the rest are mainly clay minerals like kaolinite, chlorite and illite etc. Bauxites achieving the industrial grade mainly distributes in this part. The lower part is dominated by clay minerals, diaspore takes the content of 5%-40%, while clay minerals can reach up to 95%. Constant compositions of bauxite are Al2O3 (26.13-75.16%), SiO2(4.52- 44.46%), Fe2O3(0.77- 27.67%)and TiO2(1.05- 5.24%), these elements have wide distributions[9].

Geochemistry

Al_2O_3 has negative correlations with SiO_2 and Fe_2O_3, while displays positive correlation with TiO_2, indicating bauxite metallogenic process is a process enriching Al, Ti and losing Si, Fe[9]. Trace elements of Zr, Cr, V and Li are enrichment in bauxite. In parallel, Zr, Hf, Nb, Ta and Cr with similar changing rules display an increasing trend in content from north to south, while in vertical, the content shows an opposite trend from the top to the bottom of the section. Contents of Zr, Cr and Nb are relatively high, Zr is up to 1835ppm, Cr, V, Li are more than 150m. Hf and Ta are relatively low. Ni is special with different changing rules from other elements both in parallel and vertical [9]. The contents of Ni in the samples are significantly different. Ranges of LREE, HREE, ΣREE in bauxite are 18.49×10^{-6}- 993.6×10^{-6}, 12.7×10^{-6}- 47.3×10^{-6}, 38×10^{-6}- 1040.9×10^{-6}, respectively, average values are 198.82×10^{-6}, 26.3×10^{-6}, 225.1×10^{-6}[6,9]. LREE, HREE, ΣREE show an increasing trends from top to the bottom of the drill section. LREE displays large variation, while HREE has the opposite trend positive anomaly of Ce in the drill is obvious[6].

Provenance

Source tracing of trace elements is simple and reliable. Cr-Ni, Zr, Hf, Nb, Ta have been used to analyse the sources of bauxite. Cr- Ni value has a wide distribution in WZD bauxite, indicating parent rocks of aluminosilicate rocks and carbonatites and small part of basalt parent rocks [9]. High Field- Strength Elements (HFSE) Zr- Hf and Nb- Ta chart indicate mud shale of Hanjiadian formation has a closer relationship with bauxite [6, 9]. Source tracing of trace elements indicates mud shale of Hanjiadian Formation and limestone of Huanglong Formation are important material sources of bauxite, and mud shale of Hanjiadian Formation even contribute more to bauxite. Besides, there is another small part of basalt provides metallogenic material to bauxite.

Sedimentology

The iron weathering crust, less than 1m has been discovered at the bottom of ore-bearing rock series of bauxites. The ore-bearing rock series is composed of clay rocks and bauxites [10,11]. Clay rocks exhibit homophaneous structure. Bedding and fossils are absent in the ore-bearing rock series of bauxites. Black carbonaceous interbeds and inferior coal interlayer appear in some drills. All these characters of bauxite indicate the forming environment should be low energy lacustrine, bay or coastal lagoon[10,11].

It is suggested that WZD bauxite formed in a special dynamic environment, from evidences of the mineral assemblages, outcrop charaters, geochemistry of trace elements and REE of bauxite, subjective environment is partly closed bay. Although the sea level is fluctuated, the sedimentary environment switched between partly closed bay and terrestrial lake. When the sea level was high, metallogenic province connected with Yangtze Sea, it appears to be salt- brackish water sedimentation. When the sea level was low, metallogenic province out of touch with sea, it appears to be terrestrial salt- brackish water sedimentation. The input of atmospheric precipitation and land fresh water, salt water was diluted constantly. After a period of desalination, some areas changed into fresh water environment. The degree and scale of desalination are determined by length of time of desalination. After lacustrine salt or brackish water totally desalted, sedimentary environment became a brackish water or salt water environment again over the next transgression. After the sea level reduced, lacus or partly closed bay experienced desalination again [11]. In this cycle, metallogenic environment switched in terrestrial lacus, partly closed bay and bay, paleosalinity was in the transition between fresh- brackish water- salt water, so that the sedimentation of bauxite have both continental and transitional characters.

Conclusion

The main conclusions from this study are summarized as follows:1)Former research have a depth understanding on the mineralogy, petrology and geochemistry of WZD bauxite;2)The problems of provenance,sedimentary environment and mineralization process have been resolved;3) We need a further research on three questions as follow: minerogenetic epoch, migration mechanism of elemthreents; genesis of rare earth mineral.

Keywords: Borehole camera, coral reef, integrity evaluation, RMDI.

Abstract. At present, relatively few drilling surveys have been conducted on coral reefs, and comprehensive geological info on coral reefs is difficult to obtain. However, research of coral reef is of great importance to our development and exploitation of maritime resources. The survey of South China Sea some Islands saw China's first usage of digital borehole camera technology, which resulted in a large amount of first-hand geological data. Because the coral reef, special rock mass, integrity evaluation is very difficult, we proposed the RMDI and coring rate comparative analysis method. The evaluation method is applied to the South China Sea some Islands, and the evaluation results prove generally consistent with actual cores. The results indicate that: (1) high-resolution borehole images can provide reliable results for evaluation of coral reef integrity; (2) The RMDI and coring rate comparative analysis method is a feasible approach for the evaluation of coral reef integrity along the full or partial depth of a borehole.

Introduction

Coral reefs are rock and soil structures formed by the remains of scleractinian corals after long-term geological effects[1]. The research of coral reef is of great importance to our development and exploitation of maritime resources. The main component of coral reef is calcium carbonate ($CaCO_3$). It is porous and brittle, low in both hardness and strength. Drilling is an indispensable method in the background survey of coral reefs, but due to characteristics of their structure and limitations of technology, such as mechanical disturbances which may result in low or even zero coring rate, the geological info obtained is often incomplete, rendering traditional analytical methods inaccurate. As coral reefs tend to shatter under high pressure, it is easy for the drilling process to damage the intactness of coral rocks, which is impossible to determine through rock cores. Therefore, a singular reliance on drilling would affect the accuracy of coral reef research and even cause erroneous results. A better evaluation of their rock mass would require a combination of drilling and other complementary techniques. The digital borehole camera system [2,3,4] has integrated digital video and computer control by using optical sensors for close observation of rock mass inside the borehole. The acquired information is processed with computer to generate digital column-shaped image of the borehole walls, solving the integrity and accuracy problem of geological info acquisition in coral reef boreholes.

Rock mass integrity refers to the extent of development of various geological interfaces, mainly the fissures and faults. It is a generalized representation of the rock mass structures, and is determined by many factors including the shearing of structural planes, the sizes of structural bodies, and the cementation between bodies. A high-integrity rock mass has fewer faults, and a low-integrity rock mass contains more faults. It is one of the most important signifiers of rock mass quality, used in rock engineering as an overall indicator. Thus it is significant for rock engineering to find methods that allow simple and scientific evaluation of rock mass integrity.

Borehole Camera

The key to the digital panoramic borehole camera system lies in breakthroughs of panoramic (reflector on the conical surface) and digital (digital video and imaging) technologies. The panoramic technologies enable a 2-dimensional representation of the 360° borehole wall, which is overlayed with directional info, creating a panoramic image; digital technologies allow the digitization of videos, which are processed with inverse transformation algorithms to construct a model of the borehole wall and generate a digital vertical image. The borehole camera image is an intuitive representation of geological info from the borehole wall. By processing this info, a complete database can be generated. Fig.1 is a schematic diagram of borehole camera imaging.

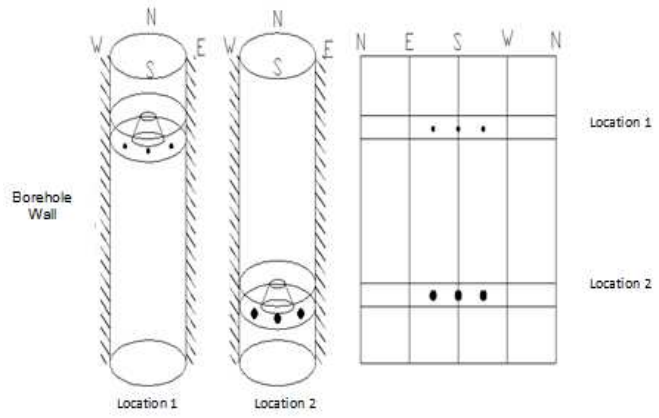

Fig. 1 Schematic diagram of borehole camera imaging.

The RMDI Value

Since the coral reef is a complex entity formed from geological structures of the coral reef, the integrity shown in borehole images or lack thereof depends directly on its geological structures. For instance, a very small number of tiny cavities have little effect on the rock mass integrity, and its image shows even distribution of colours, which is an indication of high integrity; a relatively high number of large cavities break up the rock mass, causing its image to show great variation in colours and signs of fragmentation. We establish a single-variable function that varies along the borehole axial direction, the rock mass integrity index density function (DIDF)[5], represented as f(z) where z is depth, expressed

$$f(\mathrm{z}) = \alpha \tag{1}$$

Where $0 \leq \alpha \leq 1$. If the value of f(z) is 1 or approximating 1, it indicates the rock mass at the given depth has high integrity; the smaller the f(z) value is, the lower the integrity is, and the more fragmented the rock mass appears.

The rock mass integrity index density function DIDF is a reflection of rock mass intactness along borehole axial direction. The rock mass integrity index (RMDI)[5] refers to the proportion of intact rock bodies within a given range, expressed as a percentage, where the given range can be a part of the borehole or the entire depth. If the given depth range is [h1, h2], the RMDI can be expressed as a definite integral of DIDF within the range, expressed as

$$\mathrm{RMDI} = \frac{\int_{h_1}^{h_2} f(\mathrm{z})\mathrm{dz}}{\int_{h_1}^{h_2} 1\mathrm{dz}}. \tag{2}$$

RMDI and Coring Rate Comparative Analysis Method

Due to coral reef structure porous and brittle, low in both hardness and strength, that the pressure easily break the coral reefs during the drilling results in getting incomplete cores. The coring rate is closely related to mechanical disturbance on rock mass, thus we can not determine the integrity simply by the coring rate. RMDI based on borehole camera technique can reduce the drilling mechanical disturbance on rock mass. So it will be more accurate to evaluate the coral reef integrity after considering the RMDI value and the coring rate.

The coring rate is the accumulation of single coral reef core length, however, RMDI value considers the integral effect of rock fragmentation size effect of its density function. If the RMDI value is higher than the coring rate, the coral reef integrity is low and easily broken, because that the relatively complete coral reef is broken after mechanical disturbance results in low or zero coring rate. When the RMDI value is not higher than the coring rate, the coring process has less effect on coral reef integrity. The comprehensive analysis shows that：when the RMDI value is higher than the coring rate, the coral reef integrity is low; otherwise, the coral reef integrity is consistent with the RMDI value.

The example analysis

We take the digital borehole camera date of the South China Sea geological survey as an example and evaluate the coral reef integrity. The coral reef depth tested range 112m from 469m. Through determining the structure types and coral reef integrity block size effect coefficient, we establish the coral reef integrity index density function (DIDF) (refer with: Fig. 2).

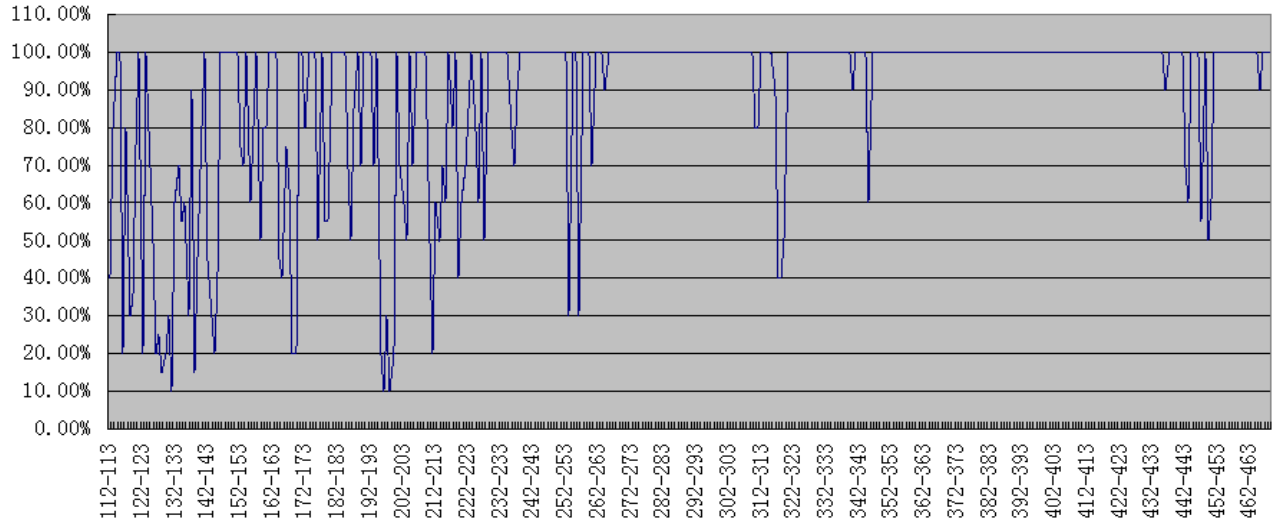

Fig. 2 Coral reef integrity index density function

Then we have a RMDI analysis based on DIDF. According to the research, we select 10m depth scope to evaluate and calculate the RMDI (10m) value. In addition, we compare the RMDI value with the coring rate (refer with: Fig. 3).

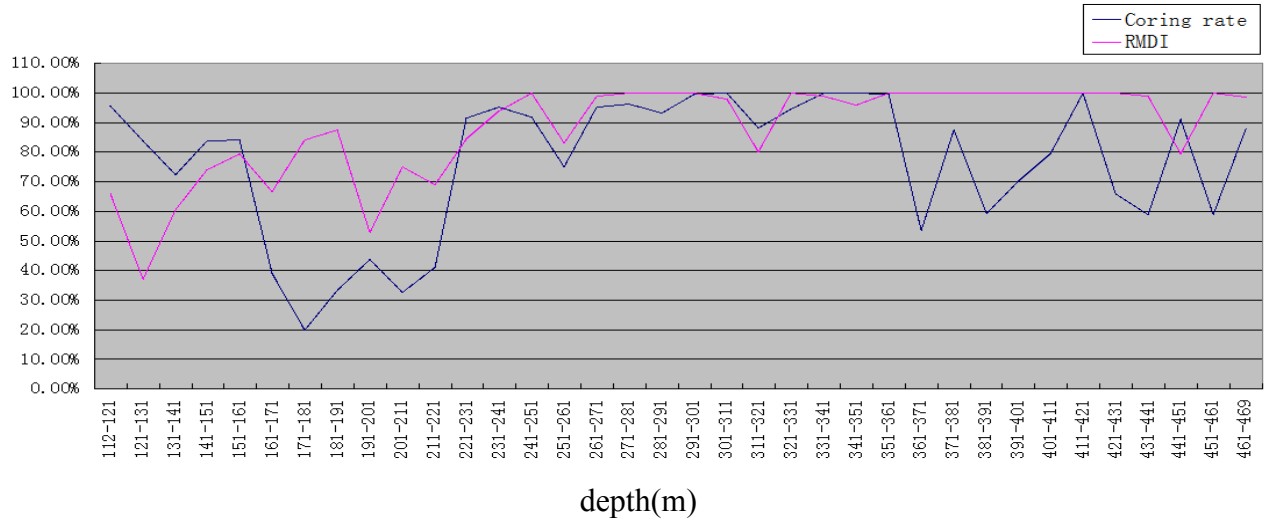

Fig. 3 RMDI and Coring rate

Through the comparative analysis, the coral reef depth in112~151m segment, the RMDI value is less than the coring rate and the RMDI value is between 40%~80%, so the coral reef integrity is general; the coral reef depth in 151~221m segment, the RMDI value is higher than the coring rate, indicating that the coral reef integrity is low; the coral reef depth in 211~351m segment, the RMDI value is nearly equal to the coring rate and the RMDI value is very high, indicating the coral reef integrity is high; the coral reef depth in 351~469m segment, the RMDI value is higher than the coring rate, indicating that the coral reef integrity is low. The coral reef depth from 112m to 469m, the coral reef integrity vary from general to low, form low to high, and then from high to low. It indicates the geological structure of coral reefs is complex. The evaluation is consistent with the actual cores after the comparative analysis.

Summary

This paper proposed the RMDI and coring rate comparative analysis method. Then the evaluation method is applied to the South China Sea some Islands, and the evaluation results prove generally consistent with actual cores. The results indicate that: (1)High-resolution borehole images can provide reliable results for evaluation of coral reef integrity; (2)The RMDI and coring rate comparative analysis method is a feasible approach for the evaluation of coral reef integrity along the full or partial depth of a borehole.

cuitao1203@163.com

Keywords: WZD area; Bauxite; special structure; geological significances

Abstract: Through systematically geologic survey and observation of drills and rock slices this paper have a comprehensive research on special structure of bauxite in Wuchuan -Zheng'an -Daozhen (WZD) area. Special structure mainly includes directional structure of clast, leaching structure and colloid structure. Clast is erratic boulder indicating high energy environment. Leaching structure shows there is an eluvial process in mineralizaton process, and leaching is important for the formation of high grade bauxite. Appearance of colloidal in WZD bauxite shows that agglutinate of gel is one of the reasons for the formation of WZD bauxite. Clastic structure, leaching structure and colloidal structure demonstrate that mineralizaton process of WZD bauxite is a very complicated process.

Introduction

There is abundant bauxite in WZD area. For a long time many experts and scholars have researched on rocks and minerals, chemistry, sedimentary environment, provenance, mineralization age, and mass balance calculation of the bauxite [1-15]. Though there are abundant outcomes of WZD bauxite, analysis on special structure of the bauxite is poor. Through research on special structure this paper has a future understand on metallization and metallogenetic environment of WZD bauxite.

Geological setting

WZD bauxite is located in Wuchuan, Zheng'an and Daozhen County, northern Guizhou, which is an important part of centre Guizhou-southern Chongqing bauxite belt [7]. The regional tectonics position of the study area is in the fold belt in northern Guizhou of the upper Yangtze Block [8]. From the oldest to the youngest, the main strata in WZD area includes Cambrian, Ordovician, Silurian, Permian, Triassic and Jurassic. Cambrian is mainly distributed in the core of anticlines, Triassic and Jurassic are mainly distributed in the core of synclines. Bauxite underlies the LiangShan formation(P2l) or Qixia formation(P2q) in the middle Permian, and overlies the HuangLong formation(C2h) of upper Carboniferous or the Hanjiadian formation of the lower Silurian(S1hj). The bauxite is stratiform and unconformable with the underlying and overlying strata. Fig.1 shows that the distribution of the bauxite is controlled by nine synclines. Thickness of the bauxite is 0.68-15.7m, and its profile can be divided into two lithology parts: the upper part and the lower part. The former is aluminous rock, dominated by high grade bauxite or half grade bauxite; the latter is low grade bauxite. According to the lithological and textural properties, the natural types of bauxite deposit can roughly be subdivided into four categories: massive bauxite, oolithic bauxite, clastic bauxite and earthy bauxite.

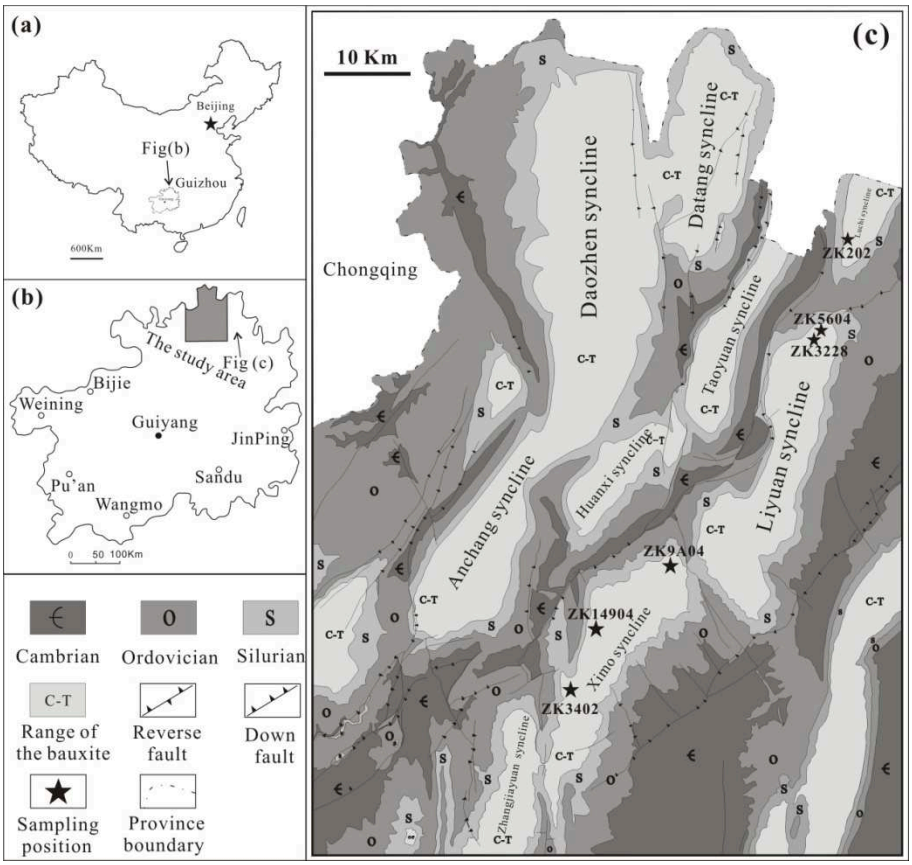

Fig. 1(a)Locality map of Guizhou,(b)The map showing the location of the study area, (c)Geology map of the WZD area in northern Guizhou

Special structure

Fig.1 shows sampling position, hematite, colloidal diaspore, recrystallized diaspore and clastic grain all from different drills. Fig.2 shows main special structure in WZD bauxite. Hematite in Fig.2 is epigenetic, and it is formed in penecontemporaneous period. Hematite indicates oxidation environment. Hematite is veined with a bastard top and a fine bottom (Fig.2, a, b), this special shape is controlled by leaching which is influenced by gravity. Gel bauxite is grey and its shape is like tostromatolite (Fig.2, c). Gel bauxite is formed in pores, and the appearance of gel bauxite indicates that gel deposition is one reason for mineralization of WZD bauxite. Recrystallized diaspora is fusoid with length of 4mm (Fig.2, d). Recrystallized diaspora is different with diaspora in matrix, and it is obviously diaspora recrystallization in pores by leaching in penecontemporaneous period. Clastic grains are black, and some parts of grains have directive property (Fig.2, e, f). Clastic grains can be divided into several groups according directive property. Clastic grain of WZD bauxite reflect features of erratic boulder. Contrast to matrix clastic grain has obviously different component and color, and this shows that clastic grain and matrix are not homochromous deposition. Clastic grain may be deposit later than matrix, grain may be evolved from matrix. Clastic grain and matrix in WZD bauxite demonstrate there may be several streams, and sedimentary environment is not stable. Early Sedimentary deposit may be undergo reform and transform to clastic grain, and then later matrix deposited.

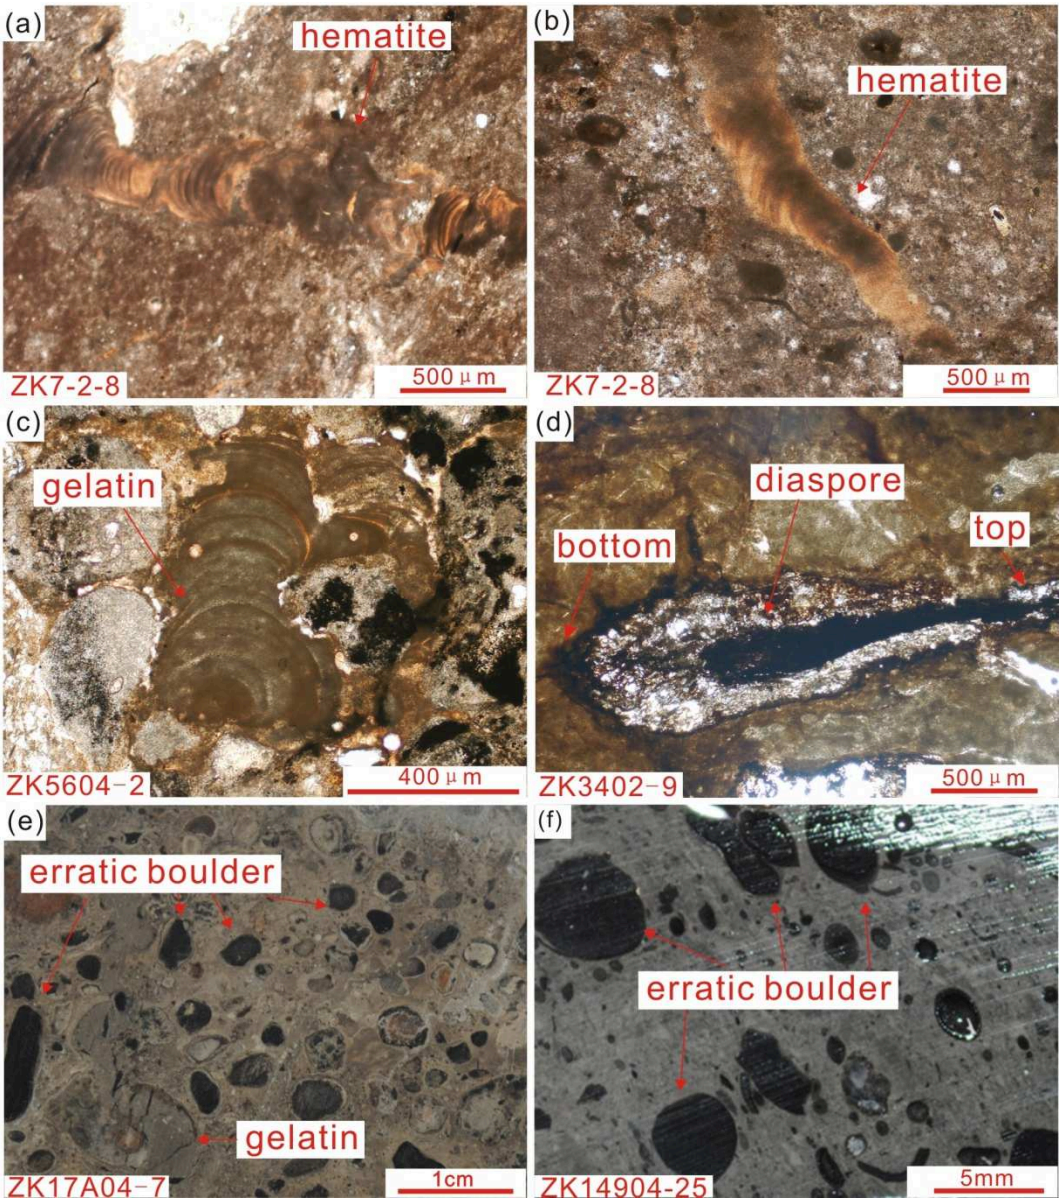

Fig.2 Special structures of WZD bauxite

Discussion

Special structure of bauxite have provide information for the research of mineralization. Hematite present oxidized environment. Generally we think WZD bauxite is formed in a hydrogenant environment, but the appearance of hematite indicates existing an oxidized stage in the process of mineralization. Colloidal structure is universal in bauxite indicating mineralizaton process is not simple mechanical transport. Discovery of erratic boulder shows that hydrodynamic condition is complex, and perimeter of sedimentary basin exist density current. Until now, metallogenetic environment and mineralizaton process are two hard nut to crack, special structure in WZD bauxite further approve it. This work demonstrate mineralizaton process of bauxite is very complicated.

Conclusions

The main conclusions from this study are summarized as follows: 1) Forming process of WZD bauxite is complicated, condense of colloform is one of important factors for the formation of bauxite. 2) Leaching is the key factor for the formation of high grade bauxite. 3) Metallogenetic environment of the WZD bauxite is not remains katakinetomeric and reductive conditions, in the long time of mineralizaton process metallogenetic environment has altered into oxidized and high energy conditions.

Keywords: WZD area; Bauxite; oxidized and reduced conditions

Abstract: Through systematically geologic survey, observation of drills and rock slices and geochemical analysis this paper have a comprehensive research on oxidized and reduced conditions of bauxite in Wuchuan-Zheng'an-Daozhen (WZD) area. The results shows that color, component, lithology and grade of WZD bauxite have vertical alteration; Metallogenetic environment of WZD bauxite in penecontemporaneous period is oxidized, and from top to bottom, oxygen content is gradually decreased; Not only the similar stratigraphic position in different zone of WZD area have different oxygen content, but also identical stratigraphic position in different period has different oxygen content.

Introduction

There is abundant bauxite in WZD area. For a long time many experts and scholars have researched on rocks and minerals, chemistry, sedimentary environment, provenance, mineralization age, and mass balance calculation of the bauxite [1-15].Though there are abundant outcomes of WZD bauxite, analysis on oxidized and reduced conditions in penecontemporaneous period of the bauxite is poor. This paper have a research on oxygen content by analysis on vertical alternation and geochemistry of WZD bauxite.

Geological setting

WZD bauxite is located in Wuchuan, Zheng'an and Daozhen County, northern Guizhou, which is an important part of centre Guizhou-southern Chongqing bauxite belt [7]. The regional tectonics position of the study area is in the fold belt in northern Guizhou of the upper Yangtze Block [8]. From the oldest to the youngest, the main strata in WZD area includes Cambrian, Ordovician, Silurian, Permian, Triassic and Jurassic. Cambrian is mainly distributed in the core of anticlines, Triassic and Jurassic are mainly distributed in the core of synclines. Bauxite underlies the LiangShan formation(P2l) or Qixia formation(P2q) in the middle Permian, and overlies the HuangLong formation(C2h) of upper Carboniferous or the Hanjiadian formation of the lower Silurian(S1hj). The bauxite is stratiform and unconformable with the underlying and overlying strata. Fig.1 shows that the distribution of the bauxite is controlled by nine synclines. Thickness of the bauxite is 0.68-15.7m, and its profile can be divided into two lithology parts: the upper part and the lower part. The former is aluminous rock, dominated by high grade bauxite or half grade bauxite; the latter is low grade bauxite. According to the lithological and textural properties, the natural types of bauxite deposit can roughly be subdivided into four categories: massive bauxite, oolithic bauxite, clastic bauxite and earthy bauxite.

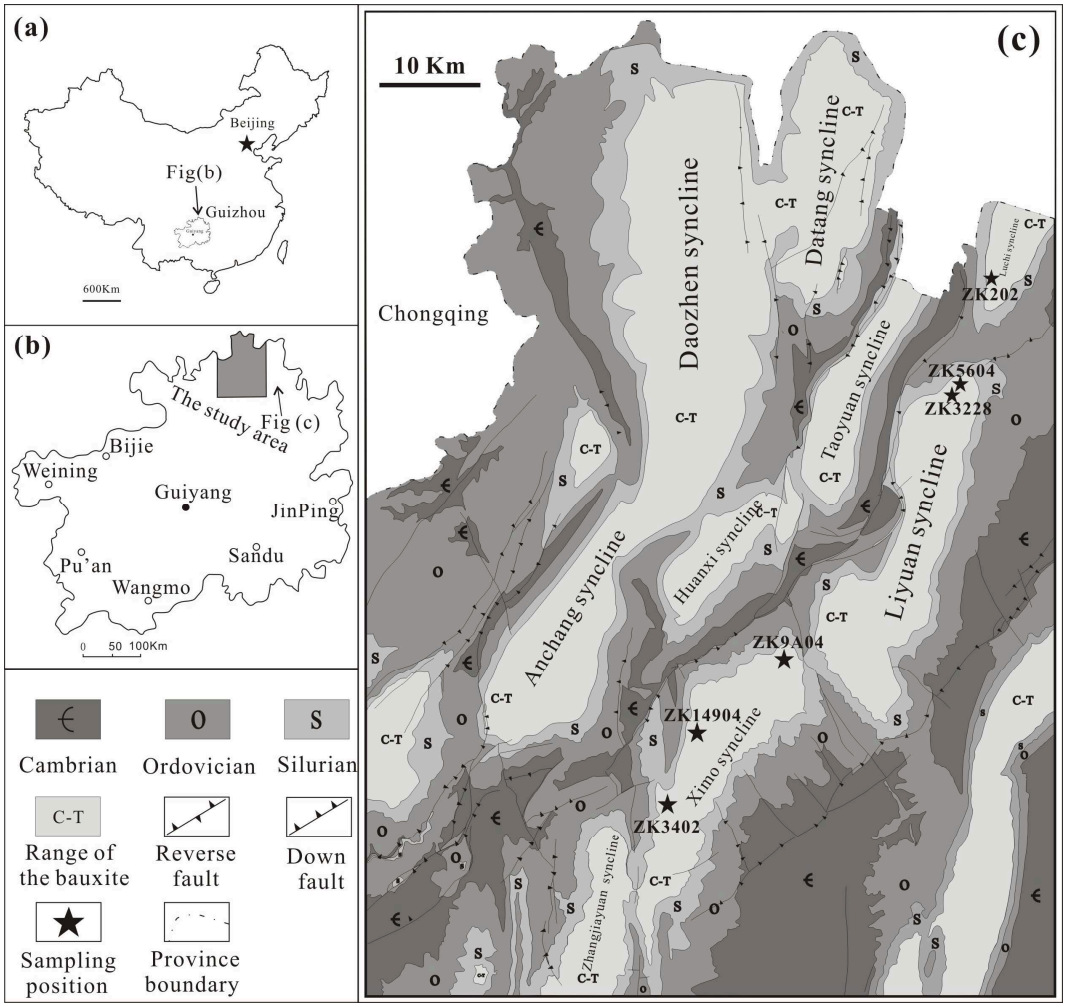

Fig. 1(a)Locality map of Guizhou,(b)The map showing the location of the study area, (c)Geology map of the WZD area in northern Guizhou

Vertical alternations

Fig.2 shows that color of WZD bauxite has obviously vertical alteration, and it can be divided into three parts: upper light parts; middle grey parts; lower dark grey-green parts. Two interface of three parts is usually dark grey indicates there are time break in sedimentary process, and transitional layer is no more than 0.5m (Fig.2). Most of drills in WZD are have this regular pattern, and there are interior vertical regular pattern in three parts. Color regular pattern of WZD bauxite shows that different stratigraphic positions have different oxygen content. Color of bauxite is controlled by component, and light grey bauxite usually is high grade bauxite and dark grey- green bauxite is low grade. In the lower part of profile bauxite is green, and as a matter of fact it is a chlorite rock. For WZD bauxite not only color but also structure are controlled by component, and structure of high grade bauxite is loose than low grade bauxite. Color and structure are bound with grade demonstrates that in penecontemporaneous period metallogenetic environment is oxidized because just in oxidized conditions Fe in bauxite can be removed. The high of grade is , the more white of the bauxite. In other words, in oxidized conditions a great runoff of Fe resulting in the appearance of light grey- white bauxite in WZD area. Except for color, anomaly of Ce reflect oxidized conditions. Positive anomaly of Ce indicates environment is oxidized, there are obviously positive anomaly of Ce in drills of WZD bauxite (Fig.3). Color and positive anomaly of Ce all indicate in penecontemporaneous period metallogenetic environment is oxidized. From top to bottom content of oxygen is decreased because color is deeper in the lower part of bauxite. Appearance of interfaces shows there are several time break in sedimentary process, so in different period oxygen content of the same stratigraphic position is variable. Mineral-formation condition of different zone in WZD area is variable resulting in similar stratigraphic positions have variable oxygen content.

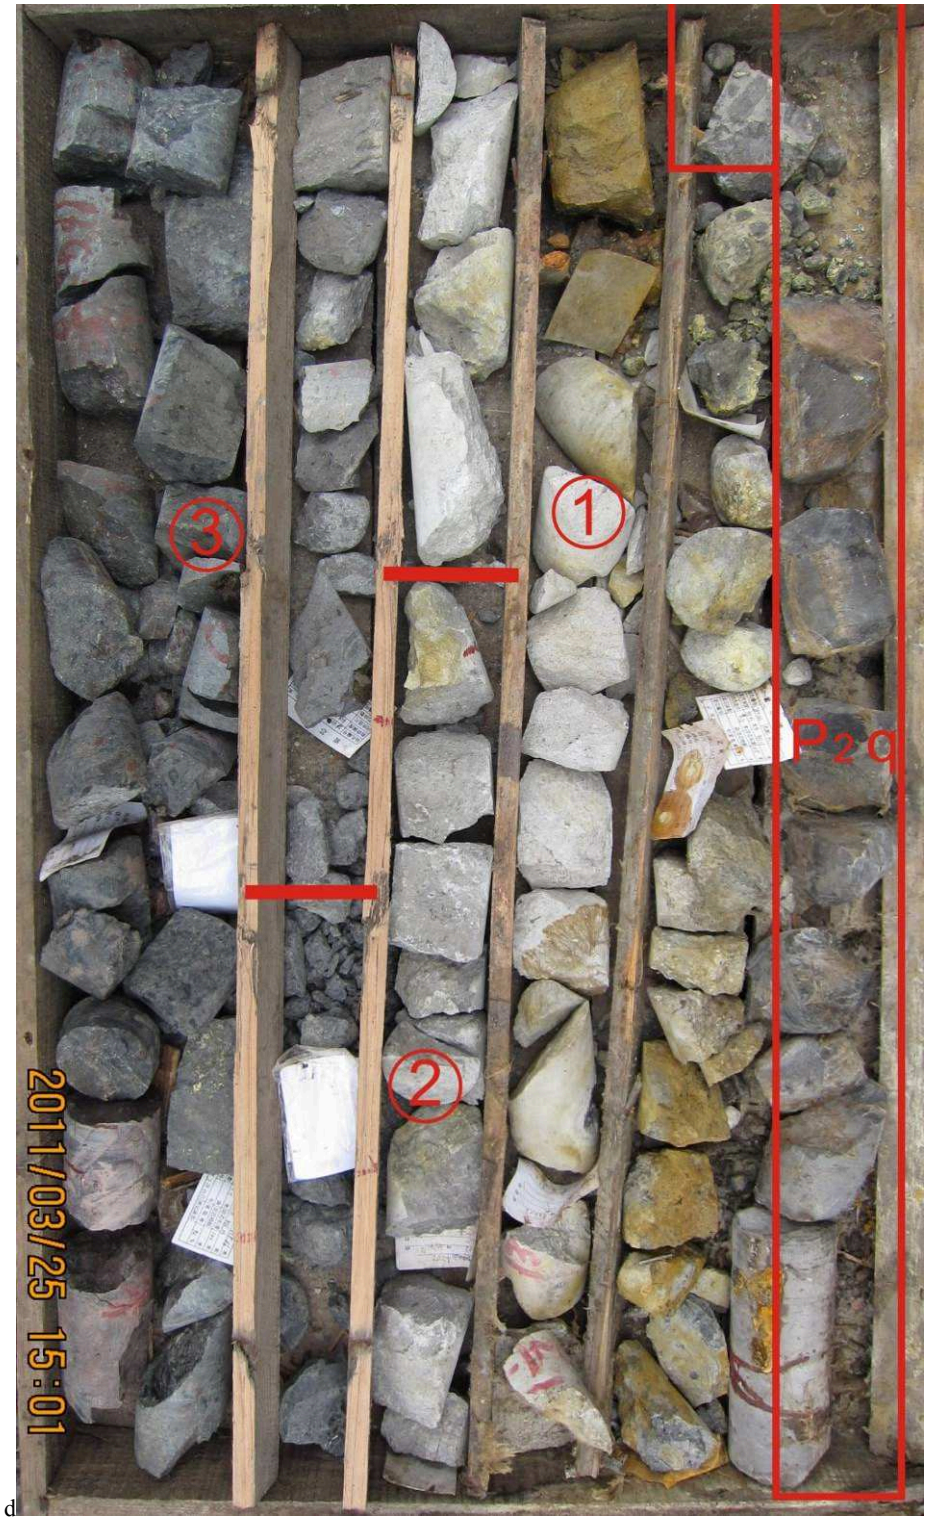

Fig.2 Vertical alteranations of WZD bauxite

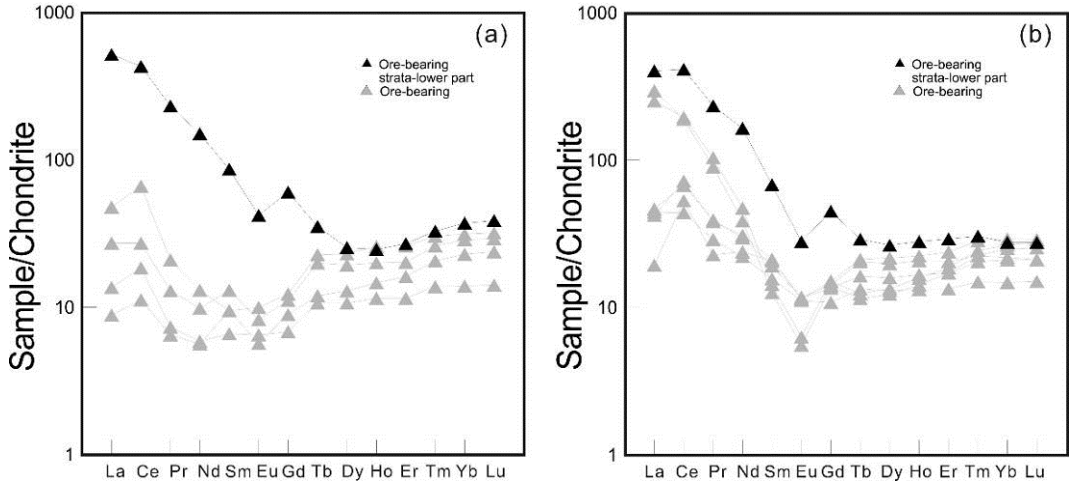

Fig.3 REE distribution patters a. ZK202；b. ZK5604 [9]

Conclusions

The main conclusions from this study are summarized as follows: 1) Metallogenetic environment is oxidized, but oxygen content have a gradually downward decreased trend; 2) Not only the similar stratigraphic position in different zone of WZD area have different oxygen content, but also identical stratigraphic position in different period has different oxygen content because of frequent transgression, regression and leaching process.

Keywords: low-grade; barite; grinding fineness; flotation reagent

Abstract. Beneficiation of a low-grade barite ore assaying 64.32% $BaSO_4$ was conducted by flotation using sodium oleate and sodium silicate. The effect of grinding fineness, type and dosage of flotation reagent in roughing were investigated. Based on the optimum flotation conditions, a close circuit flowsheet was established. Finally, two barite concentrates assaying 96.32% and 91.26% $BaSO_4$ can be obtained at the recovery of 91.94% and 5.25%, respectively, by applying two-time roughing and two-time cleaning operations.

Introduction

The barite resources are very abundant in China, distribute in 26 provinces, and mainly concentrate in the south. Guizhou province alone accounts for a third of the total national's reserves. Hunan and Guangxi rank the second and third in our country, respectively. The barite resources in our country not only have a large reserve, but also have a high grade, $BaSO_4 > 92.8\%$. According to the global mineral statistics released by the American Geological Bureau in January 2013: the reserves of the global barite proven are 240 million tons in 2012 and the barite reserves in China are the most abundant in the world; in 2012, the barite reserves proven in China have reached 100 million tons, accounting for 41.67% of the total reserves of the global barite.

Ore properties. The sample ore taken from Myanmar belongs to a kind of single barite type. The main valuable mineral is barite, the majority of the gangue mineral is quartz, and contains a small amount of aluminosilicate, dolomite, and lapis lazuli. The results of the chemical analysis of the ore are as follows: $BaSO_4$64.32%, $SiO_2$31.21%, $Fe_2O_3$2.65%, MnO0.243%, $Al_2O_3$0.45%, $TiO_2$0.45%, $P_2O_5$0.21%.

Test results and discussion

The type and dosage of collector test. Through grinding fineness analysis, the optimum grinding fineness is set as -200 meshes 80%, so the following tests are conducted under the condition of -200 meshes 80%. Generally speaking, the gravity separation is the main sorting method of the barite ore in the domestic and overseas. Adopting the spiral chute to treat -2mm feed and discarding the tailing in advance, the crude concentrate assaying 65.15% $BaSO_4$ and the tailing assaying 53.23% $BaSO_4$ can be obtained. The increase of the crude concentrate grade is not obvious. This indicates that gravity separation does not apply to the ore, so eventually the flotation flowsheet is adopted. According to the ore properties, initially determine to choose anionic collector—sodium oleate, oxidized paraffin soap and dodecyl benzene xanthate. In order to find out the optimum collector, under the conditions of natural pH of the pulp and sodium silicate (500 g/t), one-time exploratory experiment is carried out on sodium oleate and oxidized paraffin soap and dodecyl benzene xanthate, respectively. This test uses a roughing open-circuit test. The test results are shown in Fig.1, Fig. 2, and Fig.3.

The dosage of oxidized paraffin soap. It can be seen from Fig.1: When the dosage of oxidized paraffin soap is 300 g/t, the grade and recovery of the barite concentrate are 91% and 90%,

respectively. Continue to increase the dosage of oxidized paraffin soap to 400 g/t, the grade and recovery of the concentrate are 87% and 97%, respectively.With the increase of the dosage of oxidized paraffin soap, the concentrate grade decreases and the concentrate recovery increases. It indicates that the selectivity of oxidized paraffin soap is not ideal. When the dosage of oxidized paraffin soap increases, many gangue minerals enter into rough concentrate, leading to the decrease of the concentrate grade.

The dosage of dodecyl benzene xanthate. It can be seen from Fig.2: When the dosage of dodecyl benzene xanthate is 100 g/t, the grade and recovery of the concentrate are 90% and 88%, respectively. Continue to increase the dosage of dodecyl benzene xanthate to 200 g/t, the grade and recovery of the concentrate are 83% and 98%, respectively. This indicates that the selectivity of dodecyl benzene xanthate is poor.

The dosage of sodium oleate. It can be seen from Fig.3: When the dosage of sodium oleate is 600 g/t, the grade and recovery of the concentrate are 91.15% and 92.10%, respectively. Continue to increase the dosage of sodium oleate to 800 g/t, the grade and recovery of the concentrate are 91.70% and 94%, respectively. With the increase of the dosage of sodium oleate, the concentrate grade changes little, but the recovery increases from 92.10% to 94%, indicating that the selectivity of sodium oleate is better.

It can be seen from the above results: using dodecyl benzene xanthate, sodium oleate and oxidized paraffin soap as collectors can obtain the product with the concentrate grade of more than 90% at the recovery of more than 80%, but the collecting effect of sodium oleate is better than other collectors. Therefore, the optimum collector is sodium oleate, and the dosage of sodium oleate is set as 800 g/t.

The type and dosage of inhibitor test. In order to suppress quartz and other gangue minerals, sodium silicate, fluorine sodium silicate and sodium hexametaphosphate are commonly used as inhibitors. The test results indicate that in the same flotation conditions, the inhibitory effect of sodium silicate is better than an equal amount of fluorine sodium silicate and sodium hexametaphosphate, and the grade and recovery of the concentrate obtained are relatively high. So eventually sodium silicate is chosen as the optimum inhibitor.

In order to further explore the optimum dosage of sodium silicate, an explorative experiment about the dosage of sodium silicate is carried out. The results indicate that compared with not adding sodium silicate, adding sodium silicate 500 g/t, the concentrate recovery basically change little, but the concentrate grade obviously increases by 2%. Continue to increase the dosage of sodium silicate to 800 g/t, the concentrate grade continues to increase, but the recovery begins to decrease. It indicates that part of barite is suppressed and along with the gangue mineral into the tailing in the flotation process. Therefore, the optimum dosage of sodium silicate is set as 500 g/t.

Process structure exploration tests. On the basis of the above condition tests, determine two kinds of closed-circuit programs: flowsheet 1 “two-time roughing, one closed cleaning and open in the second cleaning operations”; flowsheet 2 “one-time roughing stage, two-time cleaning stages and one-time scavenging stage” open flotation flow sheet. The closed circuits of flowsheet 1 and 2 are shown in Fig.4 and Fig.5, respectively. In the closed-circuit test of flowsheet 1, two different grade concentrates are obtained namely that chemical grade and weighting agent grade of the barite concentrates, meet different market needs, in order to achieve the maximize economic efficiency. The closed-circuit results of two different programs are shown in Table 1.

Table 1 Closed circuit results of flowsheet1 and 2

Test name	Product	Yield（%）	Grade（%）	Recover（%）
Flowsheet 1	Concentrate 1	64.13	96.32	91.94
	Concentrate 2	3.70	91.26	5.25
	Tailing	35.87	10.36	8.06
	Raw ore	100.00	64.32	100.00
Flowsheet 2	Concentrate	67.33	91.83	93.79
	Tailing	35.87	10.36	8.06
	Raw ore	100.00	64.32	100.00

It can be seen from Table 1: In flowsheet 1, the recoveries of concentrate 1 and 2 reach to 97.19% at the comprehensive grade up to 92.16%. In flowsheet 2, the barite concentrate with the grade of 91.83% at the recovery of 93.79% is obtained.

Under the condition of same jobs of two flowsheet: flowsheet 1 has a better comprehensive recovery, a better floatation index, less return of middling, and a stronger practical operability. So eventually adopt flowsheet 1, and mass balance of flowsheet 1 is shown in Figure 6.

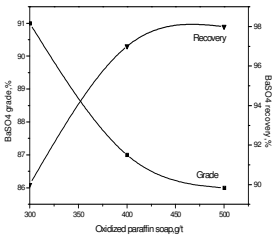

Fig.1: Results of oxidized paraffin soap test

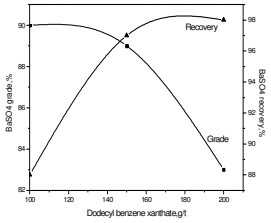

Fig.2: Results of dodecyl benzene xanthate test

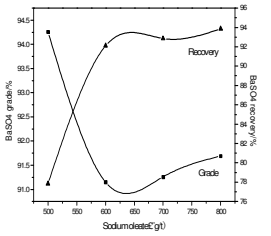

Fig.3:Results of sodium oleate test

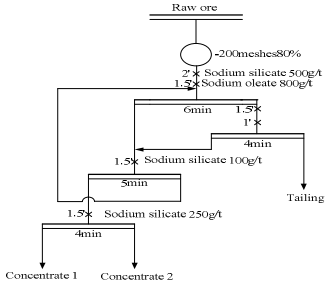

Fig.4 Flowsheet 1

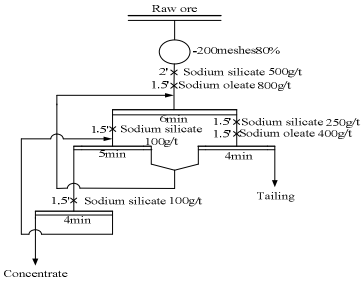

Fig.5 Flowsheet 2

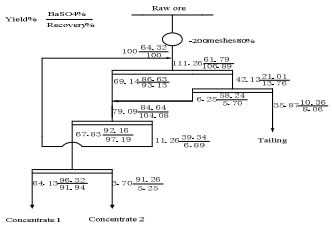

Fig.6 Mass balanceof flowsheet 1

Summary

The barite ore taken from a barite mine in Myanmar belongs to a kind of single barite type and easy to be treated. The barite can be recovered by a simple flotation flow sheet, two-time roughing, one closed cleaning and open in the second cleaning operations. The optimum flotation conditions are sodium oleate 800g / t and sodium silicate 500 g / t at the grinding fineness -200 meshes 80% and two kinds of high-quality barite concentrates can be obtained, which meet the quality standard of barite product.

Keywords: Flotation, Copper-nickle ore, New nickel inhibitor, YS

Abstract. Effect of grinding fineness and inhibitors on mixed flotation of low copper and nickel were studied and a new nickel inhibitor YS was used in the process of separation of copper and nickel. The results indicated that the high-quality mixed concentrate with the recoveries of Cu and Ni 76% and 65.6% and the grade of Cu and Ni were 4.66% and 4.3%, respectively, was got under the condition of sodium silicate (200 g/t), CMC (200 g/t), copper sulphate200 g/t, amyl xanthate 100 g/t and pine oil 30 g/t with the grinding fineness of -0.074mm80%. Then, Qualified Cu concentrate with the grade26.65% and recovery 55.62%, Qualified Ni concentrate with the grade26.65% and recovery 55.62%, respectively, were got by using the new nickel inhibitor YS in the separation flotation of copper and nickel.

Introduction

As we all know there are three types nickel deposit in the world: nickel sulfide ore, laterite nickel ore and nickel silicate deposit. The nickel sulfide ore will still be an important source of nickel, from which the extract of nickel accounted for about two-thirds of the total nickel production at present [1, 2]. The copper and nickel sulfide ore is the main nicke sulfide ore whose mineralogical properties are similar, that include pyrrhotite, pentlandite and chalcopyrite. In the practice of the flotation, chalcopyrite, most pentlandite and purple sulfur nickel can be quickly floated out, while little pyrrhotite and purple sulfur nickel float slowly [3].

In addition, most of the copper and nickel sulfide ore has the following characteristic: The dissemination particle sizes of sulfide mineral are uneven; Nickel sulfide minerals are easily over crushed and oxidized; Natural flotability of nickel sulfide are similar to those of pyrites; Some useful minerals are magnetic, such as magnetic pyrite, purple sulfur nickel; Gangue mineral easy to be muddy and so on. The flotation of copper-nickel ore has been a worldwide difficult problem because of the so much complicated nature. Therefore, the highly efficient recovery of copper and nickel is worth studying [4, 5].In this study, a new inhibitor YS with higher efficiency and better selectivity is used in the separation flotation of copper-nickle in the alkali conditions.

Experimental

Material

In this study, sodium carbonate, amyl xanthate, sodium silicate and CMC from Zhuzhou Flotation Reagents Co.,Ltd with industrial purity are used. Copper sulfate from Tianjin NO.3 Chemical reagent factory with chemical purity is used as activator. YS from Kunming University of Science and Technology with industrial purity is used as nickel inhibitor. Lime from Tianjin NO.3

Chemical reagent factory with chemical purity is used as depressor and pH regulator. Tap water in laboratory is used in the flotation tests.

The material used in the present investigation was from the Yunnan province, with the chemical composition and titanium phase analysis as illustrated in Tables 1, 2 and 3, respectively. From Table 1, the material is a typically low-grade copper and nickel ore, with the contents of recoverable Cu and Ni elements as low as 0.38% and 0.57%, respectively; the dominant gangue element in the material is silica with a content of 40.04%. From Table 2 and 3, copper sulphide and combined copper oxide are determined as the Cu bearing minerals. Nickel sulfide and Nickel silicate are determined as the Cu bearing minerals.

Table 1 The chemical compositions of the ore sample （mass fraction,%）

Distribution /%	0.1	0.44	1.78	97.68	100

Flotation test

The rougher flotation of copper and nickel sulfide ore was conditioned for 3 minutes while a given amount of inhibitor was added at first. After that, the conditioning continued for 2 minutes with activator, 1 minute with collector and 1 minute pine oil, respectively. The products were dried and weighed, and then were chemically analyzed for zinc and indium.

Result and discussion

Mixed flotation of copper and nickel

1)Effect of grinding fineness

Grinding fineness is one of the key factors influencing the recovery. Over grinding is too easy to cause new argillization. Less grinding can lead to the useful minerals not dissociation. So the grinding fineness is studied. Figure 1 illustrates the concentrate grade and recovery of Cu and Ni from the rougher flotation of low-grade copper and nickel ore as the different grinding fineness By using the inhibitor sodium carbonate (200 g/t) and CMC (200 g/t), 200 g/t activator copper sulphate, 100 g/t collector amyl xanthate and 30 g/t pine oil, respectively.

As it noted, the Cu and Ni recoveries increased as the increase of grinding fineness until it reached the plateaus at the critical fineness. While, the grades increased maximum and then decreased with the increasing grinding fineness. Recovery is usually must be considered first in the rougher flotation. The optimum grinding fineness was -0.074mm 80%, while the Cu grade was 4.66% and the recovery was 76% in the rougher flotation, respectively, Compared, the Ni grade and recovery was 4.3% and 55.6%, respectively.

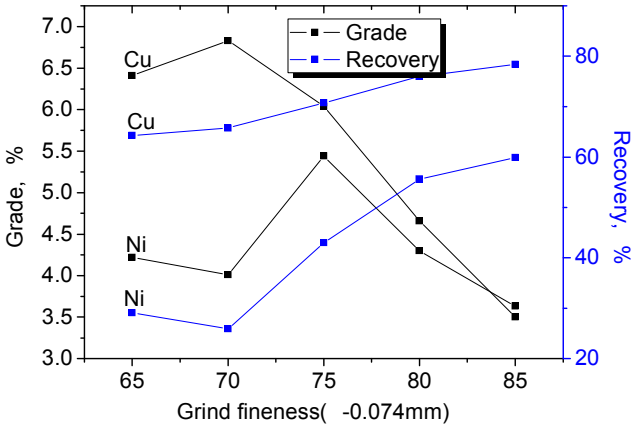

Fig.1 Effect of activator dosage on the concentrate grades and recoveries of Cu and Ni from the rougher flotation.

2) Effect of inhibitors

Inhibitors can block or reduce the speed of chemical reaction. The flotation with the dosage of copper sulfate 200 g/t, amyl xanthate 100 g/t, pine oil 30 g/t and different inhibitors was studied.

Results of sodium carbonate and CMC or sodium silicate and CMC used as inhibitors are shown in Fig.2. The optimum mixed concentrate was got when sodium silicate and CMC were used as inhibitors, with the recovery of recoverable Cu and Ni elements as high as 76% and 65.6%, respectively, while the grade of recoverable Cu and Ni were 4.66% and 4.3%, respectively. Compared the results of sodium carbonate and CMC were used as inhibitors, though the grade of Cu and Ni were reduced 1% and 0.7%, the recoveries increased 1.5% and 19.5%.

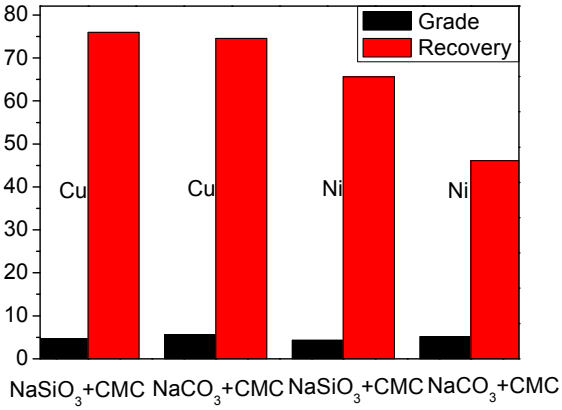

Fig.2 Effect of inhibitors on the concentrate grades and recoveries of Cu and Ni from the rougher flotation.

Separation flotation of copper and nickel

The mixed concentrate was removed reagent with the addition of500 g/t activated carbon. Then the pH value was adjusted by 2 kg/t lime. The effect of the new nickel inhibitor YS on the separation of copper and nickel was studied and the results are illustrated in Fig.3.

As it noted, the Cu and Ni recoveries increased maximum and then decreased with increasing of the dosage of YS. But the grades of them were changed a little. The optimum dosage of YS was 5 g/t with the grade of Cu and Ni were 26.65% and 3.8%, the recoveris was 55.62% and 55.3% in the separation flotation, respectively. Obviously, the inhibition of the new mixed reagent YS was stronger on the flotation of nickel and weaker on copper in the alkali conditions.

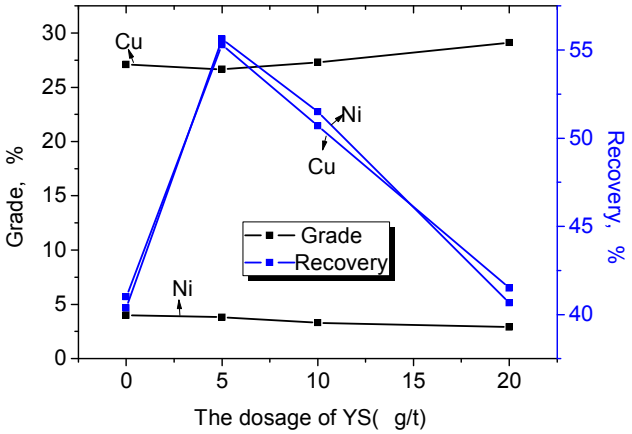

Fig.3. Effect of YS on the concentrate grades and recoveries of zinc and indium from the rougher flotation.

Conclusions

The conclusions were made as a result of this experimental study carried on copper and nickel ore in Yunnan Province of China.

High-quality mixed concentrate with the recoveries of Cu and Ni 76% and 65.6% and the grade of Cu and Ni were 4.66% and 4.3%, respectively, was got under the condition of sodium silicate (200 g/t), CMC (200 g/t), copper sulphate200 g/t, amyl xanthate 100 g/t and pine oil 30 g/t with the grinding fineness of -0.074mm80%.

Qualified Cu concentrate with the grade26.65% and recovery 55.62%, Qualified Ni concentrate with the grade26.65% and recovery 55.62%, respectively, were got by using the new nickel inhibitor YS in the separation flotation of copper and nickel.

Keywords: Coal; Jurassic; Distribution; Cr; Pb; Zn

Abstract. The concentration and distribution of Cr, Pb and Zn in 22 Jurassic coals from northern Shaanxi,and Ningxi, China were studied. The samples were collected from eight coal mines of five different region, including Yuyang Region, Hengshan, Shenmu, Huangling and Lingwu. Comparing with Chinese coals, American coals and coal Clarke value: Pb showed different degree enrichment in the study region except Ningxia ; Cr was enriched in Shenmu coals, Huangling coals and Hengshan coals; whereas the content of Zn in the study region coals was lower than in American coals. Horizontal variation of the three elements in the study region indicated that different elements showed different variation trend. Based on statistical analyses, Pb showed a moderate relationship with ash yield, whereas Cr had a high correlation coefficients with total sulfur.

1 Introduction

Cr, Pb and Zn are the trace elements of environmental concern. Their environmental impact is related with their concentration, toxicity and modes of occurrence in coals[1][2].The elements concentration in coals is related to coal peat-swamp environments, geological processes during deposition and post-deposition, as well as the properties of coal bedrocks[3]. The elements in coals may be concentrated in organic matter, or in inorganic matter, such as in silicates, carbonates or sulphates minerals. At sometimes, the elements may been not only associated with organic matter, but also with inorganic matter.

There are many publications that have reported the elements concentration, distribution and origin in different coals[1][4][5][6].But, most publications paid attention to the districts where the elements are anomalous enriched. Moreover, the number of samples analyzed was limited.

There are huge coal resource in northern Shaanxi, and Lingwu, Ningxia. The coal is Jurassic bituminous coal, with low sulfur content, low ash yield and high calorific. The coal is mined mainly for power generation. There is little knowledge about the concentration and distribution of trace elements in the places. Therefore, it is essential to understand the abundances and distribution of trace elements in these places.

2 Experimental

2.1 Instrumentation and reagent

Microwave assisted extraction was conducted using a MDS-8 microwave oven (from Shanghai Sino Instruments in China) with polytetrafluoroethene extraction vessels. The temperature and pressure were monitored in a control vessel by an armored fiber-optic temperature and pressure control probe. The concentration of Cr, Pd and Zn were determined by AAS-6100 atomic absorption spectrometer(Shimadzu Instrument in Japan). The coal ash yield was analyzed by HTGF-3000 instrument (made in Hebi, Henan, China). The sulfur concentration in coals was determined using sulfur tester(made in Shanghai, China).

H_20_2 is analytical reagent without further purification. HNO_3 and HF are all the guaranteed reagent. The solutions were prepared using ultrapure water passed through a ultrapure water purification system(made in Nanjing, China)

2.2 Coal sample

Coal samples were obtained from seven coal mine of northern Shaanxi and one coal mine of lingwu. Before the experiment and analysis, all coal samples were ground by a high speed crusher, sieved through a 200-screen, and kept into pre-cleaned glass bottles at room temperature for subsequent analyses.

2.3 Sample treatment

For each run coal sample of about 0.1g(±0.0001g) was dissolved into 8 mL HNO_3, 2 mL H_20_2 and 1 mL HF on a microwave digestion system. The digestion was conducted under 8MPa for 50 min at 100-180°C , and 9 MPa for 10 min at 200°C. After 0.1 g sample was dissolved, it was made up to 50 mL with ultrapure water for AAS analysis.

3 Result and discussion

3.1 Content of elements in Yuyang Region coals

Yushuwan(YSW) coal mine was located in Yuyang Region, Yulin, Shaanxi, China. Only three samples from the coal mine were collected and analyzed. The contents of Cr, Pb and Zn in the coals were showed in Table 1. Table 2 listed ranges and arithmetic mean(AM) of concentration of Cr, Pb and Zn in Chinese coals ,which are Middle Jurassic coals from Shanxi, and in USA coals. The table 2 also included coal Clarke value of Cr, Pb and Zn.

Table 1 The content of elements and ash yield in Yushuwan coals

Sample	Cr(ppm)	Pb(ppm)	Zn(ppm)	St,d(%)	*Ad*(%)
YSW1	1.66	82.66	34.63	0.63	17.88
YSW2	24.81	64.54	65.61	0.34	3.25
YSW3	14.71	51.07	20.96	0.50	9.12
AM	13.73	66.09	40.40	0.49	10.08

Comparing YSW coal with coal Clarke value, we concluded that Pb(up to 7.34×) was strong enriched, Zn (up to 1.44×) showed a moderate enrichment, and Cr had no enrichment. As compared to USA coal, only Pb (up to 6.01×) showed a high enrichment. YSW coals were located in Yan'an Formation coal-bearing strata. Compared with Middle Jurassic coals in Shanxi, the three elements(1.7- 7.03×) showed a certain degree of enrichment.

Table 2 The content and range of elements in Chinese coals and American coals , as well as coal Clarke value(ppm)

Element	Chinese coal[7]		American coal[8]		Clarke[9]
	Range	AM	Range	AM	AM
Cr	2.2-19.4	7.2	0.25-43	14	17
Pb	Bdl-30.0	9.4	0.3-590	11	9.0
Zn	Bdl-64.1	23.7	0.85-5100	53	28

Bdl: below detection limit;

3.2 Content of elements in Ningxia coals

The coal samples were collected from Lingwu, Ningxia(NX), China. NX coals were located in the Third Member of Jurassic Yan'an Formation, and named No. 2 coals of Yan'an Formation. The three samples of NX coals were analyzed , and the results were listed in Table 3.

In NX coals , only Pb had a similar value with coal Clarke value, whereas the content of Cr and Zn were lower than coal Clarke value. The content of the three elements in NX coals were lower than in American coals. As compared with Jurassic coals in China, only Cr (up to 1.78×) showed a moderate enrichment in NX coals.

Table 3 The content of elements and ash yield in lingwu coals

Sample	Cr(ppm)	Pb(ppm)	Zn(ppm)	St,d(%)	*Ad*(%)
NX1	8.03	14.84	16.57	0	3.1
NX2	6.63	2.76	14.13	0	2.57
NX3	23.72	11.59	6.98	0.33	3.61
AM	12.79	9.73	12.56	0.11	3.09

3.3 Content of elements in Shenmu coals

Shenmu has huge coal resource. Zhangjiamao (ZJM) coal mine was located in Shenmu, Shaanxi, China. Only one sample from Shenmu was collected and analyzed. The content of the three elements were listed in Table 4.

A comparison of content of the three elements in ZJM coal with coal Clarke value indicated that the three elements showed a certain degree of enrichment, and Pb (up to 2.17×) had the higher

enrichment than Cr and Zn. Comparing with American coals, Cr showed higher enrichment than Pb in ZJM coals, and Zn content was lower than coal Clarke value. As compared with Jurassic coals, the three elements showed enrichment in ZJM coals. Cr(up to 1.78×) and Pb(up to 2.09×) were strongly enriched, and Zn(up to 1.89×) showed a moderate enrichment.

Table 4 The content of elements and ash yield in Zhangjiamao coal

Sample	Cr(ppm)	Pb(ppm)	Zn(ppm)	St,d(%)	Ad(%)
ZJM	29.16	19.49	44.94	0.52	4.74

3.4 Content of elements in Huangling coals

Huangling(HL) coal mine was located in Huangling, Yan'an, Shaanxi, China. Six samples were collected and analyzed from HL coal mine. As compared with Chinese coals, American coals and coal Clarke value, Cr and Pb were enriched, and Zn showed no enrichment.

3.5 Content of elements in Hengshan coals

Nine samples were collected from four coal mines in Hengshan, Yulin, Shaanxi, China, including Shimawan (SMW) , Gaoxingzhuang (GXZ), Fanhe (FH) and Changgou(CG) coal mine. The coal beds in the four coal mines were deposited in No.3 coal seam of the Second Member of Jurassic Yan'an Formation. As compared with Chinese coals, American coals and coal Clarke value, Cr(2.65-6.25×) and Pb(2.77-3.38×) were strongly enriched, and Zn showed no enrichment.

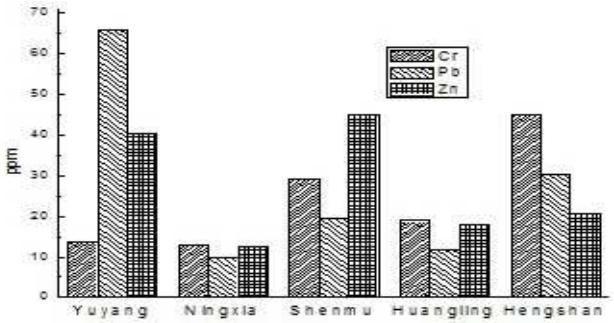

Fig. 1 Stacked bar plot of trace element contents in different district

3.5 Horizontal variation of content of the elements

In the study regions, the content variation of the trace elements was showed in Fig.1. From it, we can see that the highest content of Cr was in Hengshan coals, for Pb in Yuyang coals and for Zn in Shenmu coals. The lowest contents of three elements were in Ningxia coals. Ningxia coals had the lowest level of dry base total sulfur(0.11%) and dry base ash yield(3.09%). It may be the reason that the lowest content of the trace elements was in Ningxia coals.

Table 5 The content of elements and ash yield in Huangling coals

Sample	Cr(ppm)	Pb(ppm)	Zn(ppm)	St,d(%)	Ad(%)
HL1	21.39	13.91	28.16	0.48	3.23
HL2	7.72	13.91	23.08	0.54	5.59
HL3	22.33	5.55	19.73	0.36	6.29
HL4	22.95	6.02	11.38	0.48	3.56
HL5	31.03	25.06	6.75	0.8	10.24
HL6	8.18	6.48	18.31	0.49	6.19
AM	18.93	11.82	17.90	0.53	5.85

Table 6 The content of elements and ash yield in Hengshan coals

Sample	Cr(ppm)	Pb(ppm)	Zn(ppm)	St,d(%)	Ad(%)
SMW1	27.61	74.30	34.05	1.73	6.69
SMW2	12.69	30.63	28.07	1.812	4.66
SWM3	41.6	48.29	49.05	1.54	6.59
GXZ1	13.78	3.694	14.14	1.3	6.3
GXZ2	7.41	2.30	23.07	0.81	3.3
FH1	133.28	25.99	7.21	3.76	5.78
FH2	123.65	56.18	1.03	5.42	10.36
FH3	13.62	18.56	19.31	1.98	6.32
CG1	31.65	14.38	8.86	3.59	14.37
AM	45.03	30.48	20.53	2.44	7.15

3.6 Association of trace element content with ash yield

The relationships between trace element content and ash yield was used to conclude trace elements association with the mineral in coals. The Fig. 2 showed the relationship between the element content and ash yield in different coals. The ash yield of coals in this study area ranged from 2.57% to 17.88%, with an average of 6.53%. The coals in this study area were low ash coals. The correlation coefficients of Pb contents with ash yield was 0.499. It indicated that Pb had a moderate association with inorganic matter. The content of Cr (0.122) and Zn (-0.139) had lower correlation coefficients with ash yield than Pb. This indicated that the two elements had lesser inorganic but more organic affinity. Total sulfur content had a low correlation coefficient (0.397) with ash yield. It showed that organic sulfur dominated in the study area coals. Cr had relatively high positive correlation

coefficient (0.804)with the total sulfur. We can concluded that Cr may been mainly related with organic matter, especially organic sulfur functional group.

4 Conclusions

The concentration of three elements from different places in the study area varied greatly. Comparing with Chinese coals, American coals and coal Clarke value, Pb showed different degree enrichment in the study area except Ningxia. As comparison with Chinese coals, American coals and coal Clarke value,Cr was enriched in Shenmu coals, Huangling coals and Hengshan coals. The content of Zn in the study area was lower than in American coals. Compared with Chinese coals, only Yuyang coals and Shenmu coals displayed higher content of Zn.

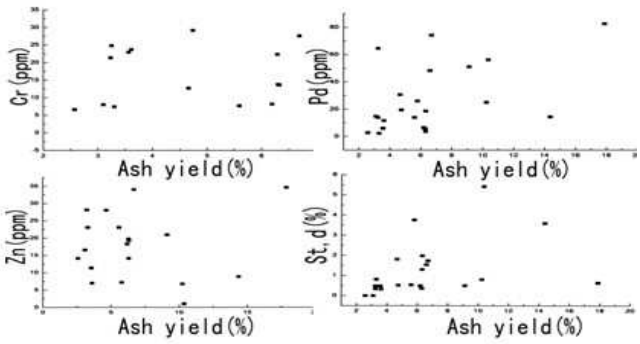

Fig.2 The relationship between content of elements and ash yield

The highest content of Cr was in Hengshan coals, for Pb in Yuyang coals, and for Zn in Shenmu coals. The lowest content of the three elements was in Ningxia coals.

In the study area, the content of Cr and Zn were not clearly related with ash yield. Pb had a moderate relationship with ash yield, while Cr had a high correlation coefficients with total sulfur.

Keywords: Water Level Changes, Channel Capacity, Ship Loading Rate, Impact

Abstract. Water level determines channel capacity, in order to protect the safety of navigation and give full play to the advantages of shipping, the paper analyzes the relationship between the draft and loading rate of various types of ships, and proposed the quantitative model of impact of water level changes on channel capacity, the results showed: small ships are less affected by water level changes, and large ships are great affected by water level changes, the actual amount of cargo related the ship design parameters, this article has a certain reference value for navigation management and planning.

Introduction

Channel capacity usually refers to certain grades and standards of channel. Under certain environmental conditions of navigation, channel can navigate the largest scale, the largest DWT of ships and the quantity of ships flow[1]. Water level is not only the primary condition for safe navigation, but also one of the main factors that affect on channel capacity. With the rapid development of the inland river construction, water level and ship types have a significant change, it is necessary to study the relationship between water level and channel capacity.

The Relationship between Water Level and Water Depth

In fact, the concept of water level is different from water depth. Water depth is the vertical distance from water surface to the bottom of the river, and water level is the vertical distance from water surface to the reference plane, and now the data of hydrological observations are based on water level, can convert water level into water depth by a certain formula (actual water depth = graphical representation of water ship± the value of water level) .

Relationship between Water Depth and Channel Capacity

Water depth of channel directly affects the channel capacity. while at the same channel, different points, different lines and different sections, the water depth is not the same, in order to ensure the safety of navigation, should be considered the minimum water depth at the ship route. Relationship between the draft of ship and water depth of channel can be expressed as[2][3]:

$$H = T + \Delta h \tag{1}$$

In this formula, H is the minimum water depth of channel; T is the draft of ship; and Δh is the additional water depth of the channel, it means that the height from the bottom of the ship to the bottom of the channel. The unit is m.

If a ship wants to navigate at a certain grade of channel, water depth of channel should ensure that the ship has the additional water depth for safe navigation in the draft, the ship can be adjusted cargo capacity to change the draft in order to accommodate water depth of the channel. The additional water depth of different grades of channel are different.

Relationship between Water Depth and Ship Loading Rate

1）Ship loading rate. Ship loading rate is the ratio of the actual load capacity to the design load capacity of the ship. In ensuring safe navigation and do not overload, the higher loading rate, the stronger shipping capacity, and the better benefits. Ship loading rate can be extrapolated by ship displacement formula.

$$\Delta_0 = L_c BTc_b \tag{2}$$

In this formula, Δ_0 is displacement when the ship has the design load, the unit is t; L_c is length of the ship, the unit is m; B is breadth of the ship, the unit is m; T is the largest draft when ship has the design load, the unit is m; and c_b is block coefficient which is different from different ships.

Length, width and block coefficient of the ship is constant, so displacement of the ship and the draft presented exist in a direct proportion relationship. When the displacement changes, the draft will occur in direct proportion changes .

$$\frac{\Delta}{\Delta_0} = \frac{T_s}{T} = \frac{W_o + W_e}{W_o + W} \tag{3}$$

T_s :Actual draft of the ship, the unit is m.

Loading rate of ship can be expressed as:

$$\varepsilon = \frac{W_e}{W} = \frac{(W_o + W)}{WT} T_s - \frac{W_o}{W} \tag{4}$$

The maximum load capacity, the maximum draft and ship weight are related with ship types, they all are constant, so loading rate of ship is a function of actual draft. The actual draft of the ship can be expressed as:

$$T_s = \min(H - \Delta h,\ T) \tag{5}$$

The design draft is a constant when ship is certain, loading rate of ship can be expressed as:

$$\varepsilon = \frac{(W_o + W)}{WT} \min(H - \Delta h,\ T) - \frac{W_o}{W} \tag{6}$$

If $a = \frac{(W_o + W)}{WT}$, $b = \frac{W_o}{W}$, a and b are constant, the above formula can be simplified to:

$$\varepsilon = f(T_s) = a \min(H - \Delta h,\ T) - b \tag{7}$$

Impact of water level changes on loading rate of ship needs to be studied from two aspects. One is water depth changes of channel; the second is the adaptational degree of ship types for water level changes.

2) The quantitative model of impact of water level changes on ship loading rate. Assuming ship will load shedding when water level will not ensure the additional water depth of the channel for sage navigation. Maximum load of ship depends on the minimum water depth of navigation route, the ship will not be loaded that means the loss of capacity. H_1 and H_2 respectively represents two channel's water depth conditions, and $H_1 > H_2$. Water depth of channel reduced from H_1 to H_2.

There are three situations with the relationship between the two channel's water depth and the additional water depth. The first situation is $\Delta h < H_2 < H_1$; the second one is $H_2 < \Delta h < H_1$, and the last one is $H_2 < H_1 < \Delta h$. Different water depths represent different navigation conditions. Different ship types have different degree of sensitivity to water level changes.

(1) The first situation is $\Delta h < H_2 < H_1$. According to this water depth, to build a conceptual model between water depth and the draft of all types of ships. As shown in Fig 1.

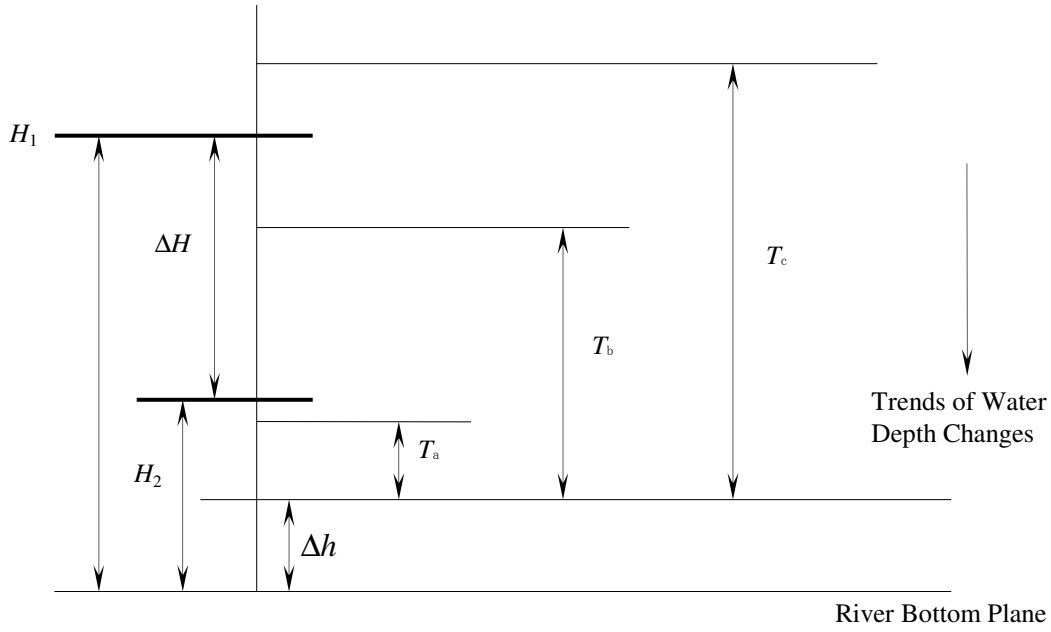

Fig.1 A Conceptual Model between Water Depth and the Draft of all Types of Ships(1)

H_1 :The first water depth condition, the unit is m;

H_2: The second water depth condition, and $H_1 > H_2$, the unit is m;

ΔH :Water depth variation, namely H_1 - H_2, the unit is m;

Δh : The additional water depth of a certain grade channel, the unit is m;

T_a, T_b, T_c :the draft of a, b, c types of ship, namely the design draft, the unit is m.

In this water depth condition, ships are divided into three types:

①Type A:The seaworthy water depth of type A ships is $T_a+\Delta h$ when it is full load, and $T_a+\Delta h \leqslant H_2$, it shows that water depth changes has no effect on its cargo capacity, ship type A can be fully loaded before and after changes in the water level.

②Type B:The seaworthy water depth of type B ships is $T_b+\Delta h$ when it full load, and $H_2<T_b+\Delta h \leqslant H_1$, it shows that water depth changes has some effect on its cargo capacity, the first condition of water depth can achieve full load, the ship's draft is T_b, and $\varepsilon_{b_1} = 100\%$; but water depth reduces from H_1 to H_2 ,the ship should load shedding for ensuring safe navigation, maximum draft should reduce to H_2-Δh , at this time, loading rate changes into $\varepsilon_{b_2} = a(H_2\text{-}\Delta h) - b$.

③Type C:The seaworthy water depth of type C ships is $T_c+\Delta h$ when it is full load, and $T_c+\Delta h > H_1$, it shows that both water depth conditions all can't achieve full load. When water depth is H_1, the loading rate is $\varepsilon_{c_1} = a(H_1\text{-}\Delta h) - b$; when water depth changes into H_2, the loading rate will reduce to $\varepsilon_{c_2} = a(H_2\text{-}\Delta h) - b$. Loading rate of type C ships is affected by water level changes. Change amount of loading rate can manifest as $\Delta\varepsilon_c = a\Delta H$.

Based on the above analysis, water depth changes affects loading rate of ships, this effect related to the draft when ship is full load. In two different water depth conditions, there are three different change patterns of ship's loading rate, mathematical models shows that:

$$\begin{cases} T+\Delta h \le H_2, \begin{cases} \varepsilon_1=100\% \\ \varepsilon_2=100\%; \end{cases} \\ H_2<T+\Delta h \le H_1, \begin{cases} \varepsilon_1=100\% \\ \varepsilon_2=a(H_2\text{-}\Delta h)-b; \end{cases} \\ T+\Delta h>H_1, \begin{cases} \varepsilon_1=a(H_1\text{-}\Delta h)-b \\ \varepsilon_2=a(H_2\text{-}\Delta h)-b_\circ \end{cases} \end{cases} \tag{8}$$

In the formula, ε_1 is loading rate of ship when water depth is H_1; ε_2 is loading rate of ship when water depth is H_2.

(2) The second situation is $H_2 < \Delta h < H_1$. As shown in Fig 2, there are two types of ships will be affected by this situation.

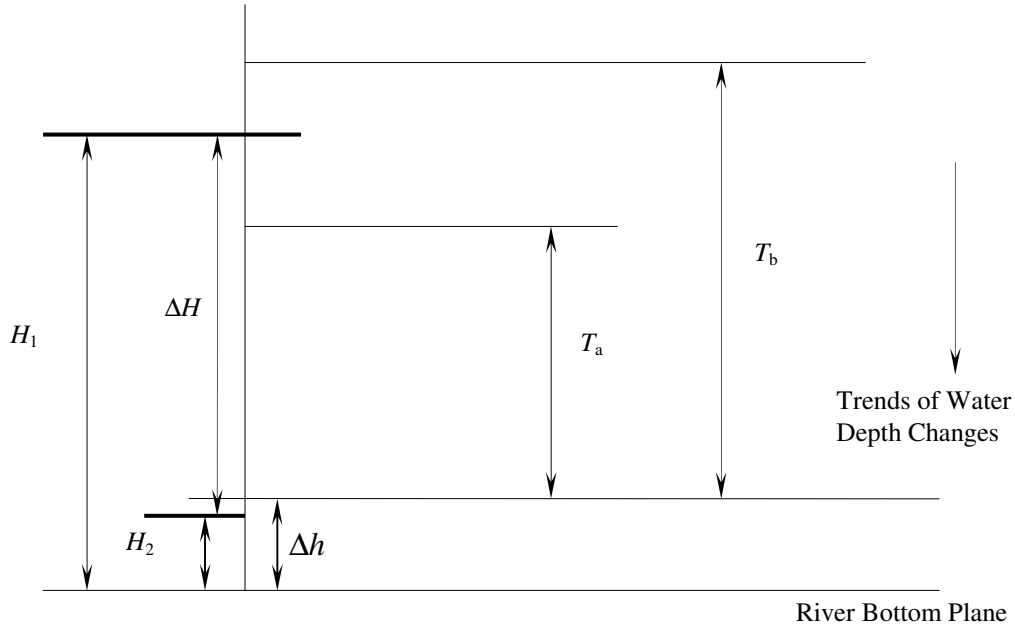

Fig.2 A Conceptual Model between Water Depth and the Draft of all Types of Ships(2)

①Type A. The seaworthy water depth of type A ships is $T_a+\Delta h$ when it is full load, and $H_2<\Delta h \le T_a+\Delta h \le H_1$, it shows that the ships can achieve full load under the first condition of water depth; but under the second condition of water depth, H_2 is less than Δh, ships can't achieved by shedding for ensuring safe navigation, then type A ships ran aground.

②Type B. The seaworthy water depth of type B ships is $T_b+\Delta h$ when it is full load, and $H_2<\Delta h<H_1<T_b+\Delta h$, it shows that the ships can't achieve full load under the first condition of water depth, loading rate is $\varepsilon_{b_1}=a(H_1\text{-}\Delta h)\text{-}b$; but under the second condition of water depth, type B ships ran aground like type A ships.

Obviously, when $H_2<\Delta h$, water depth can't ensure the additional water depth for safe navigation, then all ships are in suspended state. Based on the above analysis, when water level condition is satisfied $H_2<\Delta h<H_1$, loading rate model of ship is expressed as follows:

$$\begin{cases} H_2 < \Delta h < T + \Delta h \le H_1, \begin{cases} \varepsilon_1 = 100\% \\ \varepsilon_2 = 0; \end{cases} \\ H_2 < \Delta h < H_1 < T + \Delta h, \begin{cases} \varepsilon_1 = a(H_1 - \Delta h) - b \\ \varepsilon_2 = 0. \end{cases} \end{cases} \tag{9}$$

（3）The last situation is $H_2<H_1<\Delta h$ .This situation exists in theory, namely before and after changes of water depth all are less than the additional water depth. Ships all are in suspended state, and have no significance, so this article excluded this situation.

Thus, water depth affects choice of ships and loading rate. Generally, the smaller the ship, the smaller impact subject to condition of water depth changes. Water depth changes ultimately affect the cargo capacity, voyage costs and revenues[4]. Broadly, it will affect entire shipping benefits.

Conclusion

This article analyzes the relationship between water level and channel capacity, small ships affected by water level changes is smaller than the large ships, the actual amount of cargo related to design parameters of the ship. And proposed the quantitative model of impact of water level changes on channel capacity. But in the actual voyage, other factors should be considered such as channel width, clearance height, curved radius[1][5]. it has an important significance for shipping cost control, logistics planning and shipping management, business operations and scheduling shipping.

Keywords: reef, sequence stratigraphy, Seismic multiple attributes, neural network, porosity

Abstract: Carbonate reef reservoir buried deeply, show great heterogeneity, Therefore, effective reservoir prediction is the key to the biohermal reservoir. In practical research, based on of the single well sequence stratigraphic framework, combined with these sequence stratigraphic framework and seismic section, found the reservoir development area in the longitudinal, which sq1-HST and sq3-HST is the main period of reservoir development, and then through the seismic Seismic multiple-attribute inversion, predicted porosity of system tracts of reservoir development in the sequence stratigraphic framework. Porosity inversion results shown, Changxing formation reservoir is mainly distributed in the central and north-central of Jiannan area.

Introduction

In recent years, carbonate reef reservoir prediction is the focus of oil and gas exploration. However, reef bank reservoir show great heterogeneity in the lateral, porosity Variation in space, caused a certain extent difficulty in the prediction of reef reservoir. In this reseach, integrated sequence stratigraphy and geophysical inversion method, under the sequence stratigraphic framework, predicted porosity of Changxing formation reservoir, finally find out the spatial distribution characteristics of reservoir.

1 reservoir development section in sequence stratigraphic framework

Platform margin reef mainly developed in Zhuxi area of the northern highlands in 3D study area, moundy reflection in seismic profile, has the typical characteristics of reef reflection. The typical well is well Jianzhu1, which drill Jianzhuxi reef (Figure 1), reef reservoir of well Jianzhu 1 was mainly developed sq1-HST and sq3-HST in the four grade sequences, which is phase 2 and phase 3.

2 the principle of porosity inversion

During this research, we selected method of seismic multi-attribute inversion to predict porosity value. Seismic multi-attribute inversion is process that change seismic internal attributes into lithologic character curve. Seismic internal attributes included instantaneous attributes, time-frequency attributes, filter sections, derivative, integral property attribute, time (linear gradient)and other types. Firstly, we selected seismic attributes that have best fitting advantage degree with the quasi porosity curve, then, used neural network algorithm to establish the nonlinear relationship the various attributes that have selected and quasi porosity curve, applied this relationship to extrapolate seismic attribute, finally, we got the prediction of porosity profile.

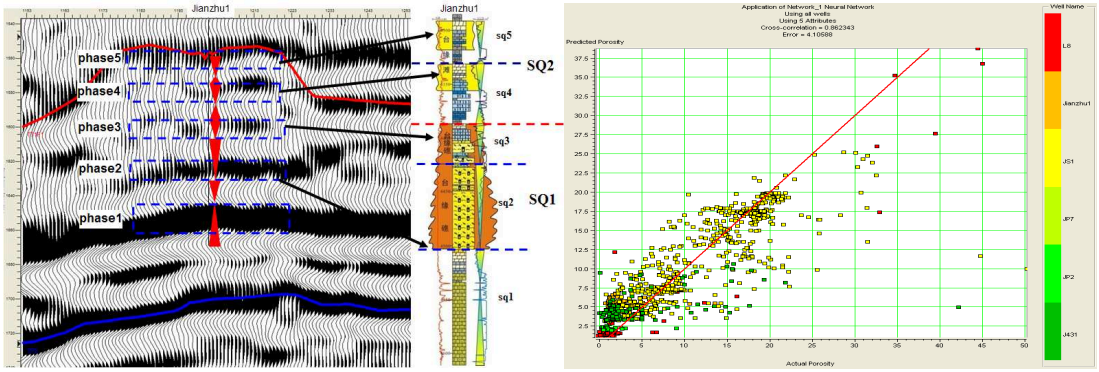

Fig.1 Seismic profile calibration of the 4th sequence in Changxing formation

Fig.2 The relationship between seismic attributes and porosity nonlinear coincidence rate diagram

When we established combination of seismic multi-attribute and quasi porosity curve, used the algorithm of multivariate regression and neural network. Multiple regression algorithm is directly applying the linear weighted, got linear relationship of the predicted characteristic curve and multi-attribute of seismic, but between the seismic attributes combination and the predicted characteristic curve is not simple linear relationship , its exists a complex nonlinear relationship. In the course of practical research, we used of neural network algorithm, through its independent learning established the nonlinear mapping relationship between seismic attributes and quasi porosity curve. Then, used neural network algorithm to fit, that between borehole side seismic attributes and quasi porosity curve correlation degree is 0.86(Fig.2), with such obvious effect, shown that this method is effective.

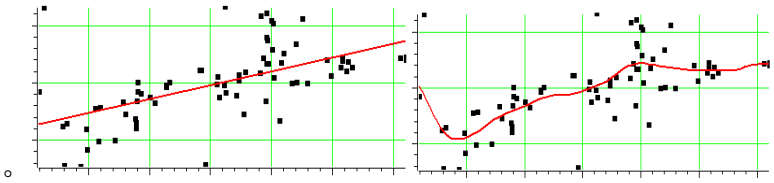

Fig.3 Linear relationship (left) and nonlinear relationship diagram (right)

Neural network probability model is the core algorithm of multi-attribute inversion. To description of the relationship between multiple-attribute is the most suitable statistical relationship, the best method of multi-attribute solving the objective function is neural network, and Kriging method has been widely used and spatial interpolation calculation. In this paper, we combine those algorithm, Which provided the core effective technology for the inversion of physical parameters of high resolution.

Firstly, according to the seismic multi-attribute and the objective function to form amulti-dimensional matrix:

$$\begin{aligned}&\{A_{11}, A_{21}, A_{31}, L_1\}\\&\{A_{12}, A_{22}, A_{32}, L_2\}\\&\cdot\\&\cdot\\&\cdot\\&\{A_{1n}, A_{2n}, A_{3n}, L_n\}\end{aligned} \tag{1}$$

Where, Li is the target curve. Given a set of training data:

$$x=\{A_{1j}, A_{2j}, A_{3j}\} \tag{2}$$

Estimate a new output curve :

$$\hat{L}(x)=\frac{\sum_{i=1}^{n} L_i \exp(-D(x,x_i))}{\sum_{i=1}^{n} \exp(-D(x,x_i))} \tag{3}$$

Where:

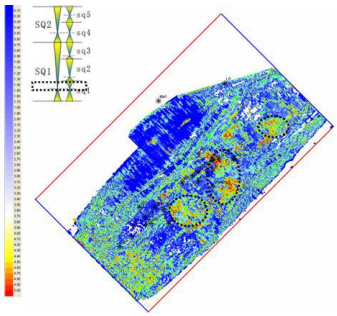
$$D(x,x_i)=\sum_{j=1}^{3}\left(\frac{x_j-x_{ij}}{\sigma_j}\right)^2 \tag{4}$$

Calculate the checksum error:

$$\hat{L}_m(x_m)=\frac{\sum_{i\neq m} L_i \exp(-D(x_m,x_i))}{\sum_{i\neq m}^{n}\exp(-D(x_m,x_i))} \tag{5}$$

3 Porosity prediction in sequence stratigraphic framework

Higher porosity development areas are obviously controlled by the distribution scope of biological reef as shown in Fig 4 prediction map for reservoir porosity of sq1-HST. The higher porosity development areas are mainly central Jianzhuxi reef and south-central Jinzhuping reef. Northern small-scale area partly high position expose action may be caused by regression, the formative exposed bank body developed high porosity reservoir, the small-scale high position of Well 47 in the southwest is the high porosity reservoir development area.



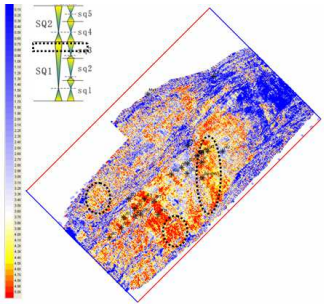


Fig.4 Sq1-HST Reservoir porosity prediction in Jiannan 3D work field

Fig.5 Sq3-HST Reservoir porosity prediction in Jiannan 3D work field

As shown in Fig 5, prediction map for reservoir porosity of sq3-HST.sq3-HST is the main development of reef and exposure. Central and southern reef bank exposed and formed high porosity reservoir, in the south is main distributed bioclastic beach, in the north, Linxichang area, small-scale area developed high porosity reservoir.

Conclusion

This paper is based on the single well sequence stratigraphy, well log and seismic data, to establish the sequence stratigraphic framework. In sequence stratigraphic framework, calibrated the reservoir, summarizes the seismic response characteristics of reservoir, clear the reservoir vertical development area. Using Seismic multi-attribute inversion，building nonlinear relationship between porosity curve and seismic gather，and forecasting of reservoir porosity respectively in sq1-HST and sq3-HST period, this method can be more reliable for the prediction of reef reservoir.

cuitao1203@163.com

Keywords: WZD area; Bauxite; acidity and alkalinity

Abstract: Acidity and alkalinity of metallogenetic environment in penecontemporaneous period is very important for the informing of high grade bauxite. Through the research on migration regular of elements, the position of rare earth mineral and the qualitative alternation of bauxite we found that metallogenetic environment is acidic in penecontemporaneous period, from top to bottom of the profile acidity is decreased gradually. In the acidic condition, Si and Fe moved downward but Al is relative enrichment in the middle-upper part of profile.

Introduction

There is abundant bauxite in WZD area. For a long time many experts and scholars have research on the bauxite of rocks and minerals, chemistry, sedimentary environment, provenance, mineralization age [1-6]. Former researcher have a great outcome on bauxite, But the research on acidity and alkalinity of metallogenetic environment in penecontemporaneous period is poor, this paper have a research on acidity and alkalinity by analysis on migration regular of elements, the position of rare earth mineral and the qualitative alternation of bauxite.

Geological setting

WZD bauxite is located in Wuchuan, Zheng'an and Daozhen County, northern Guizhou, which is an important part of centre Guizhou-southern Chongqing bauxite belt [7]. The regional tectonics position of the study area is in the fold belt in northern Guizhou of the upper Yangtze Block[8]. The main strata in WZD area from the oldest to the youngest including: Cambrian, Ordovician, Silurian, Permian, Triassic and Jurassic. Cambrian is mainly distributed in the core of anticlines, Triassic and Jurassic are mainly distributed in the core of synclines. Bauxite is underlying the LiangShan formation(P2l) or Qixia formation(P2q) of the middle Permian, overlying the HuangLong formation(C2h) of upper Carboniferous or the Hanjiadian formation of the lower Silurian(S1hj).The bauxite is stratiform and unconformable with the underlying and overlying strata. Fig.1 shows that the distribution of the bauxite was controlled by nine synclines. The thickness of the bauxite is 0.68-15.7m, the profile can be divided into two lithology parts: the upper part is aluminous rock, dominated by high grade bauxite or half grade bauxite; the lower part is low grade bauxite. According to the lithological and textural properties, the natural types of bauxite deposit can roughly be subdivided into four categories: massive bauxite, oolithic bauxite, clastic bauxite and earthy bauxite.

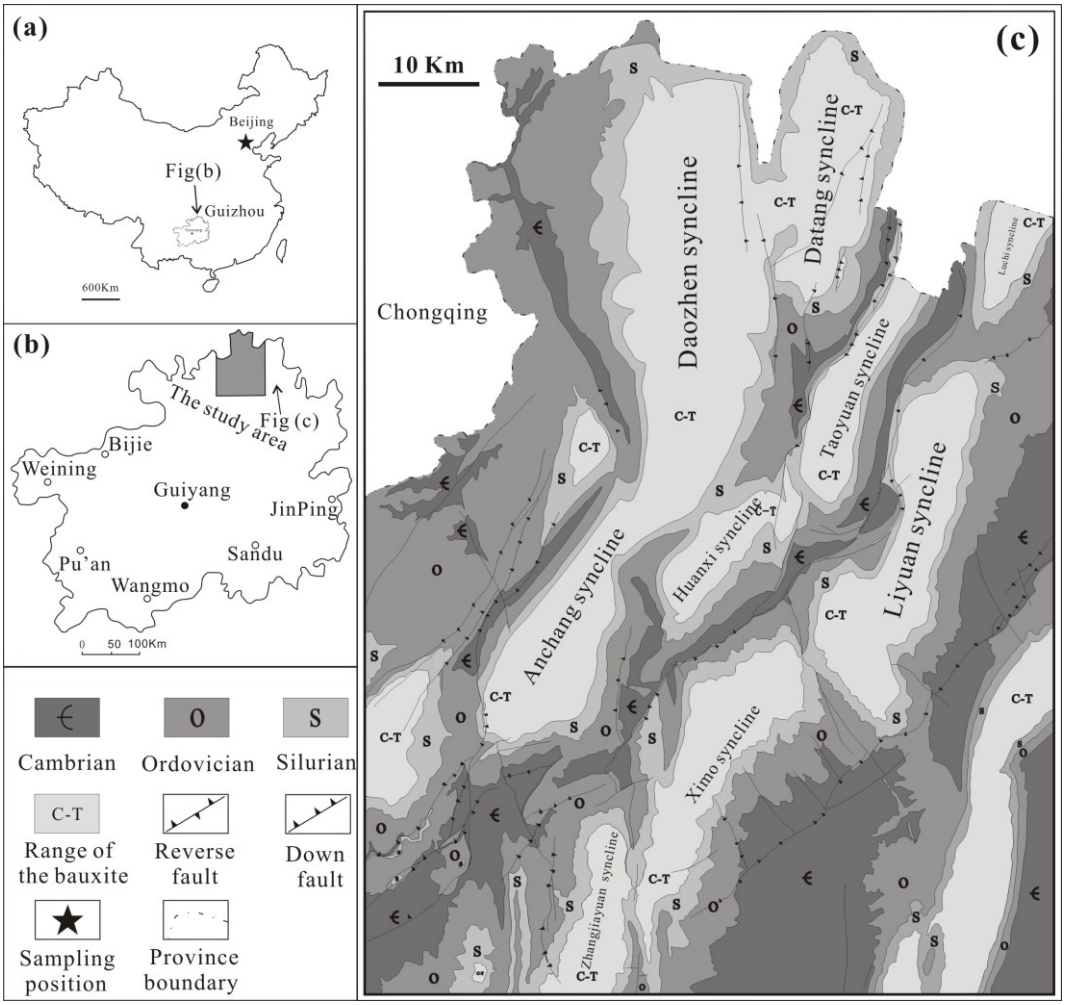

Fig. 1(a)Locality map of Guizhou,(b)The map showing the location of the study area, (c)Geology map of the WZD area in northern Guizhou

Acidity and alkalinity of metallogenetic environment in penecontemporaneous period

Major elements of the WZD bauxite are Al_2O_3, SiO_2, Fe_2O_3 and TiO_2 [6,8], ranges of these elements are wide and have a great change in numerical value[8]. Elements of alkaline metal have a great loss show that it is obvious acidic in the metallogenetic process[8]. wide range of alkaline indicates different position of the producing formation has different acidity and alkalinity, and biomarker in the WZD bauxite indicates acidic environment too[9]. Fig.2 shows that Al_2O_3 has negative correlations with SiO_2 and Fe_2O_3, forming process of high grade bauxite is a process that Si and Fe have a great loss but Al have a relative enrichment. In the acidic environment Si and Fe elements are active and migrate accompany movement of groundwater. This process is beneficial for the forming of high grade bauxite. Ti is very stable and just move in very strong acidic environment, Ti has a positive correlation with Al, and it shows that Ti has a movability in the WZD bauxite. The movability of Ti has demonstrated metallogenetic environment is strong acidic.

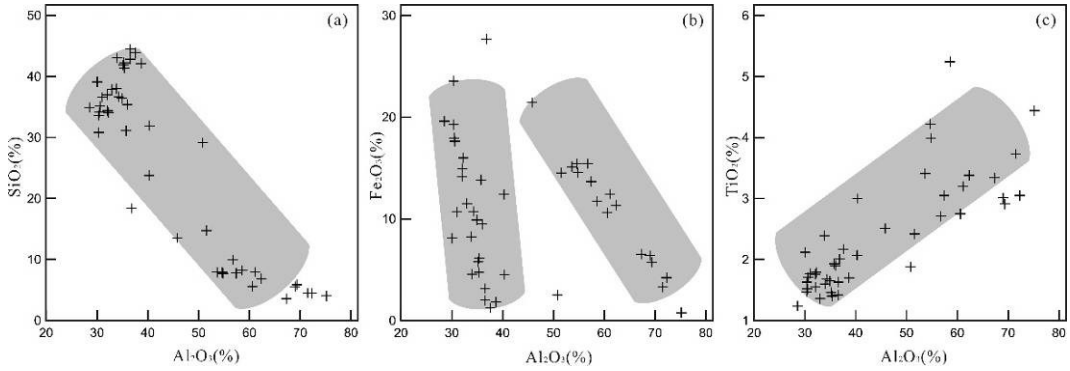

Fig.2 a. Correlation between Al_2O_3 and SiO_2; b. Correlation between Al_2O_3 and Fe_2O_3; c. Correlation between Al_2O_3 and TiO_2[8]

Pyrite is an important of the bauxite, and organic material too. The forming process of Pyrite and the decomposition of organic material would cause the forming of sulphuric acid and organic acid. The metallogenetic environment is strong acidic because of sulphuric acid and organic acid. Two kinds of acid have a downward moving trend Sulphuric acid and organic acid have been gradually neutralized as the downward movement. Si and Fe would be dissolved and moved to the bottom of the profile. In the moving process, Sulphuric acid and organic acid have decreased gradually, so the Si and Fe elements would precipitated in the lower part of the producing formation. Rubble of karst is frequent in the surface of Huanglong formation. Fig.3 shows that there is hollow between limestone of Huanglong formation and bauxite. Rubble of karst and hollow have demonstrated that karstification is an everlasting process after the sediment deposit, limestone of Huanglong formation would be dissolved by the Sulphuric acid and organic acid from top.

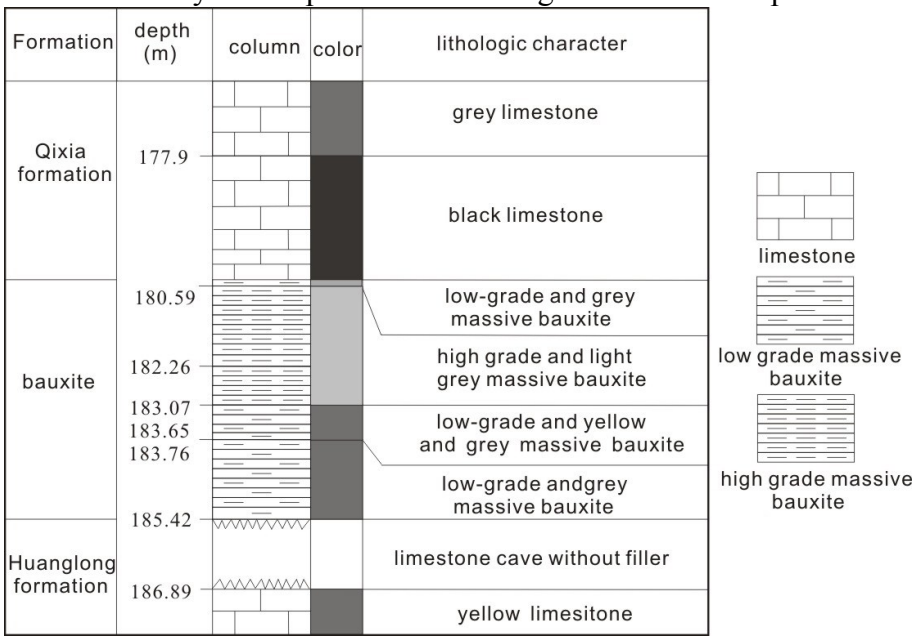

Fig.3 Bore section 1603

Acidity of environment decreased gradually from top to bottom, at last it may be alter to alkalescence environment, and the appearance of Metaparisite($Ce_2Ca(CO_3)_3F_2$) which is just appears in the alkalescence environment prove it [6,8]. $Ce_2Ca(CO_3)_3F_2$ has been discoveryed in Liyuan syncline, Ximo syncline. The appearance of $Ce_2Ca(CO_3)_3F_2$ causes severe positive anomaly of Ce, in other words alkalescence environment resulting in the severe positive anomaly of Ce.

Conclusion

The main conclusions from this study are summarized as follows: 1)metallogenetic environment in penecontemporaneous period of WZD bauxite is acidic, and from top to bottom of profile, acdiity of environment decreased gradually.2)In the acidic metallogenetic environment Si and Fe have a great loss but Al has a small loss resulting in the formation of high grade bauxite in the upper and middle part of the producing formation.

Keywords: computer vision, fundamental matrix, epipolar geometry, non-linear optimization

Abstract. The accurate estimation of the fundamental matrix is one of the most important steps in many computer vision applications such as 3D reconstruction, camera self-calibration, motion estimation and stereo matching. In this paper, an optimal fundamental matrix estimation method based on removing exceptional match points is proposed. Firstly, the initial mismatch is reduced by the bidirectional SIFT feature matching algorithm. Secondly, the partial concentration problem of random samples is solved by the bucket segmentation method. In order to obtain robustness, the fundamental matrix is estimated in a RANSAC framework according to the principle of minimizing the geometric distance. Finally, the iterate process improves the accuracy of the fundamental matrix by using the LM algorithm. Experimental results show that the proposed method can reduce the outlier's interference better and improve the estimation precision of the fundamental matrix.

Introduction

The fundamental matrix contains the epipolar constraint information that existing between two images about the same scene. It only relates with the interior parameter of the camera and the relative posture of two camera positions. It is independent of the scene structure [1]. The accurate estimation of the fundamental matrix is one of the most important steps in many computer vision applications such as 3D reconstruction, camera self-calibration, stereo matching and motion estimation, and so on. Therefore, how to estimate the fundamental matrix as accurately as possible is still an important issue in computer vision research.

The mismatched feature pairs and the features with large location error all belong to the outliers. The noise and outliers unavoidably exist in the initial matching feature pairs. They will lead to low precision or wrong result. Methods for estimating the fundamental matrix can be divided into three categories: linear method, iterative method and robust method [2]. The seven point algorithm, the eight point algorithm and the improved eight point algorithm [3] are linear methods. Because the seven point algorithm and the eight point algorithm are more sensitive to data noise, Hartley proposed the improved eight point algorithm which can reduce the noise interference by normalizing the initial feature pair data. The iterative method solves the minimization problem of the Euclidean distance sum between feature points and their corresponding epipolar lines. Usually the Newton-Raphson or Levenberg-Marquardt algorithm is applied in solving the iterative optimal problem. Although the estimation result of the iterative method is more accurate than that of the linear method, but it is more time-consuming and can't deal with the outliers. The robust estimation algorithm can reduce the interference caused by the outliers. The M-estimators, LMeds and RANSAC are robust methods.

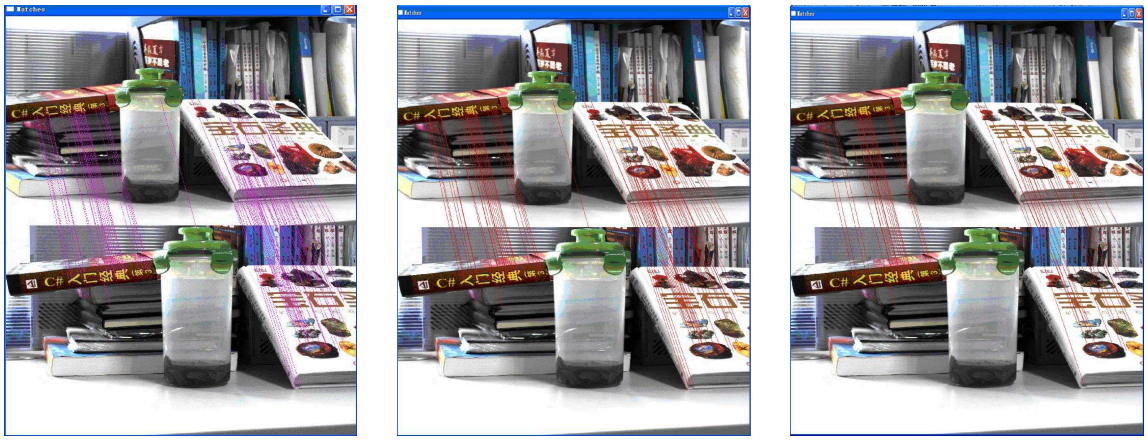
In this paper, an optimal algorithm for estimating fundamental matrix is proposed based on removing the outliers. First, some mismatched features are reduced by the bidirectional SIFT feature matching algorithm. Then, the partial concentration problem of random samples is solved by bucket segmentation method. In order to remove the outliers, the fundamental matrix is estimated in a RANSAC framework. Final, the iterate process leads the estimation to a more accurate level by using

the Levenberg-Marquardt algorithm. The experimental results of real image examples show the effectiveness of the proposed method.

Bidirectional SIFT Feature Matching Algorithm

The steps of bidirectional SIFT feature matching are shown as follows. Firstly, the SIFT features of the two images are extracted by the SIFT feature detection method. Secondly, the SIFT feature matching pairs are calculated from the left image to the right image by the K-nearest neighbor matching method. Finally, the matching pairs from the right image to the left image are calculated from the matching pair sets obtained in the previous step by using the K-nearest neighbor matching method again. Matching threshold in both directions can be different.

The results of bidirectional SIFT feature matching are shown in the Fig.1. The SIFT feature number of the left image (on the top) is 3422 and that of the right image (on the bottom) is 3235. When the matching threshold T1 (from left image to right image) is 0.06, the number of matched pairs is 94. The results of the unidirectional SIFT feature matching are shown in Fig.1(a). When the matching threshold T1 is 0.06 and the matching threshold T2 (from right image to left image) is 0.06, the number of matched pairs is 91. The results of bidirectional SIFT feature matching are shown in Fig.1(b). When T1 is 0.06 and T2 is 0.03, the number of matched pairs is 55. The results of bidirectional SIFT feature matching are shown in Fig.1(c). The matching threshold is smaller, the mismatch suppression is stronger, and the number of final matching pairs reduces faster. The bidirectional SIFT feature matching algorithm can be used to provide more accurate matching pairs.



(a) T1=0.06; (b) T1=0.06, T2=0.06; (c) T1=0.06, T2=0.03

Fig. 1. The match results calculated by the bidirectional SIFT feature matching algorithm

Fundamental Matrix Estimation Based on Removing Outliers

The bidirectional SIFT feature matching algorithm provides an initial matching pair list for estimating the fundamental matrix. Note that the initial matching pair list still contains some outliers caused by large feature location error. In order to reduce their negative effect on estimating fundamental matrix, we proposed a new method for estimating fundamental matrix robustly by removing the outliers. Firstly, a more accurate initial fundamental matrix F is estimated from a number of random samples. Every random sample consists of the minimal sets selected from the matching pair list. Secondly, the Euclidean distance of each matching pair is calculated by the F. The outliers can be removed by comparing their Euclidean distances with the distance assessment threshold. The inliers list is obtained by removing those outliers from the initial matching pair list. Finally, the accurate fundamental matrix is estimated optimally from the inliers list by a classical iterative Levenberg-Marquardt algorithm.

Bucket Segmentation. In robust estimation algorithm, the sample is selected randomly from the matching pair list. If the samples concentrate locally, they can’t reflect accurately the epipolar

constraint relations of the whole image. The fundamental matrix estimated by these samples is not accurate. The bucket segmentation is applied to solve the partial concentration problem of the samples.

The image plane is divided into several buckets averagely. The bucket segmentation result is shown in Fig.2. The hit probability of each bucket is determined by the number of the feature points located in this bucket. In eight point algorithm, eight matching pairs are applied to calculate fundamental matrix. The eight matching pairs are selected randomly as follows. First, eight non-empty buckets are selected randomly according to their hit probability. Then, one feature point is selected randomly from one non-empty bucket. The samples consisting of such selected feature points can avoid partial concentration problem [4]. The fundamental matrix estimation is more stable and accurate when use such samples.

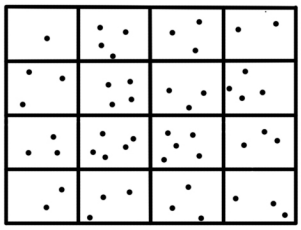


Fig. 2. Dividing the image plane into 4×4 buckets

Refinement in the RANSAC Framework. The outliers will affect the estimation accuracy of the fundamental matrix when nonlinear optimization algorithm is performed directly over the matching pair list with outliers. Therefore, the fundamental matrix is estimated in RANSAC framework [5] and is refined by the LM iterative algorithm. The algorithm process is as follows.

Step 1: The initial matching pair list is obtained by the bidirectional SIFT feature matching algorithm. It is labeled as {mi, mi'}, i=1, ... , N.

Step 2: The image plane is divided into S(S>=8) buckets averagely. The number of matching feature points of each bucket is calculated. It is labeled as Ns, s=1,...,S. The hit probability of each bucket is Ps, Ps=Ns/N.

Step 3: The RANSAC times K in the algorithm is determined by:

$$K = \frac{\log(1-P)}{\log(1-(1-\varepsilon)^{v})} \tag{1}$$

Where P represents the confidence probability that the estimated fundamental matrix is correct, ε is the fraction of outliers, v is the sample size. (v is 8 when the improved eight point algorithm is used to calculate the fundamental matrix).

Step 4: Repeat K times random sample.

(1) According to each bucket's hit probability Ps, eight matching pairs are selected randomly from the initial matching pair list by the bucket segmentation method;

(2) The fundamental matrix F_j is estimated by improved eight point algorithm with this sample;

(3) The Euclidean distance r_i of each match pair can be calculated with the F_j;

$$r_i = (d^2(m_i^{'}, F_j m_i) + d^2(m_i, F_j^T m_i^{'})) = (\frac{1}{(F_j m_i)_1^2 + (F_j m_i)_2^2} + \frac{1}{(F_j^T m_i^{'})_1^2 + (F_j^T m_i^{'})_2^2})(m_i^{'T} F m_i)^2 \tag{2}$$

Where d2(*,*) represents the Euclidean distance between a feature point and its corresponding epipolar line.

(4) The element of set { r_i } is arranged in ascending order. The error evaluation index e_j of F_j is the sum of the element r_i located in front of (1-ε)×N.

Step 5: The set of $\{F_j \rightarrow e_j\}$, j=1, … , K can be obtained from the step 4. Find the minimal error $e_{\min} = \min_j \{e_j\}$ and its corresponding fundamental matrix F_{min} from the set. This F_{min} is picked out as the winner and is relabeled as F_{opt}. The new set $\{r_i^{'}\}$ is obtained by recalculating the Euclidean distance of each matching pair with the F_{opt}. After arranging the element of set $\{r_i^{'}\}$ in ascending order, the error evaluation index r_{min} of F_{opt} is calculated in the same way. Then the distance assessment threshold T is determined by:

$$T = 2.5 \times \frac{1}{\phi^{-1}\left(0.5 + \left(\frac{1-\varepsilon}{2}\right)\right)} \times \left(1 + \frac{5}{N-v}\right) \times \sqrt{r_{\min}} \tag{3}$$

Where ϕ is the cumulative standard normal distribution function, ϕ^{-1} is its inverse function [6].

If the Euclidean distance of one matching pair $r_i^{'}$ is greater than the distance assessment threshold T, this matching pair is the outlier and should be removed. Then, the final inliers list is obtained by removing those outliers from the initial matching pair list.

Step 6: The final fundamental matrix F is estimated optimally with a classical LM iterative algorithm using the final inliers list. The error cost function is determined by:

$$\sum_i^N (d^2(m_i^{'}, Fm_i) + d^2(m_i, F^T m_i^{'})) \tag{4}$$

Experimental Results

First, the fundamental matrixes of some real image pairs are estimated by the proposed algorithm. The epipolar constraint can be calculated from the fundamental matrix. Fig.3 shows the recovered epipolar lines and the correspondence matching points of the corridor image. Fig.4 shows the recovered epipolar lines and the correspondence matching points of the sculpture image. In order to keep image content clear to the reader, only ten recovered epipolar lines are superimposed on the image. Then, the accuracy of the fundamental matrix estimated by the proposed algorithm is compared with that estimated by the improved eight point algorithm, LMeds and RANSAC. The experiment parameters are listed as follows. In the proposed algorithm, P is 99%, ε is 0.35, v is 8, bucket size is 5×5. The improved eight point algorithm, LMeds and RANSAC methods are achieved by the OpenCV function library. In the LMeds and RANSAC functions, the distance assessment threshold T that represents the maximum distance from point to epipolar line in pixels is one pixel. The confidence probability is 99%. The effectiveness criterion is fundamental matrix's quality to satisfy the epipolar constraint, and that is the mean value of the Euclidean distance sum (MVEDS) of all matching pairs. The MVEDS and the inliers number are listed in table 1. The initial matching pairs are calculated by the bidirectional SIFT feature matching algorithm. The number of initial matching pairs in Fig.3 is 170. The number of initial matching pairs in Fig.4 is 393.

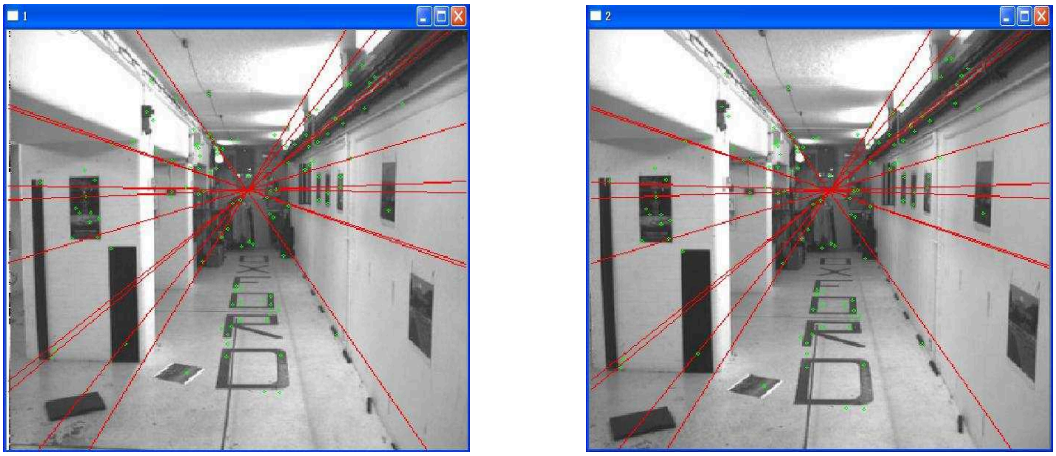

Fig. 3. Corridor images with epipolar lines (red lines) and 136 matching pairs (green points) superimposed

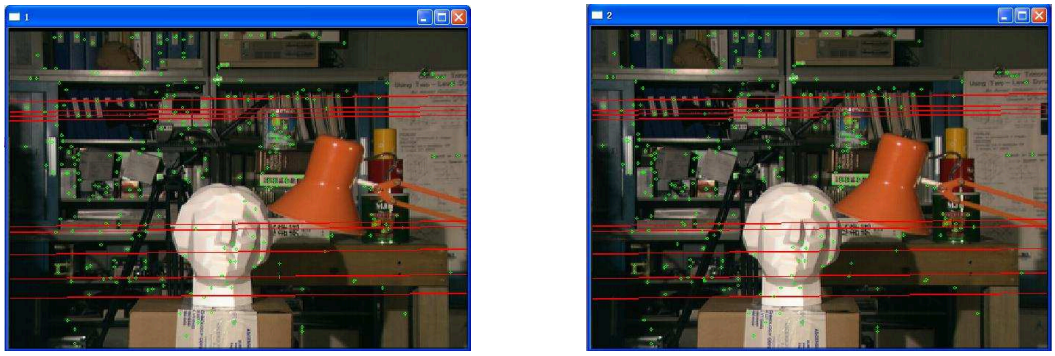

Fig. 4. Sculpture images with epipolar lines (red lines) and 348 matching pairs (green points) superimposed

Table 1. The accuracy comparison of four estimation algorithms

Image pair	appraise criteria	improved eight point algorithm	LMeds	RANSAC	proposed algorithm
Fig. 3	MVEDS [pixels]	0.329257	0.164709	0.263084	0.119275
Fig. 3	inliers number	170	151	147	136
Fig. 4	MVEDS [pixels]	0.390452	0.019153	0.092462	0.018656
Fig. 4	inliers number	393	342	381	348

The MVEDS calculated by the improved eight point algorithm is maximal in four algorithms because it can't deal with the outliers. Due to removing some outliers, the fundamental matrixes estimated by LMeds and RANSAC are more accurate than that estimated by the improved eight point algorithm. The proposed algorithm can remove the outliers and apply the nonlinear optimal iterate process to estimate fundamental matrix. Its accuracy is the highest in four algorithms.

Summary

The outliers existed in the initial matching pairs will affect the accuracy of fundamental matrix. The proposed algorithm can improve the accuracy of the fundamental matrix estimation by removing the outliers. The initial mismatch is reduced by the bidirectional SIFT feature matching algorithm. The fundamental matrix is estimated in a RANSAC framework and is refined by the LM iterative algorithm. The experimental results show that the proposed algorithm provides a more accurate solution of the fundamental matrix than the traditional linear method and robust methods.

Keywords: Complex networks; High degree seeking; Search steps; Query information.

Abstract. Application value of a variety of complex network makes it become an important scientific research challenges. Therefore, in order to more thoroughly understand the network of human life, we need to further study the properties of the complex network. Complex network search theory solves many practical problems, including the search of relationship between any two people in a social network chain.

The complex network and personalized recommendation system introduction

1.1 Main topology characteristic of complex networks

Aggregation coefficient

Aggregation coefficient C is used to identify the node in the system of collection, namely how dense network is. Its calculation is: if the node i connect k_i side and the other k_i node is linked together, assuming node to connect each other, between them, a total of $k_i(k_i-1)/2$ side, between the node k_i actually there is E_i sides; the ratio of both side is gathered coefficient of the node i:

$$C(i)=\frac{2E_i}{k_i(k_i-1)} \qquad (1)$$

Aggregation coefficient of the system is the mean of all the nodes in the network:

$$C\frac{1}{N}\sum_{i=1}^{N}C(i) \qquad (2)$$

The average shortest path

There is one or more connection route between any two nodes in a network, the shortest path is one of the least connection node numbers, and the average shortest path of the network is the average of all the shortest path length.

Assume the connected graph $G(V,E)$ is a group for the node set V, take $E\subseteq\{(v_i,v_j):v_i,v_j\in V\}$ as the edge collection; $l(v_i,v_j)$ is the shortest path between any two nodes v_i and v_j, then the average shortest path L of graph $G(V,E)$ is:

$$L=\sum_{(v_i,v_j)\in V}l(v_{i,}v_j) \qquad (3)$$

1.2 The business process of personalized recommendation system

From information acquisition to the recommendation of all process personalized recommendation system include the following processes: processing the data; model; recommendations; data update; the user feedback.

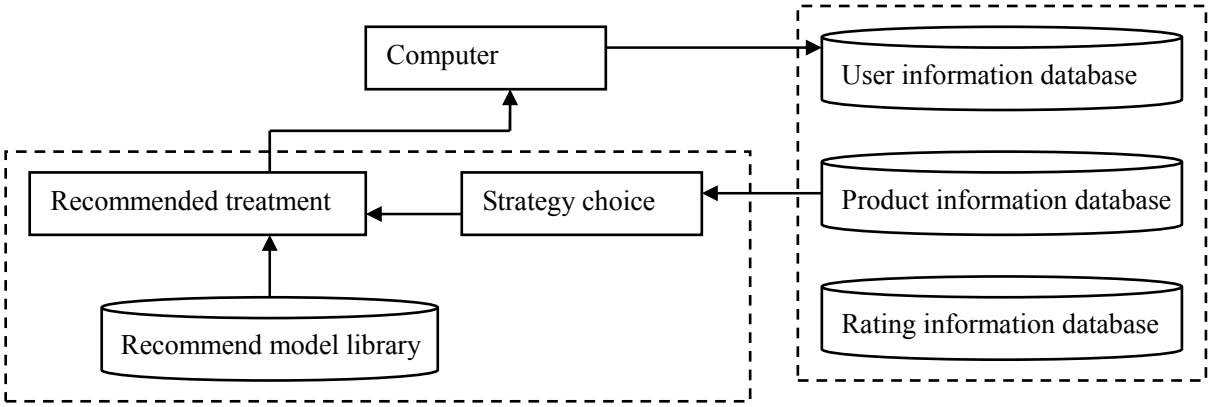

Figure1. Recommendation system overall framework

Information recommendation algorithm based on network structure

So far, the research and application of the collaborative filtering is considered to be one of the most widely algorithm, this algorithm is a basic assumption in the past with similar preferences of the user in the future will have similar preferences. [1]Therefore, the collaborative filtering algorithm is one of the most important thing is how to measure the similarity between the users.

2.1 Collaborative filtering recommendation algorithm

A scoring system can be displayed by the second part network $G(U,O,E)$; U, O, E represent the users, commodities and the edge (marked as score values). Assume $r_{u\alpha}$ for score value of users u to the goods α, O_u said goods collection of user u. U_α is a collection of all users. Score of u is $\overline{r_u} = 1/|O_u| \sum_{\alpha \in O} r_{u\alpha}$. [2]Using collaborative filtering algorithm, predictive value for user u and goods is:

$$r'_{n\alpha} = \overline{r_n} + k \sum_{v \in U_\alpha} s_{nv} (r_{v\alpha} - \overline{r_v}) \quad (4)$$

s_{uv} is the degree of similarity showed by u and v, $k = (\sum_v s_{nv})^{-1}$ is the normalized coefficient. A similarity calculation index which use score information is the Pearson coefficient,

$$s_{nv} = \frac{\sum_\alpha (r_{n\alpha} - \overline{r_n})(r_{v\alpha} - \overline{r_v})}{\sqrt{\sum_\alpha (r_{u\alpha} - \overline{r_v})^2} \sqrt{\sum_\alpha (r_{v\alpha} - \overline{r_v})^2}} \quad , \quad \alpha \in O_u \bigcap O_v \quad (5)$$

2.2 Information recommendation algorithm based on network structure

The algorithm of this chapter can be divided into two steps: first, we put the two parts of users - goods projection to the single mode network, when include two users have at least one common grading goods, we connect between the two users by an edge; secondly, based on the single mode of network, we can make use of random walk with restart algorithm to calculate the similarity between users. Suppose that a random walk starting from node i, go to the next node at c probability and the probability of $1-c$ to return to the initial node. [3]Assuming s_{ij} as probability of random walk in a stable state j, then

$$\vec{s_i} = cP^T \vec{s_i} + (1-c)\vec{e_i} \quad (6)$$

Random walk with restart process is similar to Google's PageRank, in fact, the PageRank algorithm learns from the random walk with restart process. Suppose g_i as the probability on the on stop page then the PageRank algorithm of iterative formula is:

$$g_i = c \sum ij \frac{g_i}{k_j} + (1-c) \quad (7)$$

Average in different network analysis

This part we will discuss the algorithm complexity of the several common complex network.

3.1 Rule network

The rules of the common network mainly include the nearest neighbor coupled network, the global coupling network, star network, etc. In all kinds of network whose node number is the same, global coupling network has minimum average path length of $L_{gc}=1$, the clustering coefficient of maximum $C_{gc}=1$. But as the actual network model the model has a lot of problems.

We take another rule - star coupled network as a model to discuss the algorithm complexity. Star coupled network average path length is:

$$L_{star}=2-\frac{2(|V|-1)}{|V|(|V|-1)}\to 2(|V|\to\infty) \qquad (8)$$

Therefore, average cost k steps wander's most generous algorithm is:

$$T(|V|)_{khds}=2\in 0(1) \qquad (9)$$

The star coupled in the network, the most generous algorithm complexity steps k wander is a constant order $O(I)$. For the new type k traversal search algorithm, take the average path length in:

$$T(|V|)_{k}=2|V|+4\in o(|V|) \qquad (10)$$

3.2 Random network

Different from the rule network, the most important nature of random graph ER is the emergent properties or degeneration, that is given a fixed probability p, we will find that many of its important properties are suddenly sprang up and out, for example, connectivity, all figure almost don't have this nature.

Set path length of random network random graph ER is the average degree of $<k>=p(|V|-1)$, intuitively, to any one of the nodes in the graph, there is one other node in the network and the distance between the point at which is close to or equal to L_{ER}, as a result, $|V|\alpha<k<L_{ER}$, the average path length of random networks are:

$$L_{ER}\propto\frac{tn|V|}{tn<k>} \qquad (11)$$

We can see that the random network has a small clustering coefficient and average shortest path length. Bring the above two formulas in, average cost k steps wander the most generous algorithm is:

$$T(|V|)_{khds}=\frac{\ln|V|}{\ln<k>}+\left\lfloor\frac{\ln|V|}{3\ln<k>}\right\rfloor(|V|-1)\in o(|V|\ln|V|) \qquad (12)$$

The random network, the most generous algorithm complexity of k steps wander is $o(|V|\ln|V|)$. For the new type k traversal search algorithm, take the average path length in, we can get:

$$T(|V|)_{k}=\frac{3|V|\ln|V|}{\ln<k>}-4|V|+4\in o(|V|\ln|V|) \qquad (13)$$

Summary

With the rapid development of computer and Internet technology, network information can be obtained is in exponential growth. But it also leads to information overload, namely, information utilization become lower instead. Recommendation technology is considered to be one of the most effective tools for information overload. Information recommendation technology is a hot issue in scientific research and engineering application..

Algorithm Study and Application of Personalized Intelligent Recommendation Engine

PU Guo-lin[1, a]

[1]School of Computer Science, Sichuan University of Arts and Science, Dazhou 635000,China

[a]PUGuolin@yeah.net

Keywords: Recommendation engines; Personalization; Collaborative filtering

Abstract. The Internet has gradually enters the life of people and the usage of information has become globalization gradually. It is now very common to get information through the network in day-to-day work. The Amount of data of Internet information grows in an explosive way in recent years, the huge amounts of information make it more and more difficult for users to find the information they need accurately; information overload lots problems become the great challenge of Internet development. As currently one of the most effective tool to solve the information overload, personalized recommendation technology help users filter information intelligently through the recommendation engine.

Intelligent recommendation system examples

Intelligent recommendation system is the research focus in the information retrieval and information filtering; now many universities and institutions take it in the key study, classic recommendation system prototype include:

(1) TYPESTRY: TYPESTRY is a research collaborative filtering system; it usually helps users to filter email and news. TYPESTRY system provides a variety of services; mainly a collaborative filtering service, accessorily electronic document storage and user evaluation storage and other services. TYPESTRY also design their independent TQL query. TQL is similar to SQL, it can research for relevant information query according to user's interest preference, and query efficiency is higher. TYPESTRY is mainly based on collaborative filtering technology, so can't satisfy the requirement of real-time for large users of the system.

(2) ACF: Active Collaborative Filtering system is put forward by Cameron University and independently researched and developed, it is the recommendation system based on Collaborative Filtering technology. [1]An important idea of ACF is a pointer, the pointer plays an important role in the collaborative filtering algorithm, a pointer can point to the electronic document hyperlinks, also can point to the electronic document context information or user comments. Through the way of the pointer, synergy will recommend information to the interested users pointer points to.

(3) GroupLens: MIT is the research institution of GroupLens, it is a collaborative filtering technology news information recommendation system. Rating information collected through user to obtain accurate information and build user rating matrix of the project to find the user's neighbor users and then according to the most similar users score calculated recommendation information. The system can meet the needs of large users. GroupLens provide open source data sets, has very high openness, provides a convenient for recommending system research for all structure, users can send the score information through the GroupLens API. We can see form Figure1.

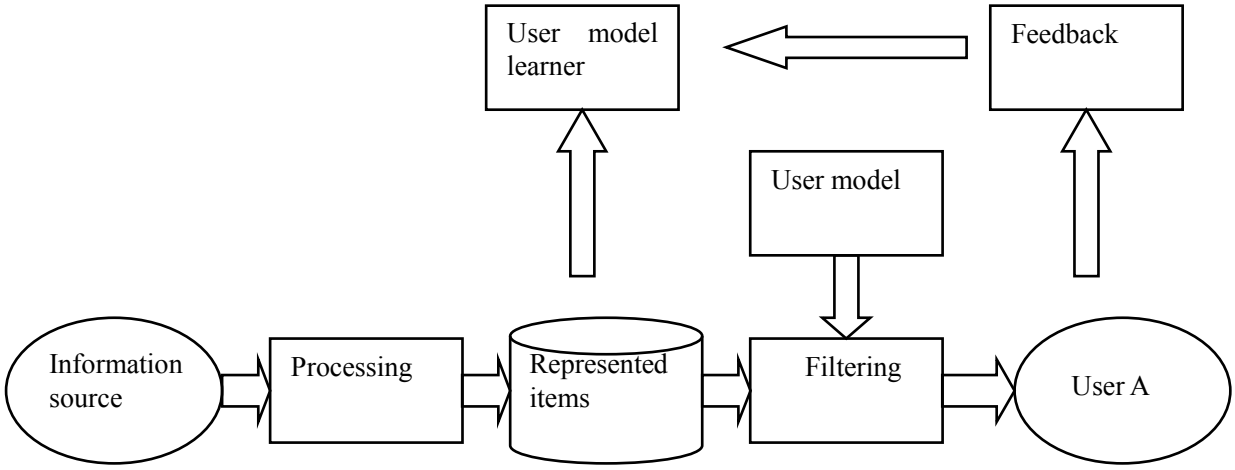

Figure1. Overall architecture of personalized recommendation system design

TF - IDF learning method

The basic idea of TF - IDF method is to take each user/document as a vector, each dimension of the vector is made up of key items, and each feature weight shall be carried out in accordance with the document frequency and word frequency calculation, the whole process need to complete the following two steps:

(1) According to the training sample extract feature item set of text $T = \{t_1, t_2, ...t_n\}$

(2) Measure the size of the feature weight w_{kj} (weight of t_k in d_j);

2.1 Feature extraction

There are two kinds of feature extraction method. One category is Term Selection, referring to selecting a small amount typical and characteristic feature from the original features (a mixture of useful and useless words). [2]However, characteristics of the type don't change, just less. Another kind is called Term Extraction method. Different from Term Extraction, it is to reconstruct the new characteristics out of the original feature set, these new key words more representative, and costs less computation resource. This paper studies feature selection algorithm only.

Feature selection algorithms usually have Document Frequency (DF), Chi-square, CHI test and Information Gain method (IG) and Mutual Information method (Ml) and Document Frequency, etc. This section mainly elaborates the document frequency method, information gain method and CHI method.

(1) Document frequency method

Document frequency (DF) method refers to frequency of a certain term t in corpus document. The specific method is: to calculate document frequency of each term in the training corpus, and then set a threshold value, when document frequency of a term is below a certain threshold to remove it from the feature space, saying the word frequency is too low, not representative; when the document frequency of a term is above a certain threshold, also remove it out of the feature space, saying the term frequency is too high, of no differentiation.

(2) Information gain method

Information gain (IG) method is similar to the attributes choice method, which measures the importance of the term based on the information each term t provides for the entire classification so as to decide trade-offs of term t. information gain for a term of t is the difference between the amount of information for the entire classification caused by a term t that relative to no t. [3]Relevant information gain measurement in text categorization is the difference in the amount of information provided when there is the existence of a certain word for classification, among them, entropy is adopted to measure the size of the amount of information.

$$Gain(t) = Entropy(S) - Entropy(S_t) = \{-\sum_{j=1}^{n} P(C_j) \times \log P(C_j)\}$$
$$- P(t) \times \{-\sum_{j=1}^{n} P(C_j \mid t) \times \log P(C_j \mid t)\} - P(\bar{t}) \times \{-\sum_{j=1}^{n} P(C_j \mid \bar{t}) \times \log P(C_j \mid \bar{t})\} \quad (1)$$

(3) CHI

The basic thought CHI is to determine whether the assumed theory is correct by observing the deviation between the theoretical value and practical value. Generally speaking, the first original are assumed between the two variables are independent, then observe the deviation between the size of the actual value with the theoretical value (in the case of both independent of each other's value) to determine whether to accept the null hypothesis, if the deviation is small enough then accept the null hypothesis; Otherwise deny original hypothesis, accept the alternative hypothesis.

Measure of the theoretical value and practical value deviation is:

$$D = \sum_{i=1}^{n} \frac{(x_i - E)^2}{E} \quad (2)$$

2.2 Feature weight calculation

(1) Boolean weights

In Boolean weights, the presence or absence of a statistical feature in the text is collected. If the feature t_k existed in text d_j, w_{kj} to 1, otherwise 0, namely:

$$w_{kj} = \begin{cases} 1 \\ 0 \end{cases} \quad (3)$$

(2) Term frequency weights

Different from Boolean weighted which only depend on the presence or absence of a key, Term Frequency weight (TF) is based on word Frequency in the document to assign weights to Term. In term frequency weighting method, tf_{kj} is used to represent the frequency of feature t_k in text d_j, w_{kj} is defined as:

$$w_{kj} = tf_{kj} \quad (4)$$

(3) TF - IDF weights

$$w_{kj} = tf_{kj} * idf_k \quad (5)$$

In addition, the length of text also needs to be considered, this formula is obtained by normalizing the TFC:

$$w_{kj} = \frac{tf_{ik} * \log(M/n_k)}{\sqrt{\sum_{k=1}^{M} (tf_{ik} * \log(M/n_k))^2}} \quad (6)$$

Implementation and application of recommendation engine

3.1 Goals of recommendation engine service

The Internet has entered the era of web2.0, more and more information is in the Internet, when huge amounts of data is presented in front of the computer screen, not only it is difficult for users to pinpoint information needed, but also some of the less popular information are submerged in the ocean of information, which greatly reduces the utilization of information. With the increasing number of information, the data can't be used will be more and more.

In such an information age, the recommendation engine has become the effective tool to solve the problem of information overload. Recommendation engine can help users access to information closely related to their interests, even if he had never read one, the depth mining of the information recommended will also help users to get useful information.

3.2 Analysis of the recommendation engine

In the process of using film site, the general process is often done through simple search matching process of user and information, this method is single, and of low efficiency. Users often cannot simply by keywords to accurately describe their needs. For example, by "good movie" people are unable to get the accurate data, because each user's definition of good is not the same. the Internet search method for the large amounts of information has been unable to meet the requirements of information retrieval.

Summary

Information system and e-commerce system provides users with convenient access to information, the diversity of choice, but with the roof type development of information, Internet information overload phenomenon come, users get lost in the ocean of information, due to the large amount of information, users often can't find what they need accurately. Based on this background, the personalized recommendation engine arises at the historic moment. The current industry common recommendation technology study and research found many deficiencies of the recommendation technology. The technology based on content filtering recommendation technology, based on the collaborative filtering recommendation technology, etc. are usually used, they achieve the intelligent analysis and prediction through its own algorithm.

Research on Marine Fuel Boiler Drum water Level Model and Dynamic Analysis

Zhu Miao

Zaozhuang Vocational College of Science & Technology, TengZhou , 277500

Keywords: Drum water level, Steam flow, PID control

Abstract. This article first mathematical model of boiler water level, and then in MATLAB/ SIMULINK environment, the model simulation, and thus the dynamic characteristics of the model for analysis. Many real boiler parameters and variables, complex, by simplifying the modeling process, ignores some factors and variables, a simple model can be obtained results almost true fit. Boiler water level of the model established in considering the effect of steam flow and water flow of two factors.

Introduction

In this paper, the dynamic characteristics of marine fuel boiler drum level research. Many real boiler parameters and variables, complex, by simplifying the modeling process, ignores some factors and variables, a simple model can be obtained results almost true fit[1]. Boiler water level of the model established in considering the effect of steam flow and water flow of two factors, the simulation results show that the model is correct.

Drum level model and dynamic analysis

Many factors can cause changes in drum level, the main consideration is the change in steam flow and changes in water flow. After the dynamic equations can be simplified drum level[2]:

$$T_1T_2\frac{d^2h}{dt^2}+T_1\frac{dh}{dt}=\left(T_W\frac{du_W}{dt}+K_Wu_W\right)-\left(T_D\frac{du_D}{dt}+K_Du_D-T_P\frac{du_D}{dt}\right) \quad (1)$$

Where:

h—Height drum level; Tw—Constant water flow; T_D, T_P—The time constant steam flow;

Kw—Water flow amplification factor; K_D—Steam flow amplification factor;

D—Boiler steam flow; W—Boiler feed water flow; T_1, T_2—time constant.

Drum water level in the water flow effects of the dynamic characteristics

Assuming the steam flow to a certain value, the presence of water flow disturbance, then the equation is:

$$T_1T_2\frac{d^2h}{dt^2}+T_1\frac{dh}{dt}=T_W\frac{du_W}{dt}+K_Wu_W \quad (2)$$

For the Laplace transform formula are[3]:

$$T_1T_2S^2H(s)+T_1SH(s)=T_WSV_W(s)+K_WV_W(s) \quad (3)$$

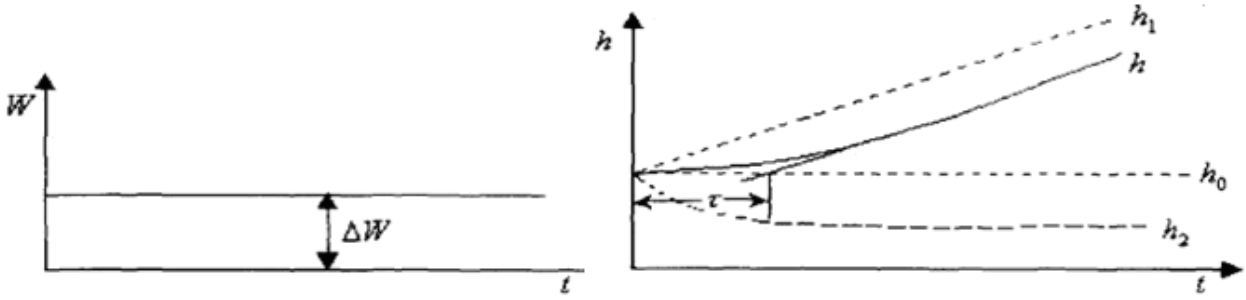
After the translation has drum level role in the transfer function of water flow:

$$G(s)=\frac{H(s)}{V_W(s)}=\frac{T_WS+K_W}{T_1S(T_2S+1)} \quad (4)$$

Assuming $\varepsilon = \frac{K_W}{T_1}$ was

$$G(s) = \frac{H(s)}{V_W(s)} = \frac{\varepsilon}{S(T_2S+1)} = \frac{1}{S} \cdot \frac{\varepsilon}{T_2S+1} \quad (5)$$

ε is when the unit boiler feedwater flow changes occur, the rate of change of drum water level when the boiler is running at full capacity, V if suddenly the water supply valve is closed, drum water level will continue to decline in the 50s if the drum water level dropped by 50mm , when the water flow from 100% open off a small 50% 50s time, drum level will reduce 25mm. From the above equation can be considered dynamic nature of drum water level in the water flow is determined by the role of a first-order inertia and an integral part of the composition[4], resulting curve to the water when the water level in the drum step change:



a) To a step change in water b) Under disturbance, drum level curve

Figure1 In step disturbance response curves drum water level changes

When the steam flow rate constant water flow step change occurs when the drum water level does not increase with the increase of water flow immediately, but began to increase after experiencing a delay. Draw h asymptote, it will be extended with no step change in water level occurs when the intersection, get the lag time; h1 change reflects the integral characteristics of drum level objects, h2 changes in response to the drum level object inertia, when the water started to increase the temperature of the incoming water is relatively low, reducing the temperature of the water in the original drum, the volume occupied by bubbles in soda mixture becomes smaller, making the drum water level drops. The total curve h can be regarded as obtained by adding curves h1 and h2.

Drum water level in the steam flow disturbance dynamic characteristics under

Water Drum assumed to remain unchanged when the steam flow changes are[5]:

$$T_1T_2\frac{d^2h}{dt^2} + T_1\frac{dh}{dt} = -(T_D\frac{du_D}{dt} + K_Du_D - T_P\frac{du_D}{dt}) \quad (6)$$

For the Laplace transform formula are:

$$T_1T_2S^2H(s) + T_1SH(s) = -[T_DSV_D(s) + K_DV_D(s) - T_PSV_D \quad (7)$$

After translation of the transfer function of steam flow disturbances drum level adjustment object:

$$G_D(s) = \frac{H(s)}{V_D(s)} = -\frac{(T_D-T_P)S+K_D}{T_1S(T_2S+1)} \quad (8)$$

$$G_D(s) = \frac{H(s)}{V_D(s)} = -\frac{1}{TyS} + \frac{Ky}{T_2S+1} \quad (9)$$

Drum water level can be obtained from the above equation steam disturbance adjust the dynamic characteristics of the object curve shown in Figure 2: Curve h can be divided into two parts, h1 and

h2, h1 is simply because water flow and steam flow imbalance makes the drum water level changes ; h2 changes when the steam flow inside the drum to pressure changes also followed, resulting in a "false water level." "False level" means the load increases, the air pressure inside the drum is reduced, so that the boiling point of water is reduced in the furnace, the temperature change does not occur immediately, and the water vapor tube within the drum strengthened soda mixture steam volume becomes large, so not only did not drum water level dropped because of increased steam flow, but the rapid rise of the situation.

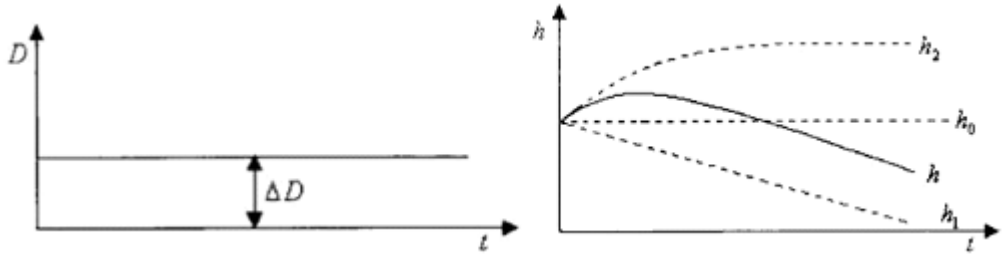


Figure 2 Curve step change occurred in the steam drum level when traffic

In MATLAB/Simulink for drum level in water flow and steam flow by the combined effect of the simulation, shown in Figure 3, so Ty = 50s, Ky = 1, deta = 0.02, T2 = 20s, water valves and steam valves are set linear, set every 1% change in the opening of the water flow and steam flow changes 0.4t / h, ie, the flow coefficient is 0.4. Enter the water flow to maintain 30% unchanged, steam flow from 30% in the 200s when 50% of the results in Figure 4 becomes available:

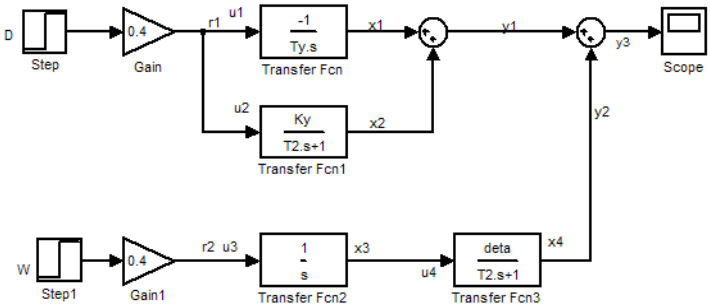

Figure 3 Drum level block diagram model simulation

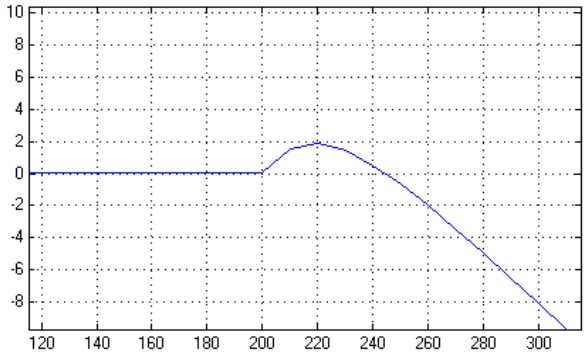

Figure 4 Water level increases the load curve

Drum level control

Drum level control system to adjust the following two ways:

l) single impulse water regulation system : Figure 5 , only the drum level signal as the basis for regulation , this regulation system structure is very simple , relatively large capacity for drum water level changes in the disturbance occurred more slowly, boiler " false water level " is not very serious , you can use a single impulse feedwater control system to meet production needs.

2) double impulse water regulation system : Figure 6, the boiler drum level signal as a master regulator signal , while the measured steam flow as a feedforward signal . As the introduction of the steam flow feedforward signal can reduce the bad effects of " false water level " of water regulation. When the change amount of steam , water flow adjusting the feedforward signal have a role in the same direction with changes in the amount of steam , which can be reduced or eliminated in the "false level " appears to make the amount of change in the opposite direction to the steam incorrect water flow regulation action. Steam flow occurred, the water valve will make its corresponding action, so to be able to reduce the amount of water and fluctuating water levels to a large extent , the reaction time is shortened . This adjustment method is suitable for the load conditions change frequently , requiring water pressure is relatively stable.

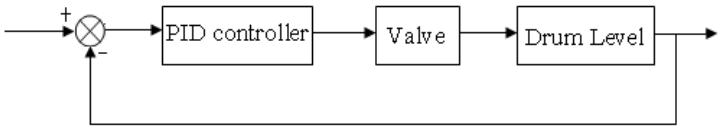

Figure 5 Feedwater regulator block diagram of a single impulse

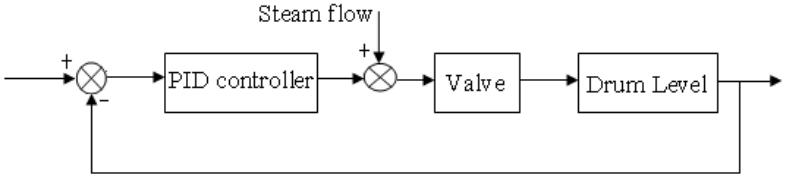

Figure 6 Double impulse water regulator block diagram

Conclusion

This paper analyzes the results can be seen, the boiler water level model can simulate a "false water level" effect when a sudden increase in the steam flow. In this chapter, also referred to this "false water level" situation can be single or double impulse love impulse method to counteract, as to the choice of which way the boiler can be determined according to the actual situation and production needs. Vapor pressure model can also be used as a model when the boost process that allows a value of zero to the steam flow.

Studies on broad-sense sample method in data mining

TANG Yan[1, a]

[1]College of Science, Northeast Agricultural University, Harbin 150030,China

[a] tangyan2014@yeah.net

Keywords: Small sample; Small sample evaluation methods; Small sample-support; Support Vector Machine; Data mining

Abstract. With the development of science and technology, people pay more and more attention to the reliability of the products, especially in some special field, such as aerospace, military products, and some products of high reliability and long life. As a part that runs through the whole life cycle of products, reliability test provides an important source of data for the design, batch production and residual life assessment of the product development. For some expensive, new products put into use, they are not quite little in amount, having the characteristics of small sample. In this case, how to use the existing data to predict product life, reliability of calculating the reliability of a product more accurately and other related parameters is particularly important.

Rough set theory and its application in data mining

This chapter studies key technical problems involved in the application of Rough Sets theory in data mining.

2. Basic concepts of rough set theory

Definition1: name relations system $K=(U,\overline{R})$ as a Knowledge base, in which $U=\{x_1,x_2,...,x_n\}$ is for object set (U is also called domain), [1] $\overline{R}$ is an equivalence relation on the set in U.

Definition 2: $a\in\overline{R}$, call binary group (U,a) as an approximation space of Pawlak, for any $X\subseteq U$, about lower approximation $\underline{a}(X)$ and upper approximation $\overline{a}(X)$ about X on approximation are respectively defined as:

$$\begin{aligned}\underline{a}(X)&=\{x\in U\mid[x]_a\subseteq X\}\\&=\bigcup\{Y\in U/a\mid Y\subseteq X\};\end{aligned}\tag{1}$$

$$\begin{aligned}\overline{a}(X)&=\{x\in U\mid[x]_a\cap X\neq\Phi\}\\&=\bigcup\{Y\in U/a\mid Y\cap X\neq\Phi\}.\end{aligned}\tag{2}$$

Definition 3: call $\alpha_a(X))$ and $\delta_a(X)$ as the approximation precision and roughness of X, a set of equivalent relationship of a, in which: $\alpha_a(X)=\frac{|\underline{a}X|}{|\overline{a}X|}$, $\delta_a(X)=1-\frac{|\underline{a}X|}{|\overline{a}X|}$ [2].

Obviously, $\delta_a(X)=\frac{|bn_a(X)|}{|\overline{a}X|}$, actually:

$$\delta_a(X)=1-\frac{|\underline{a}X|}{|\overline{a}X|}=\frac{|\overline{a}X|-|\underline{a}X|}{|\overline{a}X|}=\frac{|bn_a(X)|}{|\overline{a}X|}\tag{3}$$

If $|bn_a(X)|=0$, then on the down boundary of a, X is an empty, so the X is an accurate set and the roughness is 0; if $|\underline{a}X|=0$,[3] then the positive region of X is an empty set, showing that the X cannot be explained by a; it is all rough.

Information systems and decision table

Definition1: call $S=(U,\overline{A},V,F)$ as Information Systems, or database system, in which, U is called theory domain, $\overline{A}=\{a_1,a_2,...,a_m\}$ is set of properties, $a_j(j=1,2,...,m)$ called an attribute, V is the set of attribute value, $F=\{f_j \mid j\le m\}$, $f_j:U\times\overline{A}\to V$ is the function of the Information. Attribute a_j is certain relationship, also known as knowledge.

Definition 2: if $S=(U,\overline{A}=\overline{C}\bigcup\overline{D},V,F)$, in which, $\overline{C}\bigcap\overline{D}=\Phi$, $\overline{C}=\{c_1,c_2,...,c_k\}$ is the condition attribute set, $\overline{D}=\{d_1,d_2,...,d_h\}$ the decision attribute set, V is the set of attribute value, $F=\{f_j \mid j\le m\}$, $f_j:U\times\overline{A}\to V$ is the function of the Information, S is information system that has the function of decision performance. Such system tends to show in the form of table, the decision table. [4] It can be represented as $S=<U,\overline{C}\bigcup\overline{D}>$.

Definition3: set $(U,\overline{R},\overline{F})$ for information systems, be determined by $ind(\overline{R})$ as $U/ind(\overline{R})=\{A_i \mid A_i\in U/ind(\overline{R}),i\le t\}$, $t=\left|U/ind(\overline{R})\right|$. Use $f_l(A_i)(f_l\in F)$ to represent the value of the object of A_i property $a_l(a_l\in\overline{R})$, call $D(A_i,A_j)=\{a_l\in\overline{R}\mid f_l(A_i)\ne f_l(A_j)\}$ is set consist of identification attributes of A_i and A_j.

In fact, A_i and A_j are the most basic particles of knowledge $\overline{R}$, $D(A_i,A_j)$ said collection of all attributes to identify the most basic knowledge particle of A_i and A_j. Namely $\forall b=D(A_i,A_j)(b\in\overline{R})$, attribute b can tell the difference between A_i and A_j.

Small sample evaluation methods

Bayes method

The name of Bayes method origins from the British scholar whose name is Thomas Bayes (1702-1761). After his death, one of his article entitled "on solution on the problem of opportunity", the author puts forward a kind of inductive reasoning theory, then the scholars later summarized the theory, derive a system of statistical inference method, called the Bayes method.

Basic steps of the Bayes method

1. $p(x\mid\theta)$ said probability function of the whole depends on the parameters of θ, it said overall conditional probability function when the random variable θ given a value.

2. Obtain priori information parameters θ reflect, and use this information to determine the prior distribution $\pi(\theta\mid x)$.

3. Take two-step way to generate sample $x=(x_1,x_2,...,x_m)$. [5]First of all, generate a sample θ_0 from the prior distribution $\pi(\theta)$; then produce a set of samples observation values $x=(x_1,x_2,...,x_m)$ from a conditional distribution $p(x\mid\theta_0)$, which is joint density function of sample x, it contains the general information and sample information content, reflected in the form :

$$p(x\mid\theta_0)=p(x_1,x_2,...,x_m\mid\theta_0)=\prod_{i=1}^{m}p(x_i\mid\theta_0) \qquad (4)$$

4. Because θ_0 is still unknown, consider other information of value θ, thus get the joint distribution of sample x, in the same way, it is the synthesis of overall information, sample information and the priori information, its form is

$$h(x,\theta)=p(x\mid\theta)\pi(\theta) \qquad (5)$$

5. We will make the decomposition as in the following type

$$h(x,\theta)=\pi(\theta\mid x)m(x) \qquad (6)$$

Among them, $m(x)$ is the marginal probability functions of x, can also be expressed as:

$$m(x)=\oint_{\vartheta} h(x,\theta)d\theta=\oint_{\vartheta} p(x\mid\theta)\pi(\theta)d\theta$$

Thus we can get the following formula

$$\pi(\theta\mid x)=\frac{h(x,\theta)}{m(x)}=\frac{p(x\mid\theta)\pi(\theta)}{\oint_{\vartheta} p(x\mid\theta)\pi(\theta)d\theta} \qquad (7)$$

If θ is a discrete random variable, $\pi(\theta_i), i=1,2...$ can be used to show prior distribution, the posterior distribution gotten in this case is discrete, can be represented as:

$$\pi(\theta_i\mid x)=\frac{p(x\mid\theta_i)\pi(\theta_i)}{\sum_j p(x\mid\theta_j)\pi(\theta_j)}, i,j=1,2,... \qquad (8)$$

Bootstrap method

The Bootstrap method (also called self-help method), is a kind of augmented sample statistical inference method, raised by Stanford university professor Efron in 1977. When using the Bootstrap method, need not put forward other assumptions in advance, neither need not add new observation data, can only rely on the original data for statistical inference. This method simulates unknown distribution with the aid of existing sample data, it is the nature of a sampling process, can make full use of the samples on the maximum of the information itself contains. About the overall distribution there is no need to make assumptions, in the actual operation process, we use the self-help samples to estimate the unknown distribution of statistic characteristics, and these self-help samples on the basis of the test samples are generated by computer.

Bayes Bootstrap method

The Bootstrap method is to carry on the statistical inference directly by computing the sample data. Based on the Bootstrap method, Donald put forward the Bootstrap method, namely the random weighting method. Through sampling statistics, Bayes Bootstrap method is classified as a kind of simulation method. The Bayes Bootstrap method and the Bootstrap method both increase the capacity of the sample through the sample information "coattails", but because the Bayes Bootstrap method is for statistical inference of small sample, when statistics is inadequate, the method can improve the accuracy of statistical judgment

Summary

As a part throughout the product life cycle, reliability test provide the reference basis for the reliability of the product modeling, reliability design, reliability evaluation and reliability allocation and product acceptance, identification, and so on, therefore, the process of the result of reliability is particularly important. Value of small sample research not only depends on solving the small size sample, at the same time, it can also reduce the test cost, shorten the test cycle and improve product competitiveness.

Key words: Ocean sampling platforms; adaptive sampling; maximum differential algorithm; optimal sampling path.

Abstract. This paper presents a technique for adaptive ocean sampling using ocean sampling platforms equipped with multiple sensors. The virtual environment of 2D ocean sampling is established, so as to simulate the ocean sampling region by means of the sampling platforms. There are three important phases which can be written as collecting scientific data, drawing the sampling area, and utilizing the maximum differential algorithm (MDA) in ocean sampling. By analyzing the sampling data and using the maximum differential algorithm, the sampling platforms achieve the optimizing sampling path. The simulation results by adaptive ocean sampling of single sampling platform and multiple platforms show that the proposed approach is effective and feasible. This method can be applied to conduct the moving direction based on the ocean sampling platforms.

Introduction

With the rapid development of ocean technology, it is possible to acquaint the features of the ocean. J. Gao (2011) in [1], Q. Xiao et al., (2011) in [2] made mention that the biomimetic robotic fish can be used to check the ocean environment, exploit the undersea sources, relieve the trapped persons or other creatures and so on. Y. Wang (2011) in [3] introduced an unmanned surface vehicle for bathymetry as one of the basic platforms in ocean sampling, and studied the adaptive isobath tracking. C. Cannell (2004) in [4] designed a simulation tool to support the development of adaptive sampling algorithms for multiple autonomous underwater vehicles. Using limited time and optimal routes to sample more data, it can provide evidences for studying one certain feature of oceans. The key feature of these algorithms is that the sampling strategies are usually determined by sampling platforms based on data collected in real time. There are some researches about adaptive ocean sampling by some ocean experts or institutes. A. Alvarez(2007) in [5] designed combining networks of drifting profiling floats and gliders for adaptive sampling of the Ocean, and introduced the generation algorithm to optimize the path of the gliders.

Modeling of 2D Ocean Environment Sampling

In order to study some features of ocean effectively, such as the temperature and salinity which are usually diverse in different regions and depths, taking no account of the effect of ocean current, the environment of 2D ocean sampling is modeled (Ding Wang et al., 2009, in). Taking the salinity sampling as an example, the paper establishes the model of the environment of 2D ocean sampling which is shown in Figure 1. The distribution of salinity in this region can be written as follows:

$$z = f(x, y) \tag{1}$$

where: x, y is the relative longitude and latitude, respectively; z is the quantity of the salinity, which is denoted by the value of RGB in the figure. The ranges of x and y are both [0, 40]. The changes of different colors in this figure represent the quantity of the salinity, which can be seen in the side color bar.

Algorithm of Adaptive Sampling

Adaptive ocean sampling can be defined as equipping multiple sensors which can feasibly

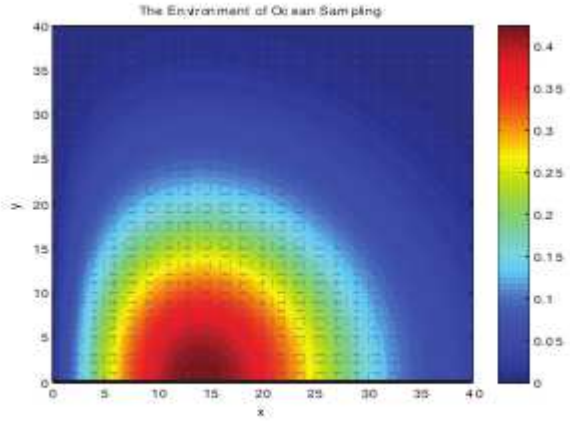

Fig. 1 The schematic of the environment of 2D ocean sampling.

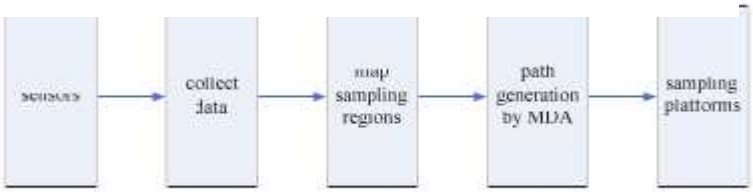

Fig. 2 The structure of the adaptive sampling algorithm.

collect, store and analyze the scientific data of ocean environment in real time, and then program the moving path by adaptive sampling algorithm, so as to acquire more information about the ocean in limited time. The structure of the adaptive sampling algorithm can be seen in Fig. 2. There are three important phases which can be described as collecting scientific data, mapping the sampling area and utilizing the maximum differential algorithm (MDA) in ocean sampling.

3.1 Scientific Data Collecting

Equipped with multiple sensors around the environment, sampling platform can collect the information of ocean. The distribution of sensors and the collecting data can be seen in Fig. 3. Blue triangle represents current path-points in the path, and the red dots show the unallowable path-point locations while the blue ones show the allowable path-point locations. Allowable set of path-points by taking into account the spatial constraints between the candidate point and the point that precedes it by one.

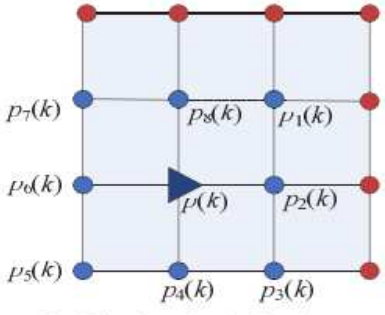

Fig. 3 The schematic of collect data.

n order to assimilate the process of the adaptive ocean sampling by sampling platform, we assume that the position of the platform is p(k) at time k, and the collect data position is (i)p k , i=1, 2,…, 8. The position of the platform can be written as:

$$p(k) = (x(k), y(k)) \quad k = 1, 2, 3, \tag{2}$$

where x(k) y(k) are the values of x and y coordinate at time k, respectively.

3.2 Sampling Regions Drawing

To simplify the moving state of the sampling platform, we divide the orientation discretely into eight orientations. The discrete orientation set is {UR, R, DR, D, DL, L, UL, U}, the U means up, the D means down, the R means right, and the L means left. Suppose the distance between adjacent grids is small enough ($\Delta l < \varepsilon$, $\varepsilon \geq 0$), we can consider that the platform will reach the point of pi(k) from p(k) per second. To make the salinity sampling adaptively by the sampling platforms, it is necessary to memorize the collecting data regions and analyze the data in real time. Then gain the variety of ocean salinity, and provide the path planning for the sampling platform properly. So we map the sampling regions through cells algorithm (Andrew A. Bennett et al., 2000, in), labeling four cells rounding the platform in real time, which can be seen in Figure 4. Sampling regions at time k can be written as:

$$C(k) = \{c(k), c(k), c(k)\, c(k)\}, k = 1, 2, 3, \quad (3)$$

where (1)c k is the cell rounding the sampling platform, i=1, 2, 3,4.As the motivation of the platform is continuous and uninterrupted, the sampling cells at time k+1 must intersect with the cells at time k, presented as $C(k)\, C(k+1) \neq \Phi$. In order to avoid the repeated sampling of the same region, there should be differences

between C (k)and C (k + n), which can be presented as $C(k)\, C(k+n) \neq C(k)$and $C(k)\, C(k+n) \neq C(k+n)$. So we can make sure that the motivation is continuous and unrepeated.

3.3 Path Generation by MDA

In the adaptive ocean sampling, it is crucial to make the path planning to the platform. The sampling platform can move properly directed by adaptive ocean sampling algorithm, so as to collect more useful scientific data in shortest time, and avoid repeated collecting data in the same region. To achieve the motivation path of the sampling platforms, the MDA is proposed. This algorithm will make the sampling platforms continuously move to the beneficial orientation, which has the maximum difference in salinity among eight directions. So the maximum difference formula is introduced, which can be written as:

(a). Initialize the position of the sampling platform and the sampling parameters;

(b). Collect data in the position of the core of the sampling platform and the rounding positions, and map the sampling regions;

(c). Judge the sampling regions whether it can satisfy our meet or not. If “Yes”, then over; if “No”, then continue;

(d). Calculate the maximum difference parameter D(k), and gain the moving direction by the sampling platform;

(e). Move the sampling platform to the designed position, and then return (b).

Conclusions

In this paper, the environment of 2D ocean sampling has been established in order to simulate the ocean sampling region using the sampling platforms. By accurately analyzing the collecting data and the current data, the sampling platforms can move availably directed by MDA and gain the optimizing sampling path. Simulation results by adaptive ocean sampling of single sampling platform and multiple platforms have indicated the effectiveness and feasibility of the proposed approach, which can be greatly used in the application of ocean sampling. Future research will be aimed at considering the complexity and uncertainty of the ocean environment in order to make the approach more precisely.

Keywords: Parameter estimation, Recursive least squares algorithm, Switching function, Wiener system.

Abstract. This paper proposes a recursive least squares algorithm for Wiener systems. We use a switching function to turn the modelof the nonlinear Wiener systems into an identification model, then propose a recursive least squares identification algorithm toestimate all the unknown parameters of the systems. Finally, an example is provided to show the effectiveness of the proposed algorithm.

1 Introduction

Nonlinear systems arise widely in process industries, andidentification of such systems has been an active researcharea for a long time. There exists three mature methods onidentification of these nonlinear systems: the stochastic gradient(SG) algorithm [1–3], the recursive least squares (RLS)algorithm [4–6] and the iterative algorithm [7–9]. The RLSalgorithm has quicker convergence rate than the SG algorithm[10].

In this paper, we deals with a Wiener system which is shown in Figure 1 and is expressed as follows:

$$x(t)=\frac{B(z)}{A(z)}u(t), \tag{1}$$

$$y(t)=f(x(t))+v(t). \tag{2}$$

where $y(t)$ is the system output, $x(t)$ is the unknown innervariables, $u(t)$ is the system input, and $v(t)$ is a stochasticwhite noise with zero mean, and $A(z)$ and $B(z)$ are polynomials in the unit backward shift operator [$Z^{-1}y(t)=y(t-1)$] and

$$A(z) := 1 + a_1z^{-1} + a_2z^{-2} + \cdots + a_nz^{-n},$$

$$B(z) := b_1z^{-1} + b_2z^{-2} + \cdots + a_nz^{-n}.$$

The function $f(x(t))$ is a preload nonlinearity and can be expressed as

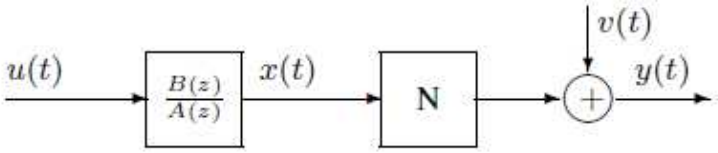

Fig. 1: The Wiener model

$$f(x(t)) = \begin{cases} x(t) + m, & x(t) > 0, \\ 0, & x(t) = 0, \\ x(t) - m, & x(t) < 0, \end{cases}$$

where m and -m are the preload points.

By using a switching function, the model of the Wiener systems be changed to an identification model, then based on the derived model, a RLS algorithm is presented to estimate all the unknown parameters. Briefly, the paper is organized as follows. Section 2 describes the nonlinearities and studies estimation algorithms for the Wiener system. Section 3 provides an illustrative example. Finally, concluding remarks are given in Section 4.

2 The nonlinearities and the estimation algorithms

Let "$A =: X$" or "$X =: A$" stand for "A is defined as"; the norm of a column vector X is defined as $\|X\|^2 := tr[X^T X]$; the superscript T denotes the matrix transpose.

Introduce a sign function,

$$\mathrm{sgn}[x(t)] := \begin{cases} 1, & if\ x(t) > 0, \\ 0, & if\ x(t) = 0, \\ -1, & if\ x(t) < 0. \end{cases}$$

The function $f(x(t))$ be expressed as

$$y(t) = f(x(t)) + v(t) = x(t) + m\,\mathrm{sgn}(x(t)) + v(t). \tag{3}$$

Then the Wiener model can be rewritten as

$$x(t) = \frac{B(z)}{A(z)}u(t), \tag{4}$$

$$y(t) = x(t) + m\,\mathrm{sgn}(x(t)) + v(t). \tag{5}$$

Define the parameter vector θ_1 and the information vector $\varphi_1(t)$ as

$$\theta_1 := [a_1, a_2, \cdots, a_n, b_1, b_2, \cdots, b_n]^T \in R^{2n} \tag{6}$$

$$\varphi_1(t) := [-x(t-1), -x(t-2), \cdots, -x(t-n), u(t-1), u(t-2), \cdots, u(t-n)]^T \in R^{2n}, \tag{7}$$

gets

$$x(t) = \varphi_1^T(t)\theta_1,$$

$$y(t) = \varphi_1^T(t)\theta_1 + m\,\mathrm{sgn}(x(t)) + v(t).$$

Define the parameter vector θ_2 and the information vector $\varphi_2(t)$ as

$$\theta_2 := [a_1, a_2, \cdots, a_n, b_1, b_2, \cdots, b_n, m]^T \in R^{2n+1}, \tag{8}$$

$$\varphi_2(t) := [-x(t-1), -x(t-2), \cdots, -x(t-n), u(t-1) \quad u(t-2), \cdots, u(t-n), \mathrm{sgn}(x(t))]^T \in R^{2n+1}, \tag{9}$$

then

$$y(t) = \varphi_2^T(t)\theta_2 + v(t).$$

Using the following RLS algorithm to estimate the parameter vector θ_2 in (8):

$$\hat{\theta}_2(t) = \hat{\theta}_2(t-1) + P(t)\varphi_2(t)e(t), \tag{10}$$

$$e(t) = y(t) - \hat{\theta}_2^T(t-1)\varphi_2(t), \tag{11}$$

$$\varphi_2(t) = [-x(t-1), -x(t-2), \cdots, -x(t-n), u(t-1), \quad u(t-2), \cdots, u(t-n), \mathrm{sgn}(x(t))]^T, \tag{12}$$

$$P(t) = P(t-1) - \frac{P(t-1)\varphi_2(t)\varphi_2^T(t)P(t-1)}{1 + \varphi_2(t)P(t-1)\varphi_2(t)^{-1}},$$

$$P(0) = 10^6 I. \tag{13}$$

Because the information vector in (12) [that is $\varphi_2(t)$] contains the unknown inner variables $x(t-i)$, the above RLS algorithm in (10) cannot be applied to estimate θ_2 in (8).The solution is to use the auxiliary mode identification idea in [11]: the unknown variables are replaced with their estimates or with the outputs of the auxiliary model. Define

$$\hat{x}(t) = \hat{\varphi}_1^T(t)\hat{\theta}_1(t), \tag{14}$$

$$\hat{\varphi}_1^T(t) := [-\hat{x}(t-1), -\hat{x}(t-2), \cdots, -\hat{x}(t-n), u(t-1), \quad u(t-2), \cdots, u(t-n), \mathrm{sgn}(\hat{x}(t))], \tag{15}$$

when $\hat{\theta}_i(t),(i=1,2)$ is the estimate of θ_i, $\hat{\varphi}_i(t)$ is the estimate of $\varphi_i(t)$ and $\hat{x}(t)$ is the estimate of $x(t)$. We can obtain a auxiliary model based RLS (AM-RLS) algorithm as:

$$\hat{\theta}_2(t)=\hat{\theta}_2(t-1)+P(t)\hat{\varphi}_2(t)e(t), \tag{16}$$

$$e(t)=y(t)-\hat{\theta}_2^T(t-1)\varphi_2(t), \tag{17}$$

$$\hat{x}(t)=\hat{\varphi}_1^T(t)\hat{\theta}_1(t), \tag{18}$$

$$\hat{\varphi}_1^T(t):=[-\hat{x}(t-1),-\hat{x}(t-2),\cdots,-\hat{x}(t-n),u(t-1), u(t-2),\cdots,u(t-n)]^T, \tag{19}$$

$$\hat{\varphi}_2^T(t):=[-\hat{x}(t-1),-\hat{x}(t-2),\cdots,-\hat{x}(t-n),u(t-1), u(t-2),\cdots,u(t-n),\mathrm{sgn}(\hat{x}(t-1))]^T, \tag{20}$$

$$,P(t)=P(t-1)-\frac{P(t-1)\hat{\varphi}_2(t)\hat{\varphi}_2^T(t)P(t-1)}{1+\hat{\varphi}_2(t)P(t-1)\hat{\varphi}_2(t)^T},$$

$$P(0)=10^6 I. \tag{21}$$

The steps of computing the parameter estimation vector $\hat{\theta}_2(t)$ by the RLS algorithm are listed in the following.

1) Let $t=1,\hat{\theta}_2(0)=1/p_0, and P(0)=p_0 I$ with 1 being a column vector whose entries are all unity and $p_0=10^6$.

2) Let $y(-j)=0,u(-j),x(-j)-0,\ j=0,1,2,\cdots,n-1$, and give a small positive number ε.

3) Collect the input data $\{u(t),y(t)\}$.

4) Form $\hat{\varphi}_1(t)$ and $\hat{\varphi}_2(t)$ by (19) and (20).

5) Compute $\hat{x}(t)$ by (18).

6) Compute $e(t)$ and $P(t)$ by (17) and (21) respectively.

7) Update the parameter estimation vector $\hat{\theta}_2(t)$ by (16).

8) Compare $\hat{\theta}_2(t)$ and $\hat{\theta}_2(t-1)$: if $\left\|\hat{\theta}_2(t)-\hat{\theta}_2(t-1)\right\|\le\varepsilon$, then terminate the procedure and obtain the $\hat{\theta}_2(t)$; otherwise, increase *t* by 1 and go to step 3.

3 Example

Consider the following nonlinear system

$$x(t)=\frac{B(z)}{A(z)}u(t)+v(t),$$

$$y(t)=x(t)+0.05\,\mathrm{sgn}(x(t)),$$

$$A(z)=1+a_1z^{-1}+a_2z^{-2}=1+0.38z^{-1}+0.31z^{-2},$$

$$B(z)=b_1z^{-1}+b_2z^{-2}=0.64z^{-1}+0.70z^{-2},$$

$$\theta_2=[a_1,a_2,b_1,b_2,m]^T$$

$$=[0.38,0.31,0.64,0.70,0.05]^T.$$

Here, $\{u(t)\}$ is taken as a persistent excitation signal sequence with zero mean and unit variance, and $\{v(t)\}$ is taken as a white noise sequence with zero mean and variance $\sigma^2=0.10^2$. Applying the RLS algorithm to estimate the parameters of this example system, the parameter estimates and their errors are shown in Tables 1.

4 Conclusions

An approach to identify a Wiener system with preload nonlinearity is presented in this paper. By using a switching function, the model of the nonlinear system be turned into an identification model,

then a RLS algorithm is proposed to estimate all the parameters of the system. The simulation results verify the proposed method.

Keywords: vertical handoff, QoS evaluation, Analytic Hierarchy Process(AHP）, Cost function.

Abstract. In the next generation of heterogeneous wireless network environment, to meet the network requirements of diverse services， we propose a vertical handoff decision algorithm based on QoS evaluation that refine the handover unit to services. The proposed algorithm consider the needs of the services, network conditions, user preferences and other factors, and makes Analytic Hierarchy Process (AHP) and cost function combine to choose the target network that is best meet the requirements of services . Comparing with the vertical handoff decision based on RSS, simulation results show that the proposed method can take full account of the different QoS requirements of various services types to choose the appropriate network, and would not cause performance degradation.

Introduction

With the rapid development of wireless communication technology, all kinds of wireless access technology emerge in endlessly constitute the ubiquitous wireless heterogeneous network [1,2]. In order to achieve the user's session continuity and seamless across heterogeneous networks vertical handover has become one of the important issues need to be resolved. Literature [3] focus on how to reduce energy consumption of the terminal, as well as to determine the appropriate time to switch trigger. Literature [4] proposed network selection algorithm based decision function, comprehensive survey network characteristics, user requirements and terminal status and other conditions. However, most studies are based on terminal as the smallest handover unit, the entire terminal to switch to the target network by comparing network performance evaluation function or access cost function. Due to different types of services, this may cause the selected network may not be able to meet a good QoS requirements of each service. This paper consider services, network, user terminal and other factors, makes Analytic Hierarchy Process (AHP) and cost function combine to choose the target network, propose a vertical handoff decision method based on QoS evaluation. The advantage of the presented handoff decision algorithm has been proved by the simulation.

QoS Evaluation Based Vertical Handoff Decision Algorithm

Analytic Hierarchy Process.

1) The structuring hierarchy: In-depth analysis of different factors in the practical problems，To construct of these Related factors into a hierarchy according to the attributes [5]：The goal level as the top level of the structuring hierarchy generally have a factor； alternative level is the lowest level； criterion level is in the middle，generally have multiple factors，When too many factors that will break out sub-criterion level. QoS evaluation of different services to QoS parameter, so using AHP method to calculate the relative weight of each parameter. Our goal level is the optimal network based on services; alternative level is WLAN/UMTS network. When designing the criterion level, this paper will consider five main QoS parameters: Delay, Bandwidth, Packet-loss Rate, Price, Security.

2) Establish judgment matrix：Judgment matrix [6] constructed with the pair wise comparisons method and Table 1. $x_1 x_2 \cdots x_n$ are factors of the criterion level, choose any two of them x_i and x_j compare pair wise according to their levels of influence. The comparison result r_{ij} are presented in judgment matrix $R = (r_{ij})$;and $r_{ij} r_{ji} = 1$.

Table 1 Scale of importance

Intensity	Definition
1	Equal importance
3	Moderate importance
5	Strong importance
7	Very strong importance
9	Extreme importance
2，4，6，8	Intermediate values

3) Calculation of the relative weights: normalize the vector, get $(w_1, w_2, ..., w_n)$ as evaluation parameters of weight.

$$\overline{w_i} = \sqrt[n]{\prod_{j=1}^{n} r_{ij}} \text{ (i=1,2, ... ,n)} \tag{1}$$

$$w_i = \frac{\overline{w_i}}{\left(\sum_{i=1}^{n} \overline{w_i}\right)} \tag{2}$$

4) Consistency check: In order to avoid potential inconsistency, we introduce consistency index (CI) and random index (RI) [6].

$$CI = \frac{\lambda_{\max} - n}{n-1} = \frac{-\sum_{k \neq \max} \lambda_k}{n-1} \tag{3}$$

$$CR = {CI}/{RI} \tag{4}$$

If $CR \le 0.10$,the inconsistency is considered acceptable, otherwise the judgment Matrix needs to be revised. We can get various values of RI from Table 2.

Table 2 Value of random consistency index

Criteria	1	2	3	4	5	6	7	8	9	10	11	12
RI	0	0	0.58	0.9	1.12	1.24	1.32	1.41	1.45	1.49	1.52	1.56

Parameter Standardization. This paper consider the five kinds of QoS parameters: Delay, Bandwidth, Packet-loss Rate, Price, Security. Their value standards are different, if use them directly, the result of the cost function is meaningless. So in order to obtain reasonable network cost, cost, we need to standardize the parameters. These parameters can be divided into real-benefit type (Bandwidth) ,real-cost type(Delay, Packet-loss Rate),language type(Price, Security).For real-benefit type, the larger the parameter value, the better the network performance. But for real-cost type, the larger ,the worse [7].Obviously these two kinds of parameters must adopt different methods of standardization. We define b_n^x as standardized value of parameter x in network n, $x_{\max}$ and $x_{\min}$ as upper limit and lower limit of parameter x.

For real-benefit type:

$$\begin{cases} b_n^x = {(x - x_{\min})}/{(x_{\max} - x_{\min})}, when(x_{\min} < x < x_{\max}) \\ b_n^x = 1, when(x \le x_{\min}) \\ b_n^x = 0, when(x \ge x_{\max}) \end{cases} \tag{5}$$

For real-cost type:

$$\begin{cases} b_n^x = {(x_{\max} - x)}/{(x_{\max} - x_{\min})}, when(x_{\min} < x < x_{\max}) \\ b_n^x = 0, when(x \le x_{\min}) \\ b_n^x = 1, when(x \ge x_{\max}) \end{cases} \tag{6}$$

Language type can not be represented by exact number， they need to be quantified. This article adopts the method of literature [8],then follow the above formula to standardize, the result are listed in the Table 3.

Table 3 Standardized value of language type

	Security	Price
UMTS(Standardized value)	Relatively good（0.6）	general（0.3333）
WLAN(Standardized value)	general（0.4）	low（0.6666）

Handoff Decision Process. After obtaining the parameters weights and standardized values, we need to complete the network selection. Because the traditional cost function can not reasonably choose the network according to services requirements, we propose a cost function based on QOS evaluation .We define F_s^n as the QOS evaluation value of the network n for the service s, w_s^x denotes the weight of parameter x for the service s：

$$F_s^n = \sum_x w_s^x b_n^x \tag{7}$$

Finally, network obtain highest QOS evaluation value is the optimal target network:

$$f_{best}^s = \{n \Big| \max_{1 \le n \le N} F_s^n\} \tag{8}$$

Simulation and Results

In this paper, simulation tool are developed using NS-2 .our simulation scenario involves two wireless access networks UMTS and WLAN. Because NS-2 simulation tool integrates no UMTS module, we use the existing the WLAN module for the UMTS simulation .Choose the interactive service as representative from the classification of 3GPP for services [9].Five Qos evaluation parameters considered in this paper: Delay and Packet-loss rate, Bandwidth, Security, Price, Their weights were 0.1059, 0.2605, 0.5263, 0.0648, 0.0425 according to AHP .In order to evaluate the performance of the handoff algorithm, we designed handoff scene: The center of the WLAN is on the x axis, coordinate is(100,0);the center of the UMTS is also on the x axis, coordinate is(200,0).Terminal from the origin moves along the x axis at a speed of 1 m/s, enter the WLAN network coverage area in 50s and lefe in150s.Terminal will be scanned once every two seconds with uniform sampling method. For more realistic performance evaluation, background traffic is added in the simulation, set the link delay dynamically, thus QoS parameter values of WLAN and UMTS dynamically changes. Fluctuations of Bandwidth and Delay in WLAN and UMTS as shown in the Figure 1and 2.

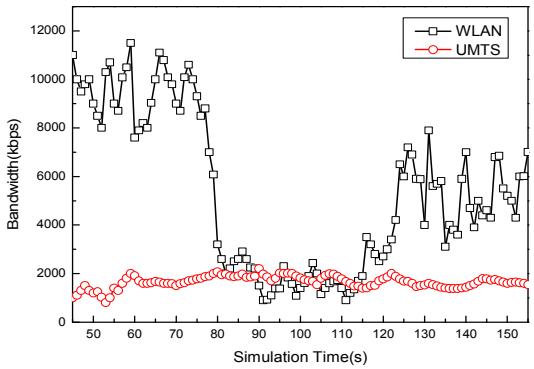

Fig.1 Fluctuations of Bandwidth

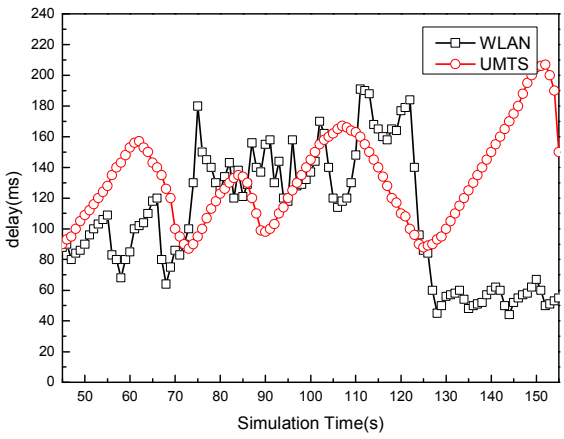

Fig.2 Fluctuations of Delay

We evaluated our proposed QoS evaluation based algorithm by comparing it with the RSS based algorithm. As illustrated in the Figure 3,except for some handover caused by entering and leaveing coverage of the wlan, mobile terminal gets handover at 91s and 113 s respectively; Combined with Figure 1 and 2 ， during 90s-113s average available bandwidth of the WLAN is smaller than the UMTS, in order to meet the needs of the business，switching to the UMTS. Although real-time performance of the UMTS is better than that of the WLAN during 73s-124s ,the interactive service was not sensitive to time delay, so the impact on handoff is smaller. For the RSS based algorithm，mobile terminal gets handover from UMTS to WLAN at 57.4s,back to the UMTS at 142.6s,Mobile terminal has been in the WLAN during 57.4s-142.6s.The RSS based algorithm dones't consider the service requirement for QoS.

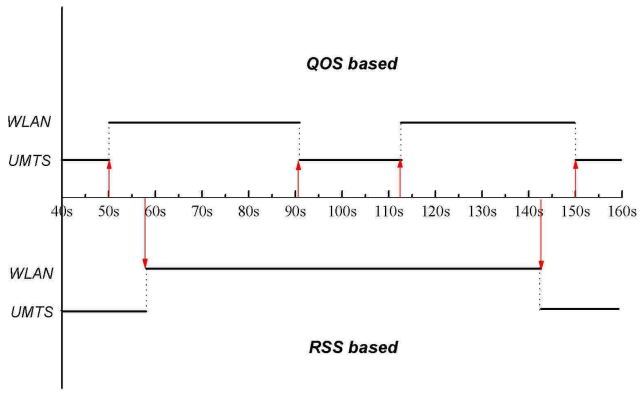

Fig.3 Handoff process of the interactive service comparison

For interactive class business, The most important performance index is throughput. as shown in the Figure 4,the vertical handoff decision method proposed in this paper can obtain higher average throughput than RSS based method.

From the above simulation data, in this paper a QoS evaluation based handoff algorithm is proposed that can take full account of the different QoS requirements of various services types, use the QoS evaluation of service to rank the candidate networks, and will not result in lower performance.

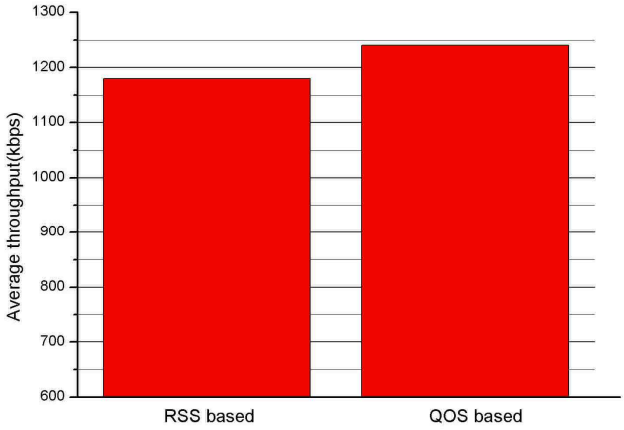

Fig.4 Average throughput of the interactive service comparison

Conclusion

The proposed vertical handoff decision algorithm based on QoS evaluation, can take full account of the different QoS requirements of various services types，adopt Parameters standardization method to obtain reasonable QoS parameter values, and makes Analytic Hierarchy Process and cost function combine to choose the target network that is best meet the requirements of services . Simulation result shows，a QOS requirements of services based Vertical handoff algorithm proposed in this paper, considering Multiple parameters, can be very effective for the selection of the optimal network according to QOS requirements of services ,and will not result in lower performance.

slxylyw@163.com

Keywords: Chaotic system; Wavelet lifting; DCT coefficients；Compressed video

Abstract. The scrambled watermark is embedded in DCT coefficients of low-frequency sub image with the Brightness Component of original color image after lifting wavelet transformation. Before embedding the watermark, the image confusion method is used to eliminate the space correlation of the pixels and improves the security and robustness. The results showed that the algorithm is easy to carry out with the real-time request of video watermarking.

Introduction

In recent years, video watermarking has been attracted consumers attention and interesting, which is an effective scheme for digital media copyright protect and content authorization of digital video products. Much more Excellent algorithms of watermarking are proposed with the technology of video watermarking development in recent years[1-4],which can be classified into two categories :spatial domain and frequency domain based.Video watermarking algorithm is complicated and difficult comparing with image watermarking, Recently, the precise human vision system model has not been established,whosever it was attacked by any way than image watermarking for video stream, such as, recombining frame[5],falling frame[6] ,etc. The real-time should be considered in Video watermarking algorithm just as [7],otherwise the watermarking will not achieve the purpose.

A video digital watermarking algorithm based on chaotic maps was proposed, watermark signal was embeded continuously in some image frames of video in order to weak the falling frames. The component lightness of image frames was resolved to integral wavelet, then the Low-frequency approximation point DCT coefficient is quantified and modulated, watermarking signal were scrambled and chaotic encrypted before embedded in image frames in the process of quantization. The result showed that the algorithm can improve the security and robustness in video image frames.

The rest of the Letter is organized as follows, Section 2 describes chaotic maps and wavelet lifting in image watermarking scrambling ,The video watermarking scheme based on chaotic systems is proposed in section 3.Simulation result are discussed in section 4 and section 5 concludes the Letter.

Chaotic maps

To enhance the security and robustness of watermarking, image frames were scrambled transfered and disorganized the original pixel coordinate to subtractive the space correlation.The common image scrambling such as: chaotic scrambling, magic transformation , Arnold transformation.etc. The video image watermarking was scrambled in this paper with chaotic maps. Chaotic maps is unpredictable but regular, it is quite sensitivity for initial parameter lead to emerge the chaotic sequence of completely different and irrelevant in little time. The Logistic maps and Hybrid maps was applied widely [7].To determine the bit of host image pixels in watermark embedding, chaotic map is used in the approach. A commonly used one is the logistic map, which is described by:

$$X_{n+1} = \mu X_n (1 - X_n) \tag{1}$$

Where $X_{n+1} \in (0,1)$ $\mu \in (0,4)$ .When $\mu > 3.5699456$,the sequence iterated with initial value X_0 is chaotic, different sequence will be generated with different initial values[8].

A short compressed video was decomposed to 168 frames, whose frame size is 256*256, any frame was tested with watermarking embedding and extraction in this experiment. If the original video image frame $p(x,y)$ is gray image of $M \times N$ size and the watermarking image is a binary image $w(x,y)$ of $i \times j$ size($i = M/16, j = N/16$).

(1) Watermark embedding

Watermark embedding algorithm can be described as follow.

Step 1: The original carrier image is brightened with color space transformation before watermarked P_Y .

Step2: P_Y is decomposed with a one level lifting wavelet and obtained subimage P_L . The low pass subimage is divided into 8×8 sub blocks $P_{LB}(x,y)$, $x = 1,2,\cdots M; y = 1,2,\cdots N$.

Step 3: The discrete cosine transform(DCT) is employed to every sub block $D_{x,y}$ and its DC coefficients $d(x,y)$ are used to embed watermark information.

The quantitative value $\delta(x,y)$ of each $d(x,y)$ is given by: $\delta(x,y) = \text{round}(d(x,y)/\lambda)$, while round(·) is the round off function, and λ is the predetermined quantization step. The original watermark image is denoted as w and the scrambled watermark image is denoted as W_a .

If $\text{mod}((\delta(x,y) + W_a(x,)y),2) = 1$, then $\bar{d}(x,y) = \lambda(\delta(x,y) - 0.5)$,

else $\bar{d}(x,y) = \lambda(\delta(x,y) + 0.5)$.

Step 4: The DC coefficients $d(x,y)$ is replaced by $\bar{d}(x,y)$ in each sub block. Then the modified sub blocks are obtainecd by IDCT, and the low pass subimage is formed. The watermarked image is got by inverse wavelet transform. The single frame was lightened the color and saturation component to convert RGB ,the process embedding finished.

(2)Watermark extraction

Watermark extraction is just the inverse process of the above embedding algorithm.

Step1 The original extraction image P' is brightened with color space transformation before embedded watermark, marked P_Y .

Step2 P_Y is decomposed with a one level lifting wavelet, and obtained subimage P'_L . The low pass subimage is divided into M×M sub blocks $P'_{LB}(x,y)$, $x = 1,2,\cdots M; y = 1,2,\cdots N$.

Step3 Calculated the quantitative value $\mu'(x,y) = floor(dc'(x,y)/\delta)$, Corresponding watermark information was decided according to $\mu'(x,y)$.

Step 4 The watermark w' is abstracted from W'_a by inverse scrambled according to the keys.

Simulation result

Appropriate quantization step δ and coefficient β are selected in simulation process. The peak signal-to-noise ratio (PSNR) is used to establish the difference between the watermarked image frame and original image frame. Generally, the greater the PSNR value is, the watermark transparency is better. The similarity measure between the original and extracted watermarks is given by:

$$SIM = \frac{\sum_x \sum_y W(x,y)W'(x,y)}{\sum_x \sum_y W^2(x,y)} \tag{2}$$

The original image frame and original watermark image are shown in Fig. 1. Watermarked image frame and extracted watermark image are shown in Fig. 2. The watermark information is

embedded in some video frames. The PSNR values between 36 and 40, and these values showed the transparency of this method.

Fig. 1 Original image frame and watermark

Fig. 2 Watermarked image frame and extracted

Watermark information can be extracted when random frame lost occurred since the watermark image is multi-embedded in some frames.Fig. 4 shows the extraction result by “Gaussian noise” with zero mean-value and 0.002 variance and “Salt and Pepper” noise with 0.02 density.

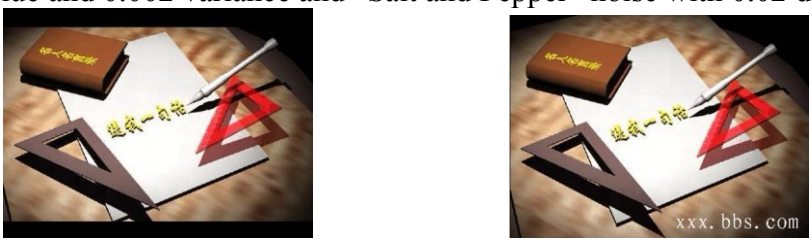

Fig.3 Cropping and filled with zero pixels and characters attack

Fig. 3 shows the result by cropping and filled with zero pixels and characters attack.The value of SIM with video frames watermarked is shown in Fig.5.

Fig.4 Watermarked frames with noise attacked test

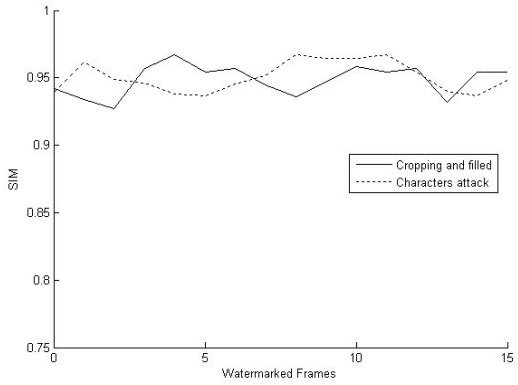

Fig.5 Cropping and filled and characters attack test

Conclution

Video watermarking is difficult in real-time and algorithm complexity comparison with image in digital watermarking technology .In this Letter ,video digital watermarking algorithm based on wavelet lifting quantization of DCT coefficients is proposed, the watermarking information with chaotic maps was embedding in video frames. One maps is used to encrypt the embedding position and another one is used to determine the pixel bit for embedding in host image. Simulation have confirmed that this new scheme is fair robustness and invisibility against various signal processing operation and geometric attacks. It is also more convenient base on integer wavelet lifting and easy to hardware implementation.

Keywords: Zero watermarking; Enhanced bit-plane; Cellular neural network

Abstract. Traditional watermark embedding introduces inevitably some perceptible quality degradation of the host image. Another problem is the inherent conflict between imperceptibility and robustness. However, the zero-watermarking technique can extract some essential characteristics from the host image and use them for watermark registration and detection. The original image was decomposed into series of multiscale and directional subimages after lifting wavelet transformation (LWT). The high order bit-plane of low-frequency subimage and watermark image are inputs of the cellular neural network(CNN), and the zero-watermarking registration image is the output. To investigate and improve the security and robustness, the original watermark and registration image are scrambled or encrypted. The watermark image can be extracted from the secret image. This algorithm is simple and robust. The proposed method is also simple for hardware realization.

Introduction

The development of network and multimedia technology makes it convenient to access the multimedia information. These technologies bring people many conveniences but they also bring us some large side effects. The problem of multimedia copyright protection becomes increasingly serious. With the development of the internet of things and cloud computing, this problem becomes more urgent. As an effective method for the protection of digital property rights, content authentication and secret communication, digital watermark technology becomes an active research area.

Researchers proposed a lot of methods. In most traditional digital watermarking algorithms, watermark information is embedded in the spatial or transform domain of the carrier image. The LSB [1] and Patchwork methods[2] are typical watermarking methods of spatial domain. Transform domain algorithms are most based on DCT, DFT, DWT [3,4,5], Fourier-Mellin transform[6], Radon transform[7] and so on. A good digital watermarking algorithm should have some basic characteristics, such as: robustness, invisibility, large embedding capacity, lower computational complexity and so on. However, it is also a challenging problem to completely achieve these requirements of algorithms. Literature[8,9] proposed without modifying the original image of zero-watermarking technique including registration and authentication. In the registration process, the algorithm constructed watermark with being protected of image characteristics, and stored in a centralized authentication center. In the authentication process, watermark information is recovered with recognition images and the data of authentication center. In the literature[8], it has the high computational complexity in calculating Higher-Order Statistics. In the literature[9], the zero-watermarking was implemented in DWT domain. The coefficients of image after traditional wavelet transform are floating point numbers; this is a negative factor in many applications. The lifting wavelet transform improves the structure of traditional wavelet and overcomes some shortcomings of it. Its coefficients are integers. It reduces the complexity of algorithm, and is convenient for hardware realization.

This paper proposed a robust image watermarking method using lifting wavelet transform and enhanced bit-plane. The algorithm first gains the high order bit-plane of low-frequency subimage after lifting wavelet transform. Then the high order bit-plane and the scrambled watermark image are

inputted into CNN network, and the encrypted image is produced. Experiments show that the method can get a good visual effect and is robust to plus-noise, filtering, JPEG compression, and cropping attack.

Cellular Neural Networks

L.O.Chua et al. putted forward the Cellular Neural Network (CNN) that simulated the non-liner and real-time speed array processor of VSLI[10]. The model of a two-dimensional CNN is described which compose of basic processing units called cells. Each cell is connected to its neighboring ones, therefore only the adjacent cells can interact directly with each other. CNN parallel processor can implement difference function of image processing.

Enhanced Bit-plane

For an image, each bit can be regarded as a binary plane or a bit-plane. For example, the pixel value of an eight bits gray image can be expressed as the following:

$$f(x,y) = a_7 \times 2^7 + a_6 \times 2^6 + \cdots + a_0 \times 2^0 \tag{1}$$

where f(x, y) indicates gray image, and the value of a_k is 1 or 0. The matrix which is formed by the pixel of the *k*th bit is $a_k(x,y)$. That is, the *k*th bit-plane. The level of the *k*th position is 2^k. Therefore, this 8-bits gray image can be seen that it is formed by eight binary images, in which each side only describes part of the information.

High order bit-planes represent the basic data of the picture, while low order represent the details of an image and even noise. Here we choose high order bit-plane to ensure the robustness of the watermarking. But the small change of the pixel value can make the great changes to the bit-plane. Therefore, it needs to change the bit value of the image in order to reducing the influence of the gray value change to bit-plane. Usually, we use the following formula to improve the bit-plane, so as to form enhanced bit-plane:

$$a_i' = \begin{cases} a_i \oplus a_{i+1} & ,0 \le i \le 6; \\ a_i & i = 7; \end{cases} \tag{2}$$

For example, when the gray levels are 127 and 128, according to formula (2), it can be deduced that the gray levels of 127 and 128 are 01000000 and 11000000. That means there is only one bit is different between the adjacent gray levels of 127 and 128. As a result, the subtle change of the pixel value has very small influence on the whole plane.

After the image experience LWT changes, the possibility of the "clash" of enhanced bit-plane. Suppose the low pass sub-image of the original image has gone through one level LWT is N×N, then according to the above calculating method, the possibility of "clash" is $(1/2)^{N\times N}$。In reality, the empirical threshold value of judging whether the water print exists or not is less than 1, so the actual possibility of "clash" is bigger than $(1/2)^{N\times N}$， though it is still a very small number.

Watermarking Method

If the original image $f(x,y)$ is a gray image and the watermarking image is a binary image $w(x,y)$, the procedure is as follows:

Embed process:

(1) The scrambled watermark image $w'(x,y)$ is produced by scrambling key.

(2) The original carrier image is decomposed with a one level lifting wavelet transform.

(3) The low pass subimage is divided into 8 enhanced bit-planes.

(4) The 6th order bit-plane $f'(x,y)$ and scrambling image $w'(x,y)$ will be inputted into CNN network, and then the output is marked as $I(x,y)$. $I(x,y)$ is the constructed watermark image. To

improve the security of system, $I(x,y)$ can be encrypted or scrambled. Then the zero-watermarking registration information $I'(x,y)$ is generated.

Detection process:

(1) The constructed watermark $I(x,y)$ is obtained by the key.

(2) The test image is decomposed with a one level lifting wavelet transform.

(3) The low pass subimage of test image is divided into 8 enhanced bit-planes. The 6th order bit-plane is marked as $f''(x,y)$.

(4) Then the $I(x,y)$ and $f''(x,y)$ are inputted into CNN network, and the output is marked as $w_a'(i,j)$. The unscrambled $w_a(i,j)$ watermark image is obtained by the scrambling key used in the embed process.

(5) By means of correlation analysis, the correlation degree of watermark image $w(x,y)$ and abstracted watermark image $w_a(i,j)$ can be computed. The formula is as follows:

$$SIM = \sum_i \sum_j w(x,y) w_a(i,j) / \sum_i \sum_j w^2(x,y) \tag{3}$$

If the value of *SIM* is bigger than the empirical threshold value, the watermarking information exists. If not, the watermarking information does not exist.

Experimental Results

The simulation is implemented by Matlab. A binary image is used as watermark image, and gray image of Cameraman is used as the original image. The original carrier image, original watermark, watermarked image and extracted watermark image are shown as:

(a) (b)

Fig. 1 (a) Original image and watermark (b) Watermarked image and extracted watermark

Simulation results for common image processing operations are shown in Table 1. The values of similarity distribute between 0.9-1, which means this algorithm is robust to common image processing attacks.

Table 1 Results of common attacks

Attacks	SIM
Salt and pepper noise(0.01)	0.93
Gaussian noise (mean 0 and variance of 0.005)	0.92
Median filtering(3 × 3)	0.93
Mean filtering(3 × 3)	0.92
JPEG compression(QF=40)	0.97
Cropping 10%	0.91

Table 2 shows the results of JPEG compression attacks with different quality factors. It shown that this method is robust to JPEG compression.

Table 2 Results of JPEG compression

QF	SIM
100	1.00
80	1.00
60	0.98
40	0.97
20	0.95
10	0.91

Summary

Traditional watermarking algorithm degrades the quality of carrier image, and its application is limited. Since the conflict between imperceptibility and robustness, the embedded strength is also limited. It influences the robustness of watermarking system. The experimental results demonstrate that the proposed algorithm can achieve better visual effect; meanwhile, it is robust to common image processes such as filtering, adding noise, JPEG compression and so on. This algorithm is simple and the realization of software and hardware is convenient.

Research on Simulation of Modern Storage System with Flexsim

Han Qingtian

Naval Aeronautical and Astronautical University, Yantai, China

hbluesky@163.com

Keywords: Storage control; Software simulation; Simulation optimization.

Abstract. Firstly, the store system models was established with Flexsim software. Then the data statistic was taken. Finally, the analysis were carried out with a numerical example. The analysis result shows that emulating is useful for discovering the bottleneck problem of systematic operation, and the simulation is very useful for store system optimization.

Introduction

Automation three-dimensional storehouse is taking high layer three-dimensional goods shelves as major sign, with whole set advanced carry equipment is foundation, is taking advanced computer control technology as major means, come in and go out storehouse handling efficiently using space, time and manpower. Since it have to economize labor force and schoolwork quick accurate , raising take care of efficiency and reduction thing flow out the superiority such as cost, get extensive pay attention , modern thing flows out systematic and traffic transportation, field(port storehouse store up , business match send etc. modern thing flow out system in) get more and more extensive application, become factory thing flow out , flexible production systematic and computer integrated production system in cannot or the important component that are short of. At the same time along with the development of science and technology, especially the development of computer technology, various automation computer systems are replacing the mental work of people partially, and continuously land the creative combination of science and technology with every field, promote the vigorous development of science and technology and go forward , make the function of storehouse since carrying out materials merely store to take care of , development arrives to bear materials with computer system take over to classify to measure to pack , sorting match to send to store the various function such as plate.[1,2]

Zhang Xiaoping studied storage system based on Flexsim simulation[3]. XiaoJiangBo etc. discussed the logistics distribution center based on Flexsim software planning, and gave functional layout of the determination of the size and loading and unloading requirement for distribution center warehouse layout, and the location of the distribution center warehouse building layout were presented[4]. XiaoFeng established simulation model of container terminal handling application using Flexsim, and provided the visual decision support for production managers with loading and unloading process of dynamic simulation [5]. In the paper the model will be established by using the Flexsim software and the analysis will be carried out according to the report.

Store system modeling

According to simulation goal, combine actual condition, established three-dimensional storehouse basic model is as shown in Fig. 1. The Flexsim model is as shown in Fig. 2.

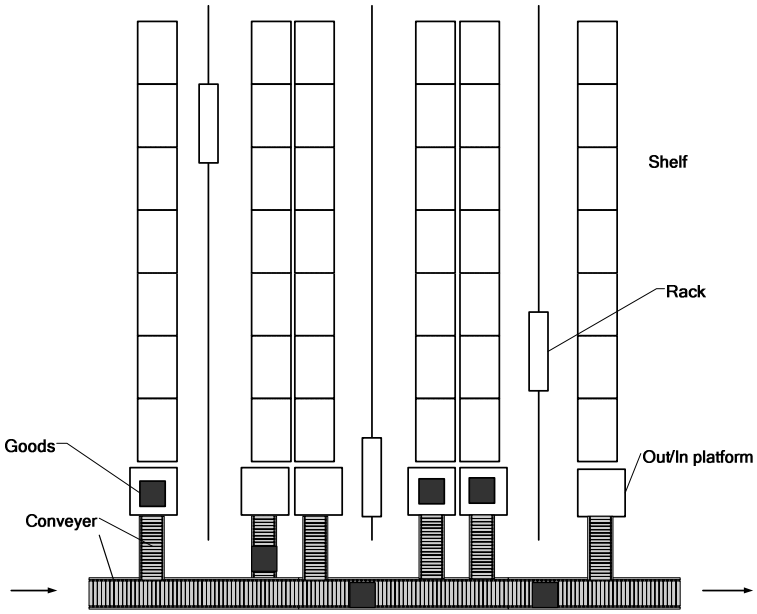

Fig. 1. Store system basic model

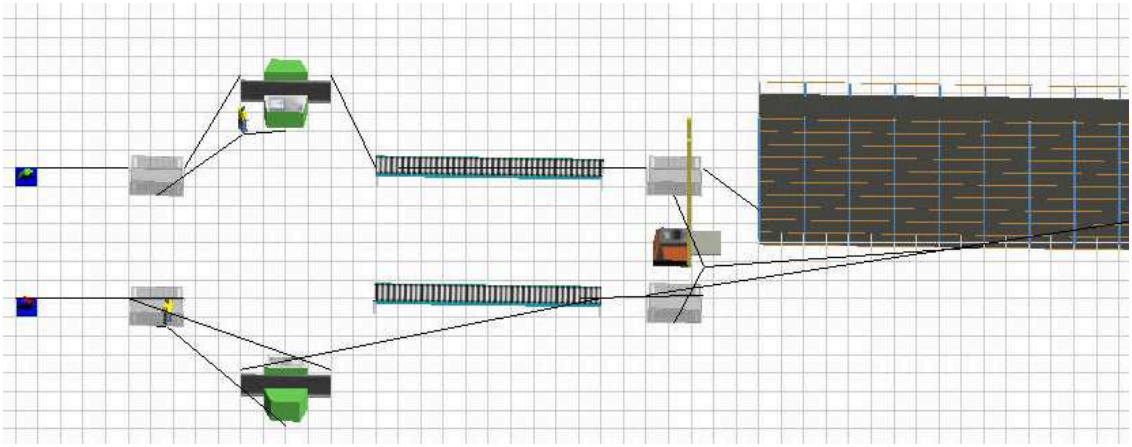

Fig. 2. Store system simulation model using Flexsim

Buffer district adopts conveyer belt make / is put in storage , for instance, will be put in storage free time should be put in storage just to come into stock in buffer district thing, queue up in this formation the most former a goods will enter voluntarily to be put in storage buffer district, the goods of back are entered in proper order forward successively a shelf, queue up continuously to wait. Conveyer deliver goods from outside world arrive to be put in storage platform, and deliver the goods of the platform of delivery of cargo from storage to go out.

Storage system operation process simulation and analysis

Data of work time for into the store is as shown in Table 1.

Table 1. Data of work time for into the store (unit:second)

11.45	12.09	8.9	6.42	10.31	11.89	10.41	11.93	10.49	9.64
10.38	13.45	11.49	11.57	8.88	8.99	10.58	9.73	9.6	9.3
8.6	8.78	9.24	11.78	9.34	10.26	8.97	9.58	10.29	11.83
8.99	7.35	8.76	8.98	9.22	9.78	10.23	11.14	9.7	10.55
9.8	8.74	7.08	10.99	10.3	9.28	11.86	10.45	7.98	9.42

Statistic was taken for the above 40 data, and the frequency and probability were also calculated, and the overall characters of the data can be see. The statistic data result is as shown in table 2.

Table 2. Statistic data analysis result

average	6~7	7~8	8~9	9~10	10~11	11~12	12~13	13~14
frequency	1	3	9	13	13	9	1	1
probability	2%	6%	18%	26%	26%	18%	2%	2%

Usin the software of MATLAB the curve was drawed out, and the parameters were carried out, as shown in Figure 2, Fig. 3.

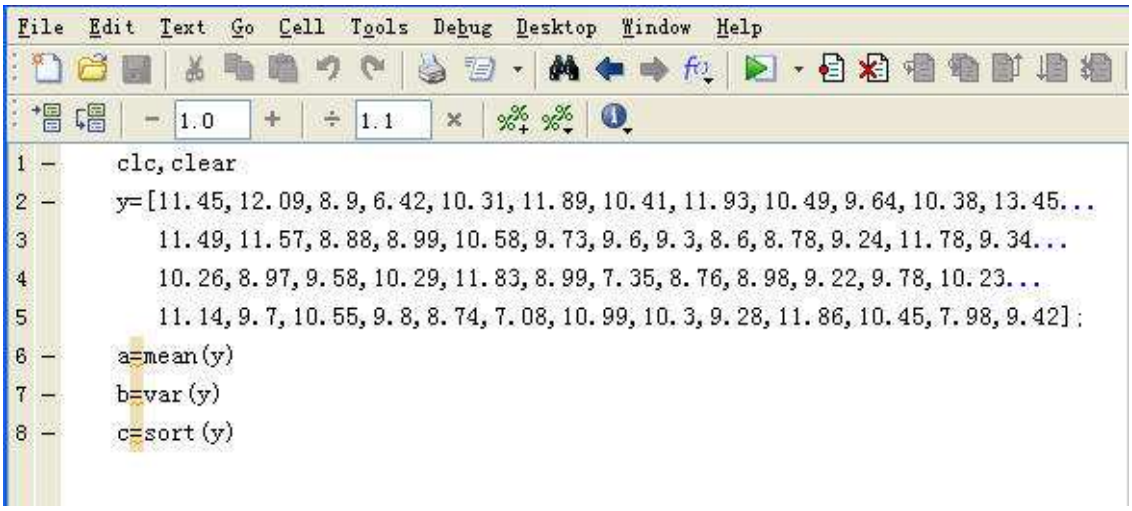

Fig. 3. Source program for the progressing of the data.

In a composite process model, the input curve of the normal distribution, the parameters as follows:

$$\mu = 9.9, \quad \sigma = 1.9 \tag{1}$$

The frequency and probability chart are shown in Fig. 4.

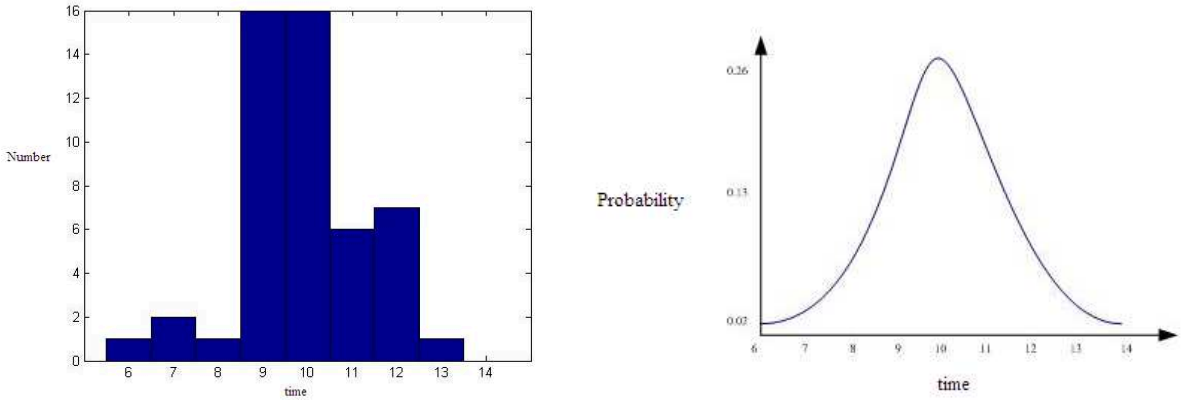

Fig. 4. The frequency and probability chart

Through the simulation of the sorftware flexsim, the export status reporti is as shown in Table 3.

Table 3. Export status reports

	Idle	Processing	Empty	Waiting for transporter	Travel empty	Travel loaded
Queue 1	0.00%	0.00%	0.00%	0.00%	0.00%	0.00%
Conveyer	0.00%	0.00%	49.60%	0.00%	0.00%	0.00%
Queue 2	0.00%	0.00%	71.20%	28.80%	0.00%	0.00%
Piler	46.40%	0.00%	0.00%	0.00%	26.80%	26.80%
Processor	0.00%	100.00%	0.00%	0.00%	0.00%	0.00%

The conveyer pie chart is as shown in Fig. 5.

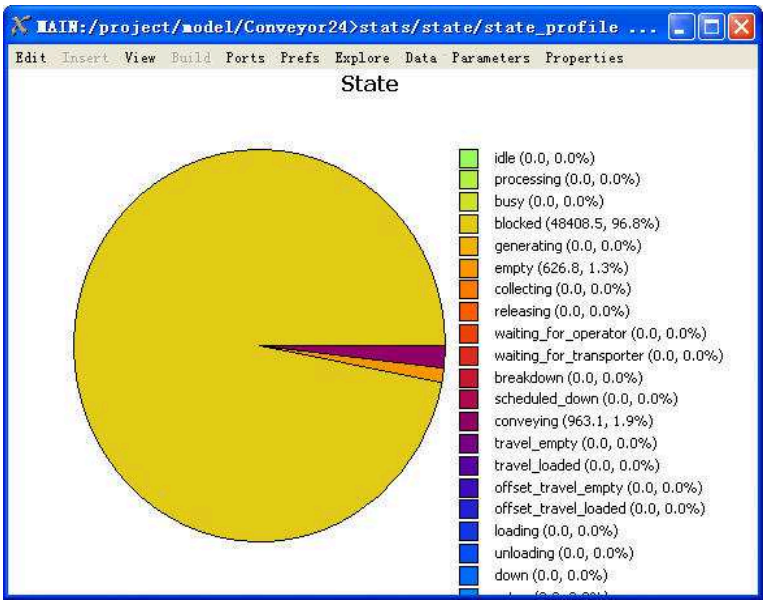

Fig. 5. Conveyer pie chart

From the conveyer pie chart, it can be seen that about 93.2% of the time is the release time, but the 96.8% of the time of the conveyer is in stock. Therefore, since the obstruction of conveyer is caused , delivery of cargo from storage stores district and the obstruction of goods shelves and the low effect.

Conclusions

In the paper, the store system models was established with Flexsim software. The result of the analysis of the example shows that emulating is useful for discovering the bottleneck problem of systematic operation. So the simulation is very useful for store system optimization.

Study on Application of Vendor Managed Inventory Model

Han Qingtian

Naval Aeronautical and Astronautical University, Yantai, China

hbluesky@163.com

Keywords: Material Supply; Vendor Managed Inventory; Inventory Model.

Abstract. Firstly, the inventory models were analyzed, and the symbol and assumptions were given out. Then the models of the distribution centre and supplier were studied. Finally, a numeric example was given out by applying the models. The results show that the models are easily to be carried out in engineering field, and it is useful to control the inventory and raise the store efficiency.

Introduction

The supply chain management is a new concept in the management science. It's greatest characteristic is sharing resource, mutual harmony cooperating, integrate managing betweens upply chain members. So the supply chain cost is reduced greatly. With the increasingly competitive market, more and more enterprises and the introduction of the concept of supply chain management thinking. Inventory management in supply chain management and rapid response to customer demand environment, has an increasingly important position. Traditionally, the various links in the supply chain management of their respective stock, seeking to maximize their own benefit. It is more often the direct consequence of the supply chain to demand more unstable. production eventually increase the overall cost of inventory in the supply chain, affecting the overall optimization of the supply chain operation, weaken its overall competitive edge.[1,2] Based on the idea of supply chain, the model of air material support was developed and its operational mechanism was analyzed and studied by HU Yong etc.[3]

To change this situation, A new supply chain inventory management thinking, Vender Managed Inventory, emerged. In this way, the upstream supply chain downstream enterprises no longer passively according to the orders and additional orders for shipment. but according to their demand for the goods to lower overall grasp of the goods to meet the needs of downstream, It also made its own inventory management and ordering more rational, thus bringing the supply chain to reduce the cost of supply and demand. In this paper, the inventory models of distribution centre and supplier will be studied.[4,5]

Symbol and assumptions

For the vendor management inventory model with shortage not allowed, the symbol and assumption are as follows:

(1) one supplier, many materials distribution centers, and a kind of product;

(2) production speed of supplier is constant;

(3) demand speed that matches to send center is determined;

(4) mend goods can instant realization, it is 0 to match to send central order to expect in advance;

(5) shortage not allowed;

(6) supplier manages the stock that matches to send center, grasps the order information in stock that matches to send center.

And match to send the parameter related to center definition, and parameter definition is as follows:

Parameters for distribution centers are as follows,

n is the number of the distribution centers;

R_i is demand rate of distribution center i, $R_i>0$;
T is order period of distribution center;
Q_{hi} is the maximum stock of distribution center i during time T;
C_{fi} is the order cost of distribution center i;
C_{hi} is the stock cost for the unit product in central in unit time;
TC_i is the total cost of the stock in center in unit time.
Parameters for suppliers are as follows,
P is the production speed of supplier, and $P>\sum_{i=1}^{n} R_i$;
t_{vi} is the time of the supplier satisfies distribution center i during time T;
C_f is regular cost that supplier produces one time;
C_{hp} is the stock cost unit product in supplier in unit time;
TC_{vp} is the total cost in stock in supplier in unit time.

Inventory models of distribution center

Based on the assumptions as above, the changes of the inventory of the distribution centre is as shown in Fig. 1.

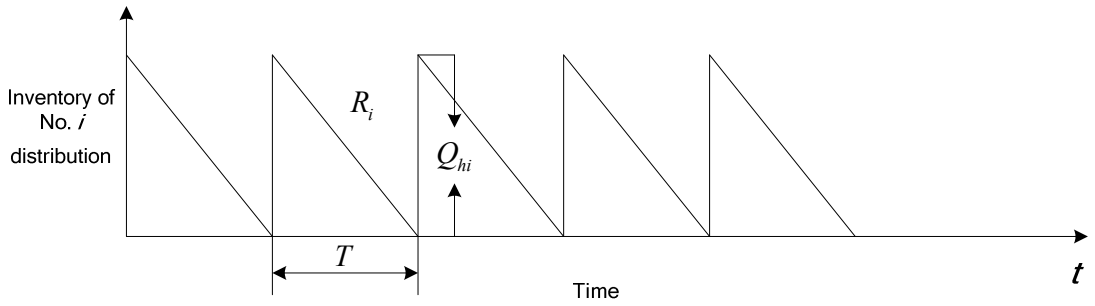

Fig. 1. Changes of the inventory of the distribution centre of NO. i

Here, $I_i(t)$ is supposed as the inventory level of distribution centre i, then

$$\frac{dI_i(t)}{dt}=-R_i, 0\le t\le T, i=1,2,\cdots,n \tag{1}$$

For the boundary condition is as follows,

$$I_i(T)=0, i=1,2,\cdots,n \tag{2}$$

Therefore we can get

$$I_i(t)=R_i(T-t), 0\le t\le T, i=1,2,\cdots,n \tag{3}$$

The cost for store of distribution centre i during periodic time is TC_{hi}

$$TC_{hi}=C_{hi}\int_0^T I_i(t)dt=\frac{C_{hi}R_i}{2}T^2 \tag{4}$$

Therefore, the whole cost for inventory of distribution centre i during periodic time is TC_i:

$$TC_i=\frac{1}{T}(C_{fi}+TC_{hi}) \tag{5}$$

Inventory models of supplier

The change chart of the inventory of the supplier is shown in Fig. 2.

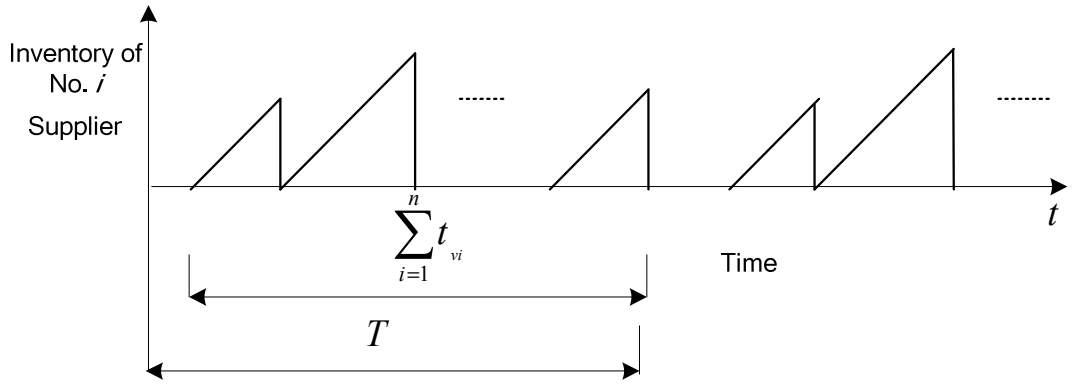

Fig. 2. Changes of the inventory of the supplier

The supplier supply goods to n distribution centers during periodic time T. And let t_{vi} denote the time of supplying goods to distribution centre i. If $I_{vi}(t)$ denotes the inventory level of distribution centre i at time t, then $I_{vi}(t)$ should satisfy the differential equation as follow.

$$\frac{dI_{vi}(t)}{dt} = P \quad 0 \le t \le t_{vi}, i = 1,2,\cdots,n \tag{6}$$

With the boundary condition

$$I_{vi} = 0, i = 1,2,\cdots,n \tag{7}$$

so

$$I_{vi}(t) = Pt, i = 1,2,\cdots,n \tag{8}$$

It is supposed that Q_{hi} denotes the maximum inventory of distribution centre i during the periodic time T,and Q_{si} denotes quantity out of stock of distribution centre i. Then the supplied quantity from supplier to the distribution centre i ant time t_{vi} should satisfied the conditions as follows.

$$I_{vi}(t_{vi}) = Q_{hi}, i = 1,2,\cdots,n \tag{9}$$

$$Q_{hi} = I_i(0) = R_i T \tag{10}$$

Thus we can get

$$t_{vi} = \frac{Q_{hi}}{P} = \frac{R_i}{P} T \tag{11}$$

The store cost of the supplier during time T is TC_{hp}:

$$TC_{hp} = \sum_{i=1}^{n} \left[C_{hp} \int_0^{t_{vi}} I_{vi}(t) dt \right] = \frac{C_{hp} P}{2} \sum_{i=1}^{n} t_{vi}^{\ 2} \tag{12}$$

The whole cost per unit time of the suppliers as follows:

$$TC_{vp} = \frac{1}{T}(C_f + TC_{hp}) = \frac{1}{T}(C_f + \frac{C_{hp} P}{2} \sum_{i=1}^{n} t_{vi}^{\ 2}) \tag{13}$$

The whole inventory cost per unit time in VMI model is TC_{vmi}:

$$TC_{vmi} = \sum_{i=1}^{n} TC_i + TC_{vp}) \tag{14}$$

When ε=0.10, the sensitivity of service level λ according to deference cost is shown in Table 1.

Table 1. Sensitivity analysis of service level

Service level λ	0	0.60	0.70	0.80	0.85	0.90	0.95	1.00
Average inventory cost of distribution centre	100 449	42 769	34 471	27 156	23 979	21 157	18 693	16 565
Average inventory cost of supplier	2 694	2 874	2 904	2 933	2 948	2 963	2 978	2 993
Average inventory cost of VMI	108 982	47 153	38 452	30 905	27 681	24 864	22 454	20 428
ΔTC_{vmi}			-8 701	-7 547	-3 224	-2 817	-2 410	-2 026

Conclusions

In the paper the symbol and assumptions were given out and the models of the distribution centre and supplier were studied. The numeric example show that the models are easily to be carried out in engineering field, and it is useful to control the inventory and raise the store efficiency.

Research on Material Inventory Model and Application

Han Qingtian

Naval Aeronautical and Astronautical University, Yantai, China

hbluesky@163.com

Keywords: Demand Forecast; Model; Double Moving Average.

Abstract. Firstly, the inventory model was analyzed under some assumptions. Secondly, based on the consumption of some rubber product, the demand and inventory models were established. Finally, an actual example was carried out by using the inventory model. The result shows the applicable of the model in engineering.

Introduction

The fundamental objective of studying the logistics system is to reduce the total cost of logistics. But the inventory cost of items is of much more proportion in the total cost of logistics. Therefore, studying the theory and methods of inventory control is very significant for reducing the total cost of logistics. Inventory material takes a considerable part of the total assets in many companies. [1] For one thing, if the materials store is too large, it will occupy too much fund and lead to torpidity of turnover fund. If the materials store is too small, it can't meet the requirement of selling and producing. Also, it is a hot spot of logistics theory research. Therefore, the inventory management plays a major role in a material supplication. [2] Sun Xuelian made further extensive study on the traditional inventory control theory from different aspects [3-5]. This paper the inventory model will be analyzed under some assumptions, and based on the consumption of some rubber product, the demand and inventory model will be established and calculated to illustrate applicable of the model.

Inventory model analysis

Assumptions of the model are as follows.

(1) the cost of out of stock is infinite, that is $C_S = \propto$;

(2) When the stock is zero, the supplement can be presented immediately;

(3) The demand change follows continuing uniform distribution;

(4) For each order, the quantity is a constant, and the order cost is C_D ;

(5) Store cost for per unit is a constant C_P .

During a period time of T , the maximal store quantity is Q , the minimal store quantity is 0, and the demand change follows continuing uniform distribution. So the average store quantity during the period time T is $\frac{1}{2}Q$, and the store cost is $\frac{1}{2}C_P Q$. The cost for once order is C_D , and during time T the average order cost is $\frac{C_D}{T}$. Because the demand is continuing uniform, so $Q = DT$. Therefore, the total cost during time T is as follows.

$$C(T) = \frac{1}{2}C_P Q + \frac{C_D}{T} = \frac{1}{2}C_P DT + \frac{C_D}{T} \tag{1}$$

In order to get the value of T , so let

$$\frac{dc(T)}{dT} = \frac{1}{2}C_P D - \frac{C_D}{T^2} = 0 \tag{2}$$

Therefore

$$T^* = \sqrt{\frac{2C_D}{C_P D}} \tag{3}$$

$$Q^* = DT^* = \sqrt{\frac{2C_D D}{C_P}} \tag{4}$$

$$C(T^*) = \sqrt{2C_D C_P D} \tag{5}$$

The result shows that the C_D is higher, then D more large, and Q is higher. Therefore the store cost C_P is higher, and the Q becomes smaller. The inventory model is shown as Fig. 1.

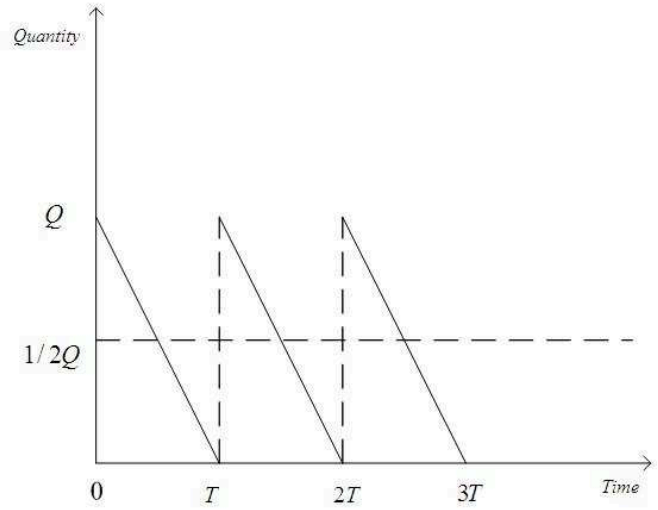

Fig. 1 Inventory model chart

Inventory model applications

Change of the consumption of some rubber product is shown as Fig. 2.

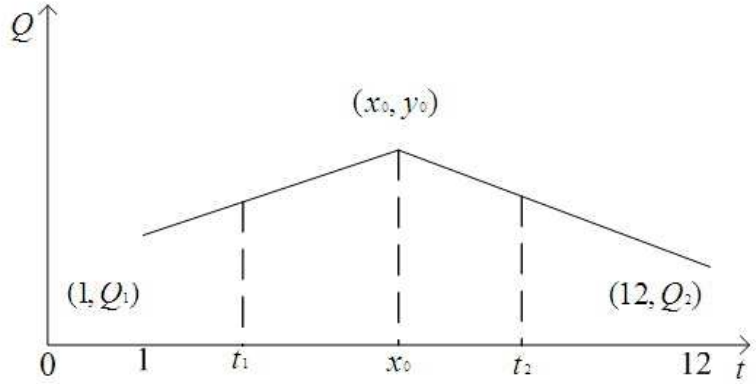

Fig. 2. Change of the consumption of some rubber product

Based on the work intensity, the consumption of some rubber product change as shown in Fig. 2. The change is a function of section.

$$f(t) = \begin{cases} \dfrac{y_0 - Q_1}{x_0 - 1} t (1 \le t \le x_0) \\ \dfrac{Q_2 - y_0}{12 - x_0} t (0 \le t \le 12) \end{cases} \tag{6}$$

According to the consumption of the rubber product, the inventory change can be supposed as shown in Fig. 3.

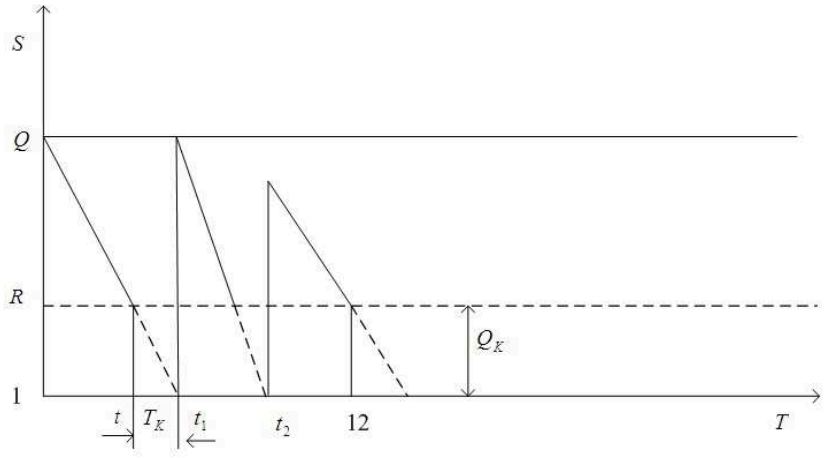

Fig. 3. Inventory change of the rubber product.

At time t_1, the inventory quantity is Q.

$$Q = \int_1^{t_1} f(t)dt \tag{7}$$

Then

$$Q = \int_1^{t_1} (\frac{y_0 - Q_1}{x_0 - 1})tdt = \frac{1}{2}(\frac{y_0 - Q_1}{x_0 - 1})t_1^{\,2} - \frac{1}{2}(\frac{y_0 - Q_1}{x_0 - 1}) \tag{8}$$

Thus,

$$Q = \frac{1}{2}(\frac{y_0 - Q_1}{x_0 - 1})(t_1 + 1)(t_1 - 1) \tag{9}$$

Therefore

$$t_1 = \sqrt{\frac{2Q + y_0 - Q_1}{y_0 - Q_1}} \tag{10}$$

So, the inventory quantity is 0, the supplication is needed. Then the next period begins.

For the safety quantity, the order point is R.

$$T_K = \frac{R}{D} \tag{11}$$

Here D can be calclated by the equation.

$$D = \int_1^{x_0} \frac{y_0 - Q_1}{x_0 - 1_1} tdt + \int_{x_0}^{12} \frac{Q_2 - y_0}{12 - x_0} tdt = \frac{1}{2} x_0^{\,2} (\frac{y_0 - Q_1}{x_0 - 1} - \frac{Q_2 - y_0}{12 - Q_0}) - \frac{1}{2}(\frac{y_0 - Q_1}{x_0 - 1}) + 72(\frac{Q_2 - y_0}{12 - Q_0}) \tag{12}$$

So the order time is as follows.

$$t = t_1 - T_k \tag{13}$$

The economic order quantity Q^* and the total cost C can be determined. At time t_1, the inventory quantity is 0, and the quantity Q_1^* is as follows.

$$Q_1^* = \int_{t_1}^{x_0} \frac{y_0 - Q_1}{x_0 - 1} tdt + \int_{x_0}^{t_2} \frac{Q_2 - y_0}{12 - Q_0} tdt \tag{14}$$

At time t_2, the inventory quantity is 0 again, and the quantity Q_2^* is as follows.

$$Q_2^* = \int_{t_2}^{12} \frac{Q_2 - y_0}{12 - x_0} tdt \tag{15}$$

Therefore, the minimal cost is as follows.

$$C_1 = \frac{1}{2} C_P (P - \frac{y_0 - Q_1}{x_0 - 1}) \frac{Q}{P} (\frac{y_0 - Q_1}{x_0 - 1}) + \frac{C_D}{Q} = \frac{1}{2} C_P (1 - \frac{y_0 - Q_1}{x_0 - 1} p)Q + \frac{C_P}{Q} (\frac{y_0 - Q_1}{x_0 - 1}) \tag{16}$$

$$C_2 = \frac{1}{2}C_P(P - \frac{Q_2 - y_0}{12 - x_0})\frac{Q}{P}(\frac{Q_2 - y_0}{12 - x_0}) + \frac{C_D}{Q} = \frac{1}{2}C_P(1 - \frac{Q_2 - y_0}{12 - x_0}p)Q + \frac{C_P}{Q}(\frac{Q_2 - y_0}{12 - x_0}) \quad (17)$$

According to the model, the function result can be shown in Fig. 4. by using the software tool of MATLAB.

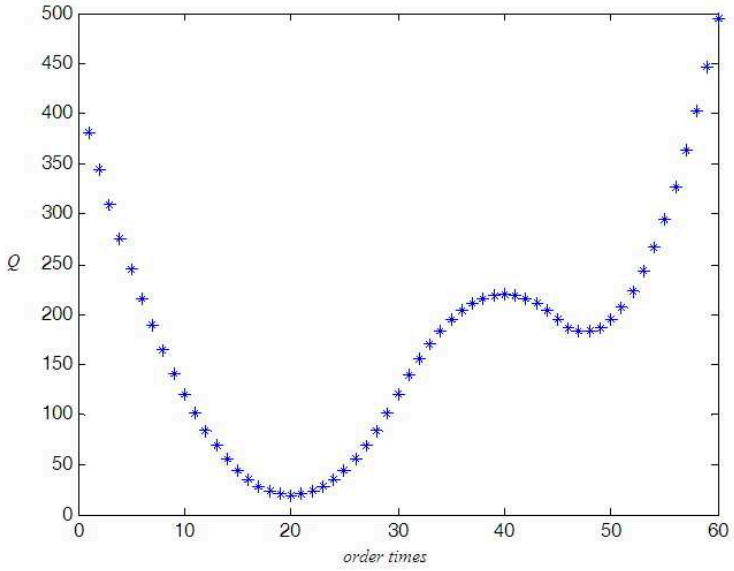

Fig. 4. The cost change according to the order quantity.

From the figure, it can be seen that, when the order quantity is 0, the lost of lack of goods is infinite. And along with the increase of the quantity, the total cost increases. When the quantity meets 20, the cost comes to the minimal. With a concave, the convex increases when the order quantity become larger. The situation accords with the reality of the store management.

Conclusions

In the paper the inventory model was analyzed under some assumptions, and based on the consumption of some rubber product, the demand and inventory models were established and calculated. The result shows the applicable of the model.

Keywords: Enhanced Fuzzy c-means clustering; image segmentation; histogram; moving average smoothing filter; Gauss; peak point detection.

Abstract. Fuzzy c- means (FCM) algorithm is an unsupervised clustering algorithm for image segmentation, and has been widely applied because the segmentation results are consistent with human visual characteristics. Enhanced fuzzy c-means clustering (EnFCM) algorithm is the improved FCM algorithm, which reduces the computational complexity. But, both FCM algorithm and EnFCM algorithm, clustering number still need to be manually determined. This paper, in order to realize the automation degree of algorithm, presents an improved algorithm. It first analyzes the histogram, then automatically determines the clustering number and peak value of each class through use of the peak point detection technology, finally segments image by using EnFCM algorithm. Experiments show that this method is a kind of faster fuzzy clustering algorithm with automatic classification ability for image segmentation.

Introduction

Image segmentation is one of the first and most important tasks in image analysis and computer vision. Fuzzy clustering successfully applied in image segmentation. Among the fuzzy clustering methods, fuzzy c-means (FCM) algorithm is the most popular image segmentation method. However, it still has some disadvantages. A lot of improved algorithm is proposed. A random sampling of FCM algorithm was presented (RSFCM) [1] by Cheng, Xin-bo Gao proposed the FCM algorithm based on weighted (WFCM) [2], Song can Chen proposed KFCM_S [3] algorithm. More recently, Szilagyi [4] proposed EnFCM algorithm, which accelerate the image segmentation process. But, this method still can't overcome disadvantages of manually determining the class number.

In this paper, we automatically determine the clustering number and each clustering centers by using the method of histogram analysis, and the algorithm is initialized with their. Experiments show that this method can make the algorithm reduce the iteration times and the computational overhead on the basis of the effective segmentation.

Histogram Smoothing Method

Gray histogram reflecting the statistical characteristics of image gray distribution is frequently used to study gray distribution of image. For simpler bimodal curve, it is easy to find their peak point location. However, a complex image histogram is generally multi-peak curve, and the complexity of the image itself makes the histogram occur with some peak point features of random disturbance, so it brings difficulties for programs to automatically detect the peak point. Therefore, methods must be taken to eliminate the noise points before the automatic detection of the peak point. This article, through repeat use of moving average method, makes the saw-tooth histogram curve smooth, while maintaining the original histogram peak valley characteristics.

2.1 Moving Average Smoothing Method.

Moving average smoothing method[5], it smooths data by replacing each data point with the average of the neighboring data points defined within the span on the histogram. The conversion relations of smooth processing is $m_i = \frac{1}{2n+1}\sum_{j=i-n}^{i+n} q_j$, where m_i is the smoothed value for the mth data point , n is the number of neighboring data points on either side of m_i, q_j is the value of original histogram probability density, and $2n+1$ is the span. $m_{i+1} = m_i + \frac{1}{2n+1}(q_{i+1+n} - q_{i-n})$ can be available through recursion of m_i.

2.2 Windowed Gaussian Smoothing

Experiments show that the image histogram through repeated use of moving average smoothing method is still some small glitch noise. This paper, in order to completely smooth, makes the histogram smooth by using Windowed Gaussian function [5]. Windowed Gauss discrete function is expressed as:

$$g(i) = \frac{1}{\sqrt{2\pi}w} e^{\frac{-(i-w)^2}{2w}}, (i = 0,1,2,\cdots,2w) . \tag{1}$$

the gray image histogram representation for

$$h(i) = \sum_{x=0}^{m-1}\sum_{y=0}^{n-1} \delta(f(x,y) - i), (i = 0,1,2,\cdots,255) . \tag{2}$$

where w is the window size, $f(x,y)$ is the original image, total pixels of image is $m \times n$, i is Gray level, $\delta(\circ)$ is unit impulse function. The convolution results for

$$r(i) = g(i) * h(i) = \sum_{k=0}^{2w} g(i-k)h(k), i = 0,1,2,3,\cdots,255 + 2w. \tag{3}$$

Automatic Peak Detection Algorithm

In the algorithm of automatic peak detection [6], P_i is the pixel frequency value, compare P_i with the value of its neighborhood P_s, where $P_s = \{P_{i-m},\cdots,P_{i-2},P_{i-1},P_{i+1},P_{i+2},\cdots,P_{i+m}\}$, m is usually an integer between 5 to 15. If the maximum value of P_s is denoted as $P_{s\max}$ and the second largest value of it is $P_{s\max s}$, then the definition of peak function $P(i)$ or valley point function $Q(i)$ for:

$$P(i) = \begin{cases} 1, P_i > P_{s\max} \text{ or } P_i = P_{s\max}, P_i > P_{s\max s} \\ 0, P_i < P_{s\max} \end{cases} . \tag{4}$$

$$Q(i) = \begin{cases} 1, P_i < P_{s\min} \text{ or } P_i = P_{s\min}, P_i < P_{s\min s} \\ 0, P_i > P_{s\min} \end{cases} . \tag{5}$$

Where $0 \le i \le L-1$, L is the maximum gray value of image.

Enhanced Fuzzy C-Means Clustering (EnFCM)

Szilagyi [4], at the base of the study on the FCM algorithm, proposed EnFCM algorithm for gray level images, which reduces the computational complexity. A linearly-weighted sum image g is in advance formed from the original image and its local neighbor average image in terms of

$$g_m = \frac{1}{\alpha+1}\left(x_m + \frac{\alpha}{N_R}\sum_{j\in N_m} x_j\right) . \tag{6}$$

where g_m denotes the gray level value of the mth pixel of the image g, and N_m stands for the set of neighbors(x_j) falling into a window around x_m.The objective function for segmentation of image g is defined as

$$J=\sum_{i=1}^{c}\sum_{l=1}^{q_c}\gamma_l u_{il}^m (g_l - v_i)\,. \quad (7)$$

where q_c denotes the number of gray levels of image g, γ_l is the number of pixels having gray level value equal to l ($l=1,2,\cdots,q_c$). Thus, $\sum_{l=1}^{q_c}\gamma_l = N$ and under the constraint that $\sum_{i=1}^{c}u_{il}=1$ for any l, the J (7) is minimized, using the following equation for calculation of the membership partition matrix and the cluster centers:

$$u_{il}=\frac{(g_l - s_i)^{\frac{2}{m-1}}}{\sum_{j=1}^{c}(g_l - s_i)^{\frac{2}{m-1}}}\,. \quad (8)$$

$$v_i=\frac{\sum_{l=1}^{q_c}\gamma_l u_{il}^m g_l}{\sum_{l=1}^{q_c}\gamma_l u_{il}^m}\,. \quad (9)$$

An Improved Algorithm Based on EnFCM

First of all, this algorithm, through repeating use of moving average method, makes the image histogram smooth. Yet, the smoothed histogram remains more small glitch noise, in order to obtain a better smooth curve, by using windowed Gauss function, makes the histogram curve more smoothing. Then, in the peak detection, set $m=8$, record the number of peaks $Pnum$ and the corresponding gray value of each peak $G=\{g_1,g_2,\cdots g_{Pnum}\}$.

In general, the histogram of the peak and valley reflects the image gray level distribution. Peak is the pixel gray level distribution concentrated area, valley is sparse zone of the pixel distribution. So , can think so, every peak are one class pixel that closely focused around a central value of pixels, class (peak) and class (peak) boundary value exists in the valley. Set EnFCM algorithm class number $c=Pnum$ and the initial clustering centers $V_0=\{v_1,v_2,\cdots,v_c\}=G$.

The detailed steps of the improved algorithm for

Step 1.Make the image histogram, and make it two smooth processing.

Step 2.By using peak detection algorithm, obtain the smoothed histogram peak point number $Pnum$ and the corresponding gray value of each peak G.

Step 3.Set $c=Pnum$, $V_0=G$, and using EnFCM algorithm for image segmentation.

Experimental Results and Analysis

This experiment is to choose a 512 x 512 gray image (Fig.1) for clustering segmentation. First, by using the above smoothing method, makes the selected image histogram smooth, and peak point detection techniques are used to get the clustering number and possible clustering center. Second, randomly choose the clustering centers, segments original image by using EnFCM algorithm, and the result is displayed in Fig.2. Finally, by using the improved algorithm presented in this paper, segments original image, and the result is shown in Fig.3.

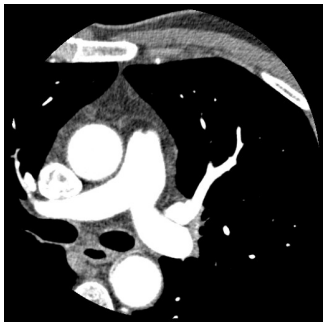

Fig.1. Original image

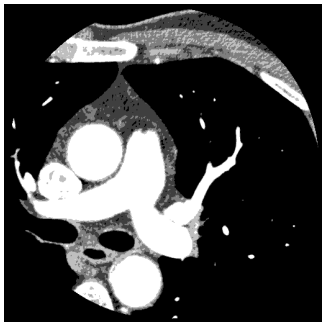

Fig.2. EnFCM result

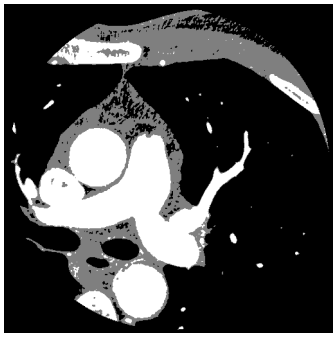

Fig.3. Improved EnFCM result

Segmentation results of Fig.2 show that EnFCM algorithm can obtain more clearly the outline of image, but the border is patchy because of using random initialization of cluster number for image segmentation. Under the condition of invariable parameter in the algorithm, by using the improved algorithm in this paper, segmentation results (Fig.3) for each part of the boundary is clearer, and makes the least number of iterations. On the other hand, under the same parameters, we compare the improved algorithm in this article with EnFCM algorithm of segmentation time, experiments show that the improved algorithm in this article significantly reduces the running time in the similar segmentation results. The reason is that the improved algorithm in this article can provide the number of clusters and the cluster centers by using peak detection technology, therefore, avoid blind iteration that the traditional EnFCM algorithm caused by the initial center selection.

Conclusion

In this paper, we presented an improved algorithm based on EnFCM algorithm. This algorithm, through adopting the peak point detection technology, can automatically determine the cluster number and the peak value of each class, and then improve the automation degree of the algorithm. Experimental results show that the algorithm is suitable for medical image segmentation, and is a kind of faster fuzzy clustering algorithm with automatic classification ability for image segmentation.

Knowledge Representation of Art Patterns Based on the Calculation Mental Image

KUANG ShiRong [1, a]

[1] School of art and design, Jiangxi Science & Technology Normal University, Nanchang 330013,China

[a] KuangShiRong@yeah.net

Key words: knowledge representation; calculation mental image

Abstract. Computational imaginary is a simulation of the human mental image based on the study of cognitive science. Art pattern composition knowledge representation is the basis of the intelligence of computer-aided art pattern design. The paper describes an art pattern composition knowledge representation scheme based on the model of computational imaginary. The scheme includes the deep representation, visual representation and spatial representation, and the operations of these three representations. It further describes the abstract and image information from the perspective of the relation between art pattern layout visual and spatial shape.

1. Introduction

Art design is widely used in the wallpaper, carpet, printing, dyeing and all walks of life. Improving the quality and speed of the graphic design has increasingly become one of the difficulties faced by designers. Computer aided pattern design can accelerate the production speed, but how to make computer simulation of human thinking, quickly and automatically generate the art of novel and attractive design of computer aided pattern design remains an important subject.

2. Calculation mental image theory

2.1 Three parts

At present, there is a controversial about the expression of mental image in the brain. It can be thought of as the image like a hierarchy, an image consists of several mental images. It includes descriptive expression (text or proposition forms), and depicting sexual expression (image). It describes the space between the relationship, and depicts the shape, size, and so on visual information. Psychology study also shows that there is a long-term memory in the brain, descriptively conserves mental images. It is converted into a workspace expression: visual expression and space expression. It can be divided into three parts:

1) deep representation: exist in the form of framework in the long-term memory to realize hierarchy of groups. They are: the name of mental images，AKO, PARTS. AKO indicates the image (a kind of) slot between the properties of the following relationships. PARTS slot is used to decompose the complex mental image and consists of a number of names of mental images and the space. In addition, the framework may also include slots to generate visual expression and space expression.

(2) the visual representation: in the shape of a visual form. Glasgow is represented by a matric composed of a series of basic meta,m each corresponding one expressing the volume of the region, such as light, texture information.

(3) space representation: in the form of multidimensional arrays, symbolic represents the components of space and their relative information. Each component is in the shape of the corresponding part of the position of the element information. For example, the space matrix of a glass of water is shown in figure 1.

glass	water	glass
glass	glass	glass

Figure 1. The space matrix of a glass of water

2.2 The visual expression of composition knowledge

LVR: $\{Tran\ 1.(Subp1)\}$
$SubP = \{Tran\ 1.(Subp1)\}$
Or $SubP = \{(Tran\ 1.(Elem,)\}$
$Elem = \{c(x,y)\}$
$i=1..SubNum$
$J=1..Subp.subNum$
$J=1..SubP.SubNum$
$(x,y) \subset ElemShape$

Efficiency

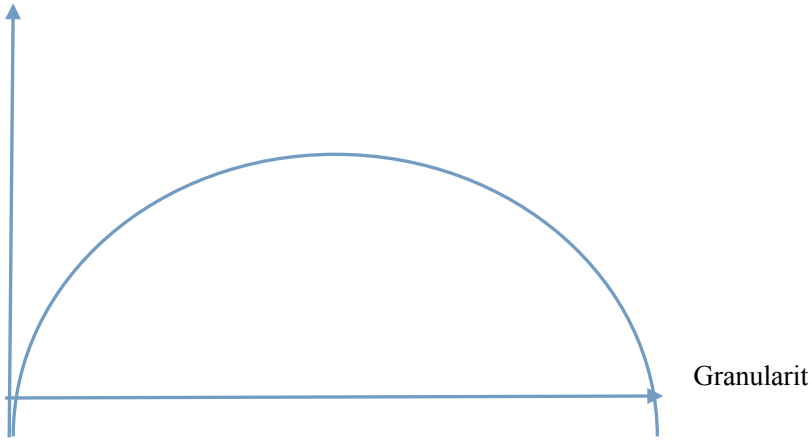

Figure 2. The visual expression LVR

It can be seen that visual expression LVR is produced by SubP of the images

3. The composition knowledge based on calculation mental images

On the composition knowledge expression, we define a series of operations. Expression of the relationship between the transformation and operation can be summed up in figure 3. The SPACE in LRD can reconstruct into operation LVR. LDR in SPACE by retrieve into LSR, can be put on the LSR, delete, move, change the layout of the empty relationship. LSR can be converted in to LDR.

4. The space composition knowledge

Figure 4 is an analysis of the picture. A is a picture whose space matrix is composed of two matrix B and C, B is composed of D and E submatrix while D is composed of two different changes of space matrix.

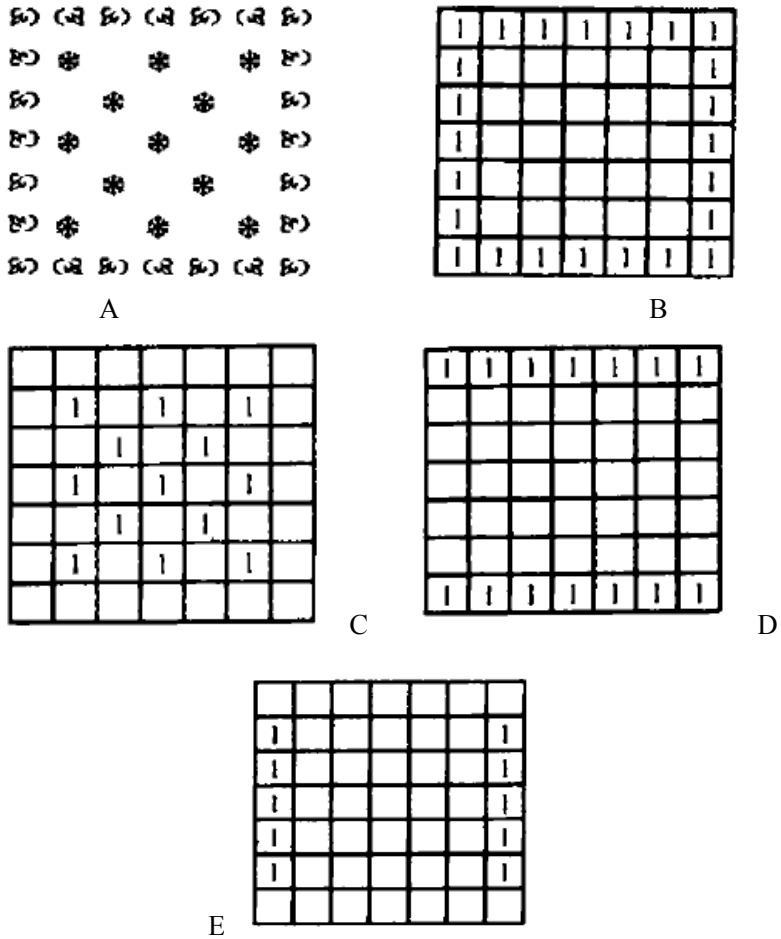

Figure 3. Analysis of the picture

5. Discussion

It can express the incomplete information. For example, in (SUBINFO)，(SUB_ CLOC) , (SUB_TRAN) , (SUB_LOC) (SUB_INDEX) are the chosen items, which means, some information cannot be conveyed very clearly. When (SUBINFO) [(SUB_LOC) (SUB_INDEX) (SUB_LDR)], it shows that this series of layout(up, down, left, right) has determined relationship, but the composition knowledge with exact location of the coordinates of each layout and unknown parameters. That is to say, it instructs the composition knowledge with common points of certain combination.

It explicitly describes the way of combination of layout (rotary, scattered point, straight line), and the corresponding parameters of combinatorial identities such as semantic information. Moreover, the knowledge representation can express incomplete information, indicating a composition of knowledge. Thus it can summarize the knowledge classification, abandon the specific details and extract spatial relationships, combination and other characteristics.

Summary

This paper only expresses deformation and composite structure in the process of the pattern composition without involving aesthetic principles such as balanced effect, golden express. Symbol matrix of space has a lot of spiritual activity, but also have inherent drawbacks. Therefore, the expression of spatial relations is required to expand and optimized. Computer-aided design is the combination of art and computer. This paper is just the preliminary attempt for the image expression in graphic design knowledge. There remains much space for the future study.

[a]yanghai_sdjtu@163.com

Keywords: software cost estimation; COCOMO model; linear regression; estimation error

Abstract. Software cost estimation is the key step to software development management. In order to make COCOMO model applicable to Chinese enterprises, an improved software cost estimation method based on COCOMO model and linear regression was proposed in this paper. Then the replication experiment was taken by using the historical software project data of given enterprises, and then compared experience estimation with the new improved method proposed in this paper about the forecasting accuracy. The results verified that the improved cost estimation method has more practical value to software development.

Introduction

With the rapid development of computer technology, the scale of software is increasing sustainably and software complexity is also getting higher and higher. Cost management of software has become one of the most important parts of software development project. Only by doing this aspect of the cost management so that the quality of software would be guaranteed and the cost of software would be reduced. The software cost estimation is the prerequisite and basis for the cost management. At present, many cost estimation methods have been extensively applied in software industry abroad. But it usually couldn't fulfill the requirement of software industry in China because of the unsuitable of using these cost estimation methods directly.

There have been many cost and schedule estimation models proposed by research literature for the past few decades, such as the estimation models based on regression analysis [1], SLIM model proposed by Putnam 1978, the constructive cost model (COCOMO) proposed by Barry Boehm in 1981 [2], function point analysis (FPA) proposed by David Garmus and David Herron and multi-project model [3].

At present, COCOMO model is one of the most extensively used cost estimation methods. COCOMO model uses a basic regression formula with parameters that are derived from historical project data and current as well as future project characteristics. But the related parameters of COCOMO model should be adjust according to practical situation and statistic data at the beginning of the software development procedure.

In this paper, the parameters of COCOMO model were estimated by using experience estimation and linear regression separately. Finally, the result of linear regression was compared with the one of experience estimation.

Introduction to Relevant Models

COCOMO Model. COCOMO model was first published in Boehm's 1981 book Software Engineering Economics as a model for estimating effort, cost, and schedule for software projects. It drew on a study of 63 projects at TRW Aerospace. The study examined projects ranging in size from 2,000 to 100,000 lines of code, and programming languages ranging from assembly to PL/I [4]. These projects were based on the waterfall model of software development which was prevalent software development process in 1981. References to this model typically call it COCOMO 81.

Basic COCOMO Model. Basic COCOMO model is usually divided into three types: basic COCOMO, intermediate COCOMO and detailed COCOMO. COCOMO model can be constructed by using formula (1)-(3) as follow:

$$E = a \times (KLOC)^b \tag{1}$$

$$DT = c \times E^d \tag{2}$$

$$P = E / DT \tag{3}$$

Where E denotes the effort applied which is measured by person-month, KLOC is the estimated number of delivered lines of source code of software project. DT denotes the development time and P is the people required [5]. The coefficients a, b, c and d are constant given in the following Table 1.

Table 1 Coefficients of COCOMO Model

Software Project	a	b	c	d
Organic	2.4	1.05	2.5	0.38
Embedded	3.6	1.20	2.5	0.32
Semi-Detached	3.0	1.12	2.5	0.35

COCOMO II Model. COCOMO II which was developed in 1995 is the successor of COCOMO 81 and is better suited for estimating modern software development projects. It provides more support for modern software development processes and an updated project database.

COCOMO II model is also divided into three types: the applications composition, early design, and post-architecture models [6]. For example, the construction formula of early design, and post-architecture models is described as formula (4):

$$PM = A \times S^E \times \prod_{i=1}^{n} EM_i \tag{4}$$

Where PM denotes effort, constant A=3.13, S denotes the scale of software, EM_i is the working coefficient and E is calculated by using formula (5):

$$E = B + 0.01 \times \sum_{i=1}^{5} SF_j \tag{5}$$

Where constant B=0.93, SF_j is the characteristic factor.

Linear Regression. Linear regression is an approach for modeling the relationship between a scalar dependent variable y and one or more explanatory variables denoted X. The case of one explanatory variable is called simple linear regression. For more than one explanatory variable, the process is called multiple linear regression.

Given a data set $\{y_i, x_{i1}, ..., x_{ip}\}_{i=1}^{n}$ of n statistical units, a linear regression model assumes that the relationship between the dependent variable y_i and the p-vector of regressors x_i is linear. This relationship is modeled through a disturbance term or error variable ε_i which is an unobserved random variable that adds noise to the linear relationship between the dependent variable and regressors. Thus the model takes the form as follows:

$$y_i = \beta_1 x_{i1} + ... + \beta_p x_{ip} + \varepsilon_i = x_i^T \beta + \varepsilon_i \quad , \ i = 1, ..., n \tag{6}$$

Where T denotes the transpose, so that $x_i^T \beta$ is the inner product between vectors x_i and β. Often these n equations are stacked together and written in vector form as formula (7):

$$y = X\beta + \varepsilon \tag{7}$$

Where

$$y = \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix}, \ x = \begin{pmatrix} x_1^T \\ x_2^T \\ \vdots \\ x_n^T \end{pmatrix} = \begin{pmatrix} x_{11} & \cdots & x_{1p} \\ x_{21} & \cdots & x_{2p} \\ \vdots & \ddots & \vdots \\ x_{n1} & \cdots & x_{np} \end{pmatrix}, \ \beta = \begin{pmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_p \end{pmatrix}, \ \varepsilon = \begin{pmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \vdots \\ \varepsilon_n \end{pmatrix} \tag{8}$$

Improved Software Cost Estimation Method Based on COCOMO Model and Linear Regression (ISCE-CL)

Effort Estimation. In the improved software cost estimation method, effort estimation is calculated by using the formula (1) of COCOMO model mentioned above.

$$E = a \times (KLOC)^b$$

More remarkable, one person-month is consist of 152 effort hours. KLOC is measured by the number of delivered lines (expressed in thousands) of source code.

Schedule Estimation. Schedule means the development time required. Its unit is month. The improved cost estimation method uses the formula (2) to estimate schedule.

$$DT = c \times E^d$$

Linear Regression Model. The parameter correction of COCOMO model is usually taken to confirm the parameters a, b, c and d according to historical data and statistical analysis of software projects [7]. Linear regression is introduced into the improved cost estimation method so as to improve the accuracy of cost estimation.

In the linear regression model of the improved method, the formula (1) is linearized by taking the logarithm on both sides of it. Thus we can gain the formula (9) as follows:

$$\ln(E) = \ln(a) + b \times \ln(KLOC) \tag{9}$$

In order to confirm the value of parameters a and b, the linear regression model is construct by using formula (10) as follows:

$$y_q = \beta_0 + \beta_1 x_{q1} + ... + \beta_k x_{qk} + \varepsilon_q \tag{10}$$

Where $x_{q1},...,x_{qk}$ are the regression variables of the qth observed values. $\beta_1,...,\beta_k$ are response factors. β_0 is the intercept parameter. y_q is the response variable of the qth observed values. ε_q is the random error.

Next, the regression parameters a, b, c and d can be figured out by using least square method (LSM). If the results of least square method are recorded as a^*, b^*, c^*, d^*, the effort estimation based on linear regression is described as formula (11) and the schedule estimation is described as formula (12).

$$E = a^* \times (KLOC)^{b^*} \tag{11}$$

$$DT = c^* \times E^{d^*} \tag{12}$$

Experimental Results

The verification experiments are carried out using the real data of software development projects from Shandong Langchao Cheeloosoft Co.,Ltd.The experimental data are shown in Table 2. For the sake of expressing easily and conveniently, all the names of software projects are omitted.

Table 2 The Experimental Data

Software Project	Equivalent Lines of Code (KLOC)	Number of People(person)	Estimated Schedule(month)	Real Schedule(month)
Project 1	80	23	5	14
Project 2	35	8	4	9
Project 3	20	5	3	5
Project 4	135	12	18	31
Project 5	9	6	3	7
Project 6	25	6	4	7
Project 7	40	9	5	9

By using the least square method proposed in Linear Regression Model section of this paper, $a^* = 2.75$, $a^* = 0.94$, $a^* = 1.72$, and $a^* = -0.13$. Then the effort estimation and schedule estimation were calculated by using the improved cost estimation method ISCE-CL and empirical estimation separately. In order to describe the accuracy of these two methods, we introduced estimated error (Err).

$$Err = | E_1 - E_2 | / E_2 \tag{13}$$

Where E_1 is the real effort and E_2 is the estimated effort. The results are shown in Table 3.

Table 3 Comparison of Results between ISCE-CL and Empirical Estimation

Software Project	ISCE-CL		Empirical Estimation	
	Estimated Effort	Err	Estimated Effort	Err
Project 1	169.14	0.9	115	1.8
Project 2	77.76	0.07	32	1.25
Project 3	45.95	0.46	15	0.67
Project 4	276.60	0.34	216	0.72
Project 5	21.69	0.93	18	1.33
Project 6	56.67	0.26	24	0.75
Project 7	88.16	0.08	45	0.8

The experimental results reflect that the estimated errors of effort estimation from ISCE-CL are universally less than those from empirical estimation. In another word, ISCE-CL is more close to the actual situation and more suitable than empirical estimation.

Conclusion

In this paper, linear regression was introduced into COCOMO model and an improved software cost estimation method based on COCOMO model and linear regression was proposed. Then the verification experiment was taken by using the historical software project data of given enterprises.The experimental results reflect that ISCE-CL proposed by this paper is more close to the actual situation and more suitable than empirical estimation.

Research on Improved Staged Software Cost Estimation Method Based on COCOMO Model

Hai Yang[1, a]

[1]College of Information Science and Electricity Engineering, Shandong Jiaotong University, Jinan, Shandong, China 250023

[a]yanghai_sdjtu@163.com

Keywords: software project; cost estimation; stages divided method; COCOMO model

Abstract. The accuracy of software cost estimation is essential for software development management. By introducing and analyzing the estimation methods of software cost systematically, the paper discussed the necessary of considering the software maintenance stage and estimating the software cost by separating the procedure of software development into several small stages. Then a staged software cost estimation method based on COCOMO model was proposed. The use of the new software cost estimation method proposed by this paper not only contributes to the cost control of software project, but also effectively avoids the bias problem due to using by single cost estimation method so that the accuracy of cost estimation could be improved.

Introduction

With the development of computer and software industry, the scale and complexity of the software are constantly expanding. The software cost gradually became the most expensive part of the entire computer system cost. However, since the sixties of last century, the typical characteristics of the software crisis to budget overruns, quality defects and project delays continue to emerge. Therefore, estimating the software cost becomes particularly important [1].

Summary of Software Cost Estimation

Three Stages of Software Cost Estimation. The software cost estimation is not the expense estimation in the sense of traditional meaning. The main part of capital input of software development is the reward paid for mental labor of the software developers. Usually, what the software cost estimation focuses on are effort and work schedule of software project. After estimating the human cost of software development, the software cost can be estimated according to the situation of development team and other related costs.

Generally, the software cost estimation includes three stages as follows [2]:

Scale Estimation Stage. Scale estimation which is the precondition of effort estimation means to measure the scale of the software. There are two commonly used methods for scale estimation. One is estimating the scale and amount of the problem to be solved, and the other is estimating the scale of solution or complexity of the software. For example, function point is one classic method for the former case and the number of delivered lines of source code is one classic method for the later case.

Effort and Work Schedule Estimation Stage. Effort estimation mainly estimates the human cost which is the main part of the software cost. Meanwhile, work schedule estimation is to forecast the disposable time in each task unit and make the milestone plan. Both effort estimation and work schedule estimation together determine the scale and structure of the software project team.

Estimation Feedback Stage. Estimation feedback stage includes the feedback on the cost estimation method and the feedback on the phased results in practice. It is good useful of adjusting related parameters of cost estimation method so as to improve the accuracy of the estimation results.

Classic Software Cost Estimation Methods. At present, various estimation methods have also born one after another, played a crucial role in their respective field of application, including

estimation method based on model, expert, analogy estimation method, and synthesis technology.Although these methods have been commonly used in software development projects, each one has its disadvantages.

Firstly, all of estimation methods mentioned above regard the software development procedure as a whole object when they estimate cost. So that it is easy to estimate software cost and useful of forecasting the project cost, but it is hard to control project cost because most existing methods can not track and control stage costs in time while the cost of each stage is also necessary for cost estimation. So that it is necessary to improve the estimation methods according to real situation in practice.

Furthermore, some software cost estimation methods only estimate the cost during the development stages. As a result of that, the cost during maintenance which is another important stage of software project is neglected. Facts proved that the effort during maintenance stage accounts for the large proportion of whole software project so that the cost during maintenance stage is much more than those during other stages. That is the reason why most existing cost estimation methods have the bias problems compare to the facts of software development procedure.

According to the analysis above, the improved cost estimation method should not only take the cost during maintenance stage into account but also formulate the cost of each stage of entire software development procedure separately. So that it is much easier for software cost control.

COCOMO Model

The Constructive Cost Model (COCOMO) is an algorithmic software cost estimation model developed by Barry W. Boehm. The model uses a basic regression formula with parameters that are derived from historical project data and current as well as future project characteristics.

Basic COCOMO Model. COCOMO was first published in Boehm's 1981 book Software Engineering Economics [3] as a model for estimating effort, cost, and schedule for software projects. References to this model typically call it COCOMO 81.

COCOMO model is usually divided into three types: basic COCOMO, intermediate COCOMO and detailed COCOMO. Basic COCOMO model can be constructed by using formula (1) as follow:

$$E = a \times S^{b} \tag{1}$$

Where E denotes the effort which is measured by unit person-month, S denotes the scale of software which is measured by the number of delivered lines (expressed in thousands) of source code for software project. Both a and b are constants which are concerned with the type of software project. There are three types of software project shown in Table 1:

Table 1 Three Types of Software Project and Related Coefficients

Software Project	a	b
Organic	2.4	1.05
Embedded	3.6	1.20
Semi-Detached	3.0	1.12

Intermediate COCOMO is an extension of basic COCOMO and its coefficients shown in Table 2. Furthermore, additional 15 effort factors F_i ($i \in [1,15]$) are introduced into intermediate COCOMO.

Table 2 Coefficients of Intermediate COCOMO

Software Project	a	b
Organic	3.2	1.05
Embedded	2.8	1.20
Semi-Detached	3.0	1.12

The formula of intermediate COCOMO is described as follows:

$$E = a \times S^{b} \times EAF \tag{2}$$

Where, $EAF = \prod_{i=1}^{15} F_i$

Detailed COCOMO incorporates all characteristics of the intermediate version with an assessment of the cost driver's impact on each stage of the software engineering process. The formula of detailed COCOMO is the same with that of intermediate version.

COCOMO II Model. COCOMO II which was developed in 1995 is the successor of COCOMO 81 and is better suited for estimating modern software development projects [4]. It provides more support for modern software development processes and an updated project database.

COCOMO II model is also divided into three types: the applications composition, early design, and post-architecture models. For example, the construction formula of early design, and post-architecture models is described as formula (3):

$$PM = A \times S^{E} \times \prod_{i=1}^{n} EM_{i} \tag{3}$$

Where PM denotes effort, constant A=3.13, S denotes the scale of software, EM_i is the working coefficient and E is calculated by using formula (4):

$$E = B + 0.01 \times \sum_{i=1}^{5} SF_{j} \tag{4}$$

Where constant B=0.93, SF_j is the characteristic factor.

Improved Staged Software Cost Estimation Method Based on COCOMO Model

Main Idea of the Improved Method. Generally, the software development procedure is obvious phase-wise which can be divided into five stages: requirements analysis stage, design stage, coding stage, testing stage and maintenance stage [5]. Let C_i , $i \in [1,5]$ denotes the cost of each stage. So the total cost of entire software project C_{total} is calculated by formula (5):

$$C_{total} = \sum_{i=1}^{5} C_{i} \tag{5}$$

By analyzing the practical situation data, we can gain all influence factors of the cost during each stage [6] which are denoted as $(x_{i1}, x_{i2}, ..., x_{in})$, $i \in [1,5]$. Therefore, the cost of each stage C_i can be described as formula (6):

$$C_{i} = \sum_{j=1}^{n} w_{ij} \cdot x_{ij} \tag{6}$$

Where w_{ij} is the weight of influence factor j in stage i. Thus the total cost C_{total} is:

$$C_{total} = \sum_{i=1}^{5} \sum_{j=1}^{n} w_{ij} \cdot x_{xj} \tag{7}$$

Implementation Process of Improved Staged Software Cost Estimation Method Based on COCOMO Model.

Step 1: Calculate the total cost C_C of software project using COCOMO II model.

Step 2: Calculate the total cost C_{stage} of software project again using the staged software cost estimation method proposed by this paper.

Step 3: Consider the weightW_C of COCOMO II model and the weightW_{stage} of the staged cost estimation method according to the practical situation of software project and the historical statistical data. $W_C + W_{stage} = 1$.

Step 4: Calculate the final total software cost C using formula (8):

$$C = W_C \cdot C_C + W_{stage} \cdot C_{stage} \tag{8}$$

Conclusion

The improved cost estimation method proposed in this paper separates the procedure of software development into several small stages and estimate the cost of each stage including the maintenance stage based on COCOMO II model. The use of the improved cost estimation method not only contributes to the cost control of software project, but also effectively avoids the bias problem due to using by single cost estimation method so that the accuracy of cost estimation could be improved.

Keywords: Knowledge fusion; system model; Ontology; Multi-agent

Abstract. Information increase rapidly in recent years which make the effective use of information is not that easy. Knowledge fusion can improve the semantic accuracy and specification of knowledge; it's a useful way to make the mass disordered information integrated and easy to be recognized for users. The paper proposed a knowledge fusion system model based on ontology and multi-agent theory to meet with the user' changing needs at any time.

Introduction

Currently, internet information is filled with our life making a user receives a lot of information from different area every moment with the rapid increase of information. For information users, they want to find out useful information with least time for there are so many information of no use to them which make the finding of useful information time-wasting. Information integration is a useful way to provide useful information to users from the screening and integration of information in a particular field. Ontology theory is an effective knowledge organization way to solve the knowledge acquisition, sharing and reuse issues by providing practical semantic basis and solutions [1]. Multi-agent or intelligent agent can provide users with a transparent view of information according to specific needs ways and means, and can automatically generate information "application" from huge, disordered and dispersed information[2]. In order to meet with users' changing needs at any time, and provide knowledge distributed in heterogeneous sources to users, the paper proposed a model of knowledge fusion system based on ontology and multi-agent.

An Overview of Knowledge Fusion

Knowledge fusion research began at the proposing of knowledge engineering. With the deep development of research on the theme, it becomes an independent field of scientific research.

As defined by Preece at knowledge reuse and fusion transformation project, knowledge fusion is to maximize the development and use of knowledge sources distributed in information system, and to combine knowledge from multiple heterogeneous sources in a highly dynamic way[3].From engineering design perspective, Zou Xiang-jun proposed that knowledge fusion is knowledge engineering applications in the whole process of product development, and it's knowledge embedded in the entire product development process to achieve seamless knowledge fusion[4]. Gou Jin proposed a more comprehensive and universal definition of knowledge fusion that is through the integration of distributed heterogeneous data sources and knowledge sources, knowledge fusion provide services based on knowledge to gain valuable new useful knowledge, and optimize the structure and content of knowledge objects combining the application requirements for knowledge elements transformation, integration and fusion [5].Knowledge fusion research in and out of China mainly focused on the following three aspects:

(1)Model or Framework Building Research of Knowledge Fusion

The KRAFT Architecture for Knowledge Fusion and Transformation proposed KRAFT Knowledge Fusion architecture [3] that is overlap and integration/ transformation architecture of

knowledge by regard constraint as public knowledge exchange form by using a proxy architecture source of knowledge, knowledge fusion entities and users and information transmission communication protocols to achieve the integration of heterogeneous multi-source knowledge and knowledge fusion will be sent to the user. There also have other documents on the theme like a researcher proposed a knowledge fusion model through information fusion DSMT technical knowledge inside and outside the high-tech industry and the use of structural equation modeling to verify the role in promoting the integration of knowledge for knowledge innovation.

(2)Algorithm or Mechanism Research of Knowledge Fusion

As to knowledge fusion, researchers in China mainly focused on the way how to achieve the aim of knowledge fusion and its algorithm and mechanism. Zhou fang proposed a new algorithm based on Bayes, evidence of portfolio theory, theory of three fuzzy information fusion algorithms, and analyzed the characteristic, applicability, usefulness and other aspects [7]. Chen quan introduced the concept of knowledge primers and analyzed the biological characteristics of the four stages of knowledge fusion based on it while using network research community as research background, and proposed knowledge fusion mechanism based on collaborative tagging mechanisms according to different experts[8].

(3)Applied Research in different fields of knowledge fusion

Knowledge Fusion application in China mainly focused on corporate management, product design, subject teaching system construction, and so on. Knowledge Fusion application in out of China even focused on application in military field [9], mobile hospital logistics management to improve decision-making speed through knowledge fusion.

Compared with other countries, research on theory and practice of knowledge fusion in China is still need to be improved. The knowledge fusion research mainly focused on a a specific application areas as research background f, has not yet formed an authoritative general architecture model suitable to multi- field.

Knowledge Fusion Methodology Based on Ontology Theory

In order to provide intelligent support to users or decision makers, knowledge fusion system applied ontology theory to handle user requests. Knowledge Fusion system defines the following ontology types: (1) top ontology, which noted symbols of the system; (2) application ontology, described application areas according to the relevant fields and task; (3) the initial knowledge source ontology, described knowledge sources and top ontology in terms of knowledge source terms; (4) knowledge sources ontology, including terminology correspondence between knowledge source and application ontology; (5) the initial request ontology, described user request and top-level ontology symbols using the user terms (the request input use for user) ; (6) request ontology, including the terminology correspondence between the initial request and the application ontology; (7) domain ontology, described static knowledge of a particular field ; (8) task method ontology, described the problem -solving knowledge in a field. All these ontology are stored in a common ontology database in order to achieve sharing and reuse of ontology.

Top ontology provides a shared public symbols for ontology database. Domain ontology and task ontology form a new kind of knowledge, and this new knowledge provided by experts, acquired from knowledge sources or got from the user's request results. If there is no existing ontology or that related to new knowledge areas/task, you can create new ontology associated with this, or extend the current ontology.

When task method ontology used domain knowledge to describe a task or method, a relationship is necessary to establish domain ontology between the task ontology. According to the selected knowledge representation system, ontology classes need to describe the tasks/ methods of task method ontology first, and then describe the input and output parameters of the task/ methods according to properties of the classes. If the property value of domain ontology is used as a parameter of a task/method, then we need to build the relationship of domain ontology and task/ method ontology, and vice versa.

Parts of the domain ontology and task method ontology composed of an application ontology, which is a conceptual model that described the real-world applications, and its construction is based on a particular area and problems need to be resolved of the areas. If the part of domain ontology related to user request and task method ontology has not yet been integrated into a new application ontology, a connection relationship is necessary to build, that is a relationship between ontology related to users and the new ontology class, otherwise, it need to reuse an existing ontology. Request ontology is composed of initial ontology and application ontology which used to respond user request. The initial request builds the relationship of application ontology and request ontology through the correspondence of their elements. Thus, each initial ontology is associated with a application ontology and a request ontology, as shown in figure 2. It also can be seen from figure 2 that the reuse of application ontology is closely linked to the one-much relationship of application ontology and initial request ontology.

Before handling user requests, it needs to find a suitable knowledge source. From the process of a user request we get multiple knowledge sources, it proved a fact that application ontology and knowledge source ontology have a one-much relationship. And each user has their own request initial request ontology; every knowledge source has their initial knowledge source ontology to describe it, and also has a one-much relationship between initial source knowledge ontology and knowledge source ontology. After acquiring the knowledge associated with the request from the knowledge source, it will be regard this part knowledge and related applications ontology as user requests. The combination relationship of task method ontology and knowledge source ontology is similar to the relationship of task method ontology and request ontology.

Knowledge fusion system is based on a common vocabulary to operate. Application ontology is established based on domain ontology, task ontology and method ontology. Since each user request is running in accordance with the relevant extended request ontology, the application ontology associated with users also regard the extended request ontology as its running basis. During the interaction, the system provides an efficient personalized service through user attributes. Each user request consists of two parts: (1) relationship between request terms and user attributes ;(2) additional constraints defined by users. As to user request, the configuration of an alternate knowledge source network determined when and what kind's knowledge source to use to handle user request effectively. In addition, when using the main ontology of knowledge sources, the implementation of the conversion between system and knowledge source symbols. Thus, a user-oriented, ontology-based knowledge fusion conceptual model is built as shown in figure 2.

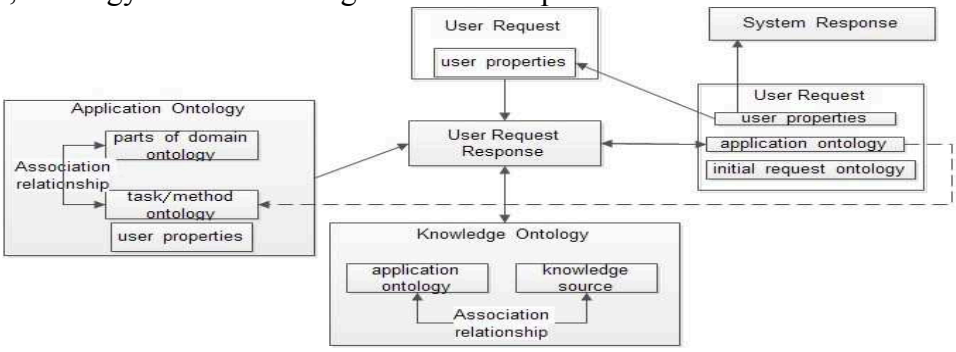

Fig.2 Ontology -based conceptual model of knowledge fusion

Multi- agent Architecture

The knowledge Fusion system uses intelligent software agents to provide the interface between distributed heterogeneous knowledge sources like some other systems. Multi-agent systems provide an effective method for distributed, large-scale, dynamic, open and heterogeneous computing systems and information systems to understand, manage and use. Multi-agent system of this knowledge fusion system is built based on FIPA model for it provides a standard heterogeneous agents and ontology interaction, and standards ontology negotiation protocol. The core technology

agent based FIPA are: packaging agents (with knowledge sources interact), coordinating agent (task execution control), boot agent (an agent with "Blued Pages" directory services) and user agents (with the user interaction). In order to make knowledge fusion system be able to adapt to the changing environment, we provides the following agent: conversion agent (between different vocabulary terms conversion), knowledge fusion agent (knowledge fusion running performance evaluation), configure the proxy (to improve the efficiency of knowledge fusion system), expert's auxiliary agent (to interact with experts) and monitoring agents (knowledge sources confirm).

Each agent of knowledge fusion system includes identification module, function modules and memory modules. Identification module contains a number of parameters, such as a unique identifier, creation time, and so on. The structure of this module depends on the type of the agent (some agent does not need modules). Function module contains a set of intelligent agents need to perform the procedure . Storage module contains some special information, such as knowledge of the agent, the agent's interaction history, temporary results, new knowledge.

Summary

Through the analysis of the operation of the mechanism of knowledge fusion, the paper constructed a general and user information satisfied knowledge fusion ontology conceptual structure based on ontology and intelligent agents, and exampled user requests handling process through emergency logistics common user request. Knowledge fusion regarded solving user problems as the ultimate goal, researched on the use of user attributes and term conversion mechanism, thus to improve the effectiveness of the system to a certain extent. In further studies, we can identify its ability to solve practical problems of the system through knowledge integration evaluation methods to provide a reference for improving the system.

Keywords: Digital Cultural Relics; Classification; Encoding

Abstract. The paper analyzed the status of research on China's digital cultural relics categorizing and encoding which is beginning to develop in China. From the analysis of the characteristics and importance of digital cultural relics categorizing and encoding, the paper proposed a categorizing model and encoding method for digital cultural relics categorizing and encoding.

Introduction

With the rapid development of information technology, the exploration and utilization of digital cultural relics rose to a new level. Especially with the 3D technology, three-dimensional photographic scanning technology and interactive virtual reality technology applied in the digital cultural relics and museums, the process of construction of digital cultural relics and digital museums has been developed quickly since the appliance of those technologies which promoted the comprehensive and sustainable development of cultural undertakings, and promote the smooth progress of heritage preservation, repair, utilization and management. The construction of digital cultural relics and digital museums was begun from the recent years while it began much earlier in the developed countries [1]. Many cultural institutions of China have begun construction of digital museums, cultural relics digitization is becoming a core task of cultural relics of information technology whose importance are increasingly being addressed for the effective protection of cultural resources in the long run. Classification and encoding of digital cultural relics is an important part of cultural relics digitization work [2], thus its important to standardized classification system and encoding rules for digital cultural relics classification and encoding work in order to make digital cultural relics construction more convenient and effective. Therefore, the paper focused on how to carry out the classification and encoding of digital cultural relics.

Connotation and Characteristics Analysis

Connotation Analysis of Classification and Encoding of Digital Cultural Relics . Cultural Relics is a reflection social system, social production and social life of each era which has an important historical, artistic and scientific value. A digital cultural relic, developed with three-dimensional digital technology and other technologies, is digital archiving of cultural relics using 3D modeling technology and other technologies. Digital technology can not only permanent preserve precious cultural relics, but also make it possible for the vast number of cultural relics experts and lovers of joint research and exchange research feelings. So far Longman Grottoes digital cultural relics dimensional digital engineering is the well-known digital cultural relics cases [3]. American emerging management science pioneer Maurice Cook said that: Only when we learn to classification and encoding, simplification and standardization of a work can scientific management be possible to come true [4]. Classification and encoding of digital cultural relics work is based on the combination of cultural features and characteristics of digital technologies to make classification and encoding reasonable and facilitate to search and retrieval which will improve the utilization of cultural resources. Therefore, it's an important part of researches on digital cultural relic classification and encoding that study on scientific and standardization of classification and encoding, and find out the similarity and correlation between digital cultural relics and cultural relics.

Characteristics of Classification and encoding of digital cultural relics. For classification and encoding of cultural relics, its difficult to make a unified classification and encoding criteria for cultural relics as to the kinds and regions of cultural relics are various. China promulgated a number of classification criteria such as the National Heritage Board proposed a unified national heritage classification criteria, Museum Collection Classification, or the cultural relics custody special committee's "Museum Collection category"[5]. But according to the above classification criteria of cultural relics, it may appear cases like a heritage can be attributed in two category, and the above two criteria is a comprehensive classification methods and there is no uniform classification which making the search of cultural relics category difficult [6]. As to criteria on encoding, there are national information encoding standards on it [7], such as People's Republic of China administrative divisions Code standardized administrative code. But to the criteria on encoding of cultural relics, there are no reasonable and uniform encoding modes on it. As the similarity of cultural relics and digital cultural relics, digital cultural relics also faced with the same problems on classification and encoding as cultural relics.

Status and Necessity Analysis of Classification and Encoding of Digital Cultural Relics

With the construction of digital information technology in the application of cultural relics, the pace of cultural relics and museums digitization gradually accelerated. In addition to some of the famous museums began its digital construction, other countries have joined the museums digitization construction community, digital cultural relics began show to the world by electronic devices, hypermedia and so on. China has also started construction of digital cultural relics, such as digital museum building, digital museum studies, and other digital cultural relic researches. Retrieved through National Knowledge Infrastructure database, we got 112 relevant papers by using digital cultural relics as the subject and 888 documents while using digital museum as the retrieval subject, the year limit is from 2000 to 2013. The paper analyzed literature on digital cultural relics and found out that digital cultural relic construction focused on the digital cultural relic environment building rather than building their own connotation and characteristic, and research on digital cultural relics is on its infancy stage, as shown in figure 1.

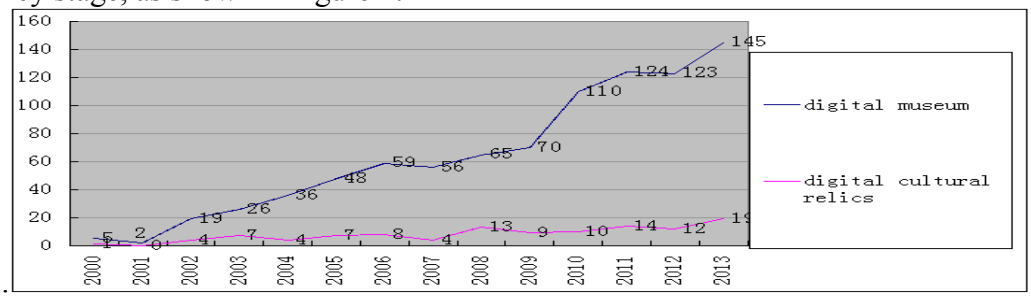

Fig. 1 2000-201. Researches on digital cultural relics and digital museum

Classification and Encoding Model of Digital Cultural Relics

Model of Digital Cultural Relics Classification . The paper proposed classification model of digital cultural relics is shown as table 3. The classification model has three class level and each level has its subclass level. Each class in the model is different with each other and orthogonal to each other, and its subclass has the same characteristics with it. In the paper, we mainly study on the father-class and describe its first subclass, and each class in the model can be extended and be able to adjust or change each class. The first class or main class layer of digital cultural relics classification is based on the properties and attributes of cultural relics which uses era classification methods, named as class A. The second layer is supplementary class named as B, which involved seven subclasses named as D, E, F, G, H, I and J. The third class is property class that is based on the property and characteristics of digitization of digital cultural relics, named as C, and it also involves seven subclasses, shown as in tale 3. Each class shown in table 1 can be subdivided to have its subclass. From the three class layer classification, it can make the digital cultural relic resources more convenient and effective when

query the resources and can make the classification of digital cultural relics more complete and uniform. Here we give a classification example to describe the way to classify digital cultural relic resources. If a classification is ADK1, it means it belongs to an era of class A and has the class property of class D and, K1 is the digital property information of its creator. The model above can keep the cultural relics characteristics of digital cultural relics, and added digitization features of it, thus make the model useful to classify digital cultural relics.

Table1. Classification model description of digital cultural relics

Class	Name	Subclass	Example
Main class A	Times classification	A1，A2,A3.....	Prehistoric,and other historical periods, etc
Supplementary class B	Regional Classification D	D11，D12，D13.....	11Beijing，12Tianjin，according to of administrative area code
	Texture Classification E	E1，E2，E3.....	Stone, jade, etc.
	Function Classification F	F1，F2，F3.....	Ancient architecture, ancient artifacts, etc.
	Property classification G	G1, G2, G3.....	More detailed information refer to common classification of cultural relics
	Value Classification H	H1, H2, H3.....	
	Source Classification I	I1,I2, I3.....	
	Speciation classification J	J1, J2, J3.....	
Digital Property class C	Creator information K	K1,K2.....	Person, Country, etc.
	Collection information L	L1，L2，L3.....	The type of museum, location information, etc.
	Protection level M	M1，M2，M3.....	Special grade, first grade, etc.
	Heritage Theme O	O1, O2, O3.....	The class theme and its theme information
	Related resources P	P1, P2, P3.....	Related resources of cultural relics
	Subsidiary information Q	Q1, Q2, Q3.....	Subsidiary information
	Others N	To be extended	To be extended

Design model of digital cultural relics encoding. The aim of digital cultural relics encoding is to achieving effective sharing of digital cultural relic information. Therefore, unified encoding method not only benefit using computer to cope with digital cultural relics information[8], but benefit the correspondence with digital cultural relics classification categories to reflect the digital cultural relics and other information. The design of digital cultural relics encoding model should follow information encoding standards. At present, China's information encoding standards include “administrative divisions code of People's Republic of China”, “national industry classification code”, and so on. The common information encoding types are no meaningful code and meaning code. Disorder code and ordered code belong to no meaning code while layer code, abbreviations code and combination codes are meaningful code. The paper selected layer code as the code method for layer code often used in linear classification as each class can be coded with sequential code which is appropriate for the pape. The digital cultural relics encoding model is shown in table 4. In layer code, its location means its layer and the one in the left is beyond the level in right. As digital cultural relics have three class, the code model also has three layer, that is layer 1,2,3, each layer begin with 1,2,3 (namely, encoding like 100,200,300, etc.), and the subclass was encoded like 101,201,301,etc while 101 means its the code of main class and its first subclass, 201 means its the code of Supplementary class and its first class,

301 means its the code of main class and its first subclass, shown as table 2. From the encoding model each code has its clear meaning and it's for computer to recognize.

Table2. Description of encoding model

Classification		Code display	Code number and list
Main class A	A	1(00)	101,102,103...
Supplementary class B	D	201(00)	20101，20102...
	E	202(00)	20201，20202...
	F	203(00)	20301，20302...
	.....	.....	.....
Digital Property class C	K	301(00)	30101，30102...
	L	302(00)	30201，30202....
	M	303(00)	30301，30302...
	.....	.....	.....

Summary

The construction of digital cultural relics is later than the developed countries, and the study of digital cultural relics is still in its infancy stage, the study of classification and encoding of digital cultural relics is less involved compared with other research topics. As classification and encoding of digital cultural relics will contribute to the effective inquiries and utilization of cultural resources, the study on it has an important significance. Through the study of digital cultural relics classification and encoding, the paper discussed the status of classification and encoding of digital cultural relics in China, analyzed its connotation and properties, and proposed the basic model of a classification and encoding of digital cultural relics.

Keywords: cloud computing, digital forensics, OCL, FODA

Abstract. Cloud Computing is gaining acceptance and increasing in popularity. However, digital forensics within Cloud becomes difficult. This paper proposes an extensible semantic model using OCL (Object Constraint Language) for cloud digital forensics data. We give a brief introduction to Trusted Digital Forensics, and then detail the modeling process using OCL and FODA (Feature Oriented Domain Analysis). Therefore, a feature tree can be built with semantic logical relation in order to get the overall semantic description of features in the forensic domain of digital data.

Introduction

As long as people are involved there will be crime. The need for Digital Forensics exists because some of these crimes or other incident is taking place on computer system. Cloud forensics [1] is Digital Forensics applied on Cloud Computing. Cloud Forensics is a subset of Computer Forensics as a cloud runs on a network and consists of network equipment. Cloud Forensics also entails Computer Forensics as a cloud consists of nodes that are computers. This means that Cloud Forensics ties Computer and Network Forensics together. The introduction of clouds complicated the digital forensic process [2]. There is a belief that a digital investigation a cloud can be difficult to do. The need to have formal and proven methods to conduct a digital investigation on a cloud became apparent.

So this paper proposes an extensible semantic model for cloud digital forensics data. Its structure is organized as follows: firstly, we give a brief introduction to Trusted Digital Forensics. Secondly, we discuss the details of modeling cloud forensics using OCL [3] and conclude the paper finally.

The Concept of Trusted Digital Forensics

The trusted computing is the action of trusted components, and its operation or process is predictable under any operating condition [4]. It can as well resist the destruction from application software, virus, and physical interference. The ultimate purpose is to ensure the information integrality of the entity. In the process of digital forensics, we can establish a trusted evidence theory system referring to the thought of trust and trusted computing. The digital forensics can be divided into two aspects: one is the trust of static property, namely to ensure that the static semantic features on process of trusted discovery and trusted fixation is trusted; the other one is the trust of dynamic behavior, namely to make the process or trusted behavior of digital data transformed into evidence trusted from the following three aspects: trusted extraction, trusted analysis, and trusted expression. This paper mainly focuses on the static property.

The Feature Model of Cloud Digital Data

Feature is perception of the system from certain perspectives, which can be regarded as an information collection of describing domain models [5].

FODA (Feature-Oriented Domain Analysis) [5] modeling is related to two conceptions: abstract and refining. Abstract describes the common requirement in the field of application system, namely, abstracts the generality. Its main purpose is to acquire the field model. Refining can be used to develop the specific applications. When modeling in the process of FODA field, and by decomposing and merging the abstracted features in the field of application system, a feature tree of semantic logical relation is built. Then the overall feature semantic description of the forensic domain of digital data is obtained, and DFM (Domain Feature Model) [6] is modeling.

Definition 1. FM (**Feature Model**) can be represented as a 3-tuple <*feature*, *relation*, *constraint*>, where *feature* is the feature collection, whose elements are the feature items in the feature tree; *relation* is the logical relation collection of feature; *constraint* is the constraint collection of features and their relations among them.

Definition 2. CFDFM (**Cloud Forensics Data Feature Model**). CFDFM is a kind of construction model of feature models, it should satisfy the following constraints:

context *CFDFM* inv :

self.stereotype = *FM* and

self→*ownedElement*→*forAll* (*p* | *p*. *oclIsKindOf* (*Feature*) or *p.oclIsKindOf* (*Relation*) or *p.oclIsKindOf* (*Constraint*)) and *self.Feature*→*includes* (*name*) and *self.Feature*→*includes* (*type*) and *self.Feature*→*includes* (*size*) and *self.Feature*→*includes* (*location*) and *self.Feature*→*includes* (*createTime*) and *self.Feature*→*includes* (*visitTime*) and *self.Feature*→*includes* (*modifyTime*) and *self.Feature*→*includes* (*content*)

where, *feature*, *relation*, and *constraint* is the elements of CFDFM; *name*, *type*, *size*, *location*, and *content* is the name of digital data (the identification of digital data), *type* (such as txt, jpg, pdf, rmvb, etc), *size*, *path*, and *content*; *createTime*, *visitTime*, *modifyTime* is the creating time, the last access time, and the last modifying time of the digital data.

In the CFDFM, the element *Constraint* is the feature-constraint description of the components. It includes the constraint of inherent features, as well as the constraint of extended features. According to the different relations between kinds of features, we can divide them into four classes: self-constraint, "father-son" feature relation constraint, dominant relation constraint, and recessive relation constraint.

A) Self-constraint

Definition 3. (**Self-constraint**). Self-constraint is the rule that digital data features should meet for some constraint of their own properties.

In the CFDFM inherent feature, for example, name has the typical feature of the constraint. Its uniqueness should satisfy the constraint as follows:

context *name* inv :

self.oclIsKindOf (*Feature*) and *self.allInstances.value*→*isUnique* (*n* | *n*)--*self.allInstances*→*forAll* (f_1, f_2 | f_1<>f_2 implies f_1.*value* <> f_2.*value*)

B) "Father-son" Feature Relation Constraint

Definition 4. (**Father feature and son feature**). Assume that there are two features f_a and f_b. If f_a is the refinement of f_b's direct semantic level, we can conclude that f_a is f_b's son feature, and f_b is f_a's father feature. In the digital data feature tree, "father-son" feature can be divided into *mandatory* constraint, *optional* constraint, and *multiplicity* constraint.

Definition 5. (**Mandatory**) If a son feature *cFeature* and father feature *pFeature* satisfy the constraint:

context *cFeature*, *pFeature* inv *mandatory* :

pFeature.subFeature→*notEmpty*( ) implies *pFeature.subFeatures*→*includes*(*cFeature*)

We can say that *cFeature* is more mandatory, compared to *pFeature*, which can be denoted as *mandatory*(*pFeature*, *cFeature*).

Definition 6. (**Optional**). If a son feature *cFeature* and father feature *pFeature* satisfy the constraint:

context *cFeature* ,*pFeature* inv *option*:

pFeature.subFeatures→notEmpty () implies (*pFeature.subFeatures→includes*(*cFeature*) or *pFeature.subFeatures→excludes*(*cFeature*))

We can say that *cFeature* is more optional, compared to *pFeature*, , which can be denoted as *option*(*pFeature*, *cFeature*).

Definition 7. (**Multiplicities**). Multiplicities constraint is the constraint of repeat numbers that *father* to *son*.

UML2.0 rules show four kinds of repeat numbers, as Table 1 shows.

Table 1 Multiplicity

Symbol	Lower Bounds	Upper Bounds	Explanation
0..1	0	1	At most one instance of the sub-feature
1	1	1	Only one instance of the sub-feature
0..*	0	Infinity	Arbitrary
1..*	1	Infinity	At least one instance of the sub-feature

In CFDFM, the multiplicity between "father-son" features is a positive integer or interval. As a result, we can expand UML repeat number so as to support more repeat numbers with more form. As the repeat numbers are nonnegative integers, repeat numbers can be divided into 3 classes: N, N_1 .. N_2, and N_3 ..*,($N > 0$, $N_2 > N_1 = 0$, $N_3 = 0$). The multiplicity constraint between "father-son" features can be described by OCL below:

context *cFeature*, *pFeature* inv:

pFeature.subFeatures→includes(*cFeature*) and *cFeature.allInstances→size*() = N

context *cFeature* ,*pFeature* inv:

pFeature.subFeatures→includes(*cFeature*) and *cFeature.allInstances→size*() >= N_1 and *cFeature.allInstances→size*() =< N_2

context *cFeature* ,*pFeature* inv:

pFeature.subFeatures→includes(*cFeature*) and *cFeature.allInstances→size*() >= N_3

C) Dominant Relation Constraint

Dominant relation constraint means that two features between non-"father-son" relationship exists somehow direct relation: alternative, depends, or excludes.

Definition 8. (**Alternative**). If two features *feature-a* and *feature-b* satisfy the following constraint:

context *feature-a* ,*feature-b* inv alternative :

CFDFM.Feature→excludes(*feature-a*) implies *CFDFM.Feature→includes*(*feature-b*) and *CFDFM.Feature→excludes*(*feature-b*) implies *CFDFM.Feature→includes* (*feature-a*)

We can conclude that *feature-a* and *feature-b* are alternative, which can be denoted as *alternative*(*feature-a*, *feature-b*).

Alternative makes it a rule that at least one feature must be chosen from the two features *feature-a* and *feature-b*, which not only reflects the indispensable but multiple parts in the field application, but also represents the different process and expression of the same feature in different applications.

Definition 9. (**Depends**). If two features *feature-a* and *feature-b* meet the constraint:

Context *feature-a*, *feature-b* inv *depends* :

CFDFM.Feature→includes(*feature-a*) implies *CFDFM.Feature→includes*(*feature-b*)

We can conclude that *feature-a* depends on *feature-b*, which can be denoted as *depends*(*feature-a*, *feature-b*).

In CFDFM, *depends* always exist between feature and element feature(description of feature).

Definition 10. (**Excludes**). If two features *feature-a* and *feature-b* meet the constraint:
context *feature-a*, *feature-b* inv *excludes* :
CFDFM.Feature→includes (*feature-a*) implies *CFDFM.Feature→excludes*(*feature-b*) and
CFDFM.Feature→includes (*feature-b*) implies *CFDFM.Feature→excludes*(*feature-a*)

We can conclude that *feature-a* and *feature-b* are mutually exclusive, which can be denoted as *excludes* (*feature-a*, *feature-b*).

Exclude constraint shows that two features are mutually exclusive and cannot exist in the same field application.

D) Recessive Relation Constraint

Recessive relation constraint is a kind of constraint that exists among features caused by the definition of digital data, the environment of digital data, and the internal relationship between essential features. For an example, in CFDFM, *createTime* is smaller than *visitTime* and *modifyTime*, namely:

Context *createTime*,*visitTime*,*modifyTime* inv:
visitTime >= *createTime* and *modifyTime* >= *createTime*

We can conclude the four classes of constraint between digital data features based on analysis of feature field method on combining digital data semantic features. These constraints are not only suitable for describing the relation of inherent features in CFDFM, but also suitable for describing the relation of extended features in CFDFM. Next, horizontal and vertical analysis can be launched on practical cases through CFDFM, the feature tree can be built, and the dependency and relevancy between features can be represented by the related operations using OCL.

Summary

This paper uses FODA to build a static semantic feature model for cloud forensics digital data, and formally describe all kinds of features of digital data in OCL. It classifies those features through “collection” and “collection operation”, and describes the relationship and dependency between them. Our future work will focus on discussing the formalized verification method of trusted discovery and trusted fixation.

Keywords: Loss of customers; Logistic regression; Prediction model; Model validation

Abstract. At present, the competition is increasingly fierce between the securities company, whether can effectively prevent the loss of users, reducing loss rate is a difficult problem at present each securities company urgently needs to solve. The model based on the principle of data mining, proposes a prediction method based on Logistic regression algorithm. Prediction model is built based on Logistic regression algorithm and the validity and accuracy of the model is verified by experiment, provides a new method and thinking for the securities company customer churn prediction.

Introduction

With the continuous development of the securities market in China, there has been a shift in securities companies' business operations to a more centralized and tightly-controlled model. As a result of the increasingly fierce competitions and the emphasis on value-added services, customer loyalty has become a common problem faced by the securities industry. Therefore, a customer-oriented service model and more targeted marketing strategies are believed to be the key to building and retaining the competitiveness of the securities companies.

Companies that have no clearly-defined contractual agreements with their clients quite often find themselves in constant risks of loosing customers and profits. Therefore, how to find the prospective customers and successfully retain them has become the focus of many securities companies in their short-term and long-term business strategies. Trading behaviors over a period of time, causes for customer loss and other factors are analyzed to determine the appropriate strategy or means to develop and maintain customers and remain profitable.

Using the Logistic regression analysis method, this research has established an effective customer churn prediction model by analyzing historical transaction data up to six months. The aim of this research is to develop a tool that the securities companies can use to analyze trends and forecast customers that are in a higher risk of losing so that timely measures can be deployed to retain customers and ensure they stay loyal and increase profitability.

Logistic regression prediction principle

Logistic regression is an important method for the analysis of categorical data statistics. Beginning in 1980s, it has been used for event prediction, the study of non-linear relationships between the probability of an event and the influencing factors of the event, and the identification of risk factors of the incident [1].Logistic regression analysis considerably overcomes the shortcomings of the linear hypothesis method, by reducing the restrictions of overall distribution. There are no assumptions about the distribution of the independent variables,and the argument can be continuous variables, discrete variables and dummy variables. Logistic regression determines the strain response based on the model fitting and the model approach between the variables and the dependent variable. Its main purpose is to classify, and estimates the probability of events.

For dichotomous questions, assuming the individual options $y=1$ indicates that the client properly and $y=0$ indicates that the customers churn and that $x=(x_1,x_2,\cdots,x_k)$ indicates that the associated descriptive variables can be obtained in the database, and then the established mathematical expressions for the Logistic regression model is:

$$\text{logit}\left(p(y=1)\right)=\ln\left(\frac{p(y=1)}{1-p(y=1)}\right)=\beta_0+\beta_1x_1+\cdots+\beta_kx_k \quad (1)$$
$$=\beta_0+\sum_{i=1}^{k}\beta_ix_i$$

$$P\left(y=1\mid x\right)=\frac{\exp\{\beta_0+\sum_{i=1}^{k}\beta_ix_i\}}{1+\exp\{\beta_0+\sum_{i=1}^{k}\beta_ix_i\}} \quad (2)$$

$$P\left(y=0\mid x\right)=\frac{1}{1+\exp\{\beta_0+\sum_{i=1}^{k}\beta_ix_i\}}$$

Among them $\beta_i\left(i=1,\cdots,k\right)$ is coefficient of each variable after logistic regression,Its meaning is: when x_i change an unit of measurement each caused by the change in the natural logarithm; β_0 behalf Intercept. Formula（2） represents the probability of loosing certain customers. Among them $P\left(y=1\mid x\right)$ expresses the probability of a normal customer, $P\left(y=0\mid x\right)$) indicates the probability of churn.

Table 1 Users monthly data table

Month	Total commission	Trading clients	Average commission	Quality customers	Premium customers of commission
200805	4275736.27	12033	355.33	2398	1308278.04（30.60%）
200807	16469120	40214	409.54	7859	6473401.56（39.06%）
200808	8836430.38	33689	262.29	6357	4206377.16（47.60%）

LJMC_ZSZ_4M_BL	Cumulative proportion of the total market capitalization and sold nearly 4 months	0.460734314
LJMCYJ_ZSZ_4M_BL	The cumulative proportion of the total market value and selling commission nearly four months	0.445815741
LJMC_ZSZ_2M_BL	Cumulative proportion of the total market capitalization and sold nearly 2 months	0.443599602

Logistic regressions customer churn prediction

Data preprocessing

In the data preprocessing, we will group data into two categories: customer information data and customer transactions data.

Customer information data. Customer information data refers to the customer information, such as the customer's gender, age, marital status, educational status, occupation and capital scale. Due to historical reasons, our customers' electronic documentation is incomplete, missing most of the data; only the size of the customer's financial data can be exported via the customer's transaction data. Therefore the customer information data model structure we use includes only the size of their capitals.

Customer transaction behavior data. Customer transaction behavior data includes: Changes in the position data of customers, the number of monthly transactions, turnovers, monthly commission fees, etc. Users with the monthly data are shown in Table 1.

Logistic regression model structure

Data Preparation. The prediction model established in this article uses data from a securities company over a year, in the four months from September to December statistical data was collected. The time period used to predict customer behaviors are likely to trigger future marketing response. January to March next year is forecast to month, using the model created to predict customer marketing response.

Define variables and variables derived. In order to ensure the accuracy of the model prediction, we use 91 factors securities company's customer data to make predictions. These 91 factors include asset data, transaction data, basic customer information, customer service and product information such as customer subscriptions, five aspects. Through the chain, the result was worse than the method by the 91 factors derived 275 variables.

Data preprocessing and correlation analysis. According to this study, the correlation of explanatory variables and target variable, select the 150 most relevant variables.

Logistic regression modeling

Screening AR variables on the basis of Table 2, we do logistic regression to 150 variables use SAS. Getting lost probability between the univariate regression and univariate of each customer. After the loss probability Sort, Getting the value m% is the proportion of the cumulative loss of customers top n% (n=1…100). We obtain a curve between m% and n% (as shown in Figure 1), then obtain the AR values for each variable. Choose the high value of the variable AR from them. Also, delete the experience value of less than 0.73 of the variable AR. After this step, we obtain the 45 variables.

Select the maximum likelihood estimates of large and significant variables use Logistic regression forward stepwise regression method, stepwise regression, definition the loss of value of the target variable as 0, then

$$P_{\text{outflow}}=1\text{-P}=\frac{1}{1+\exp\{\beta_0+\sum_{i=1}^{k}\beta_i x_i\}}$$

When the regression coefficient β_i is positive, variable x is the larger, P_{outflow} is smaller; Contrary, When β_i is negative,variable x is smaller,P_{outflow} is larger. Therefore, the size of the sign and the loss probability of regression coefficients showed a negative relationship. After this step, we obtained 21 variables.

Empirical Analysis

Model evaluation phase is to test the model has been established. Model checking is the important step for the data mining, there are two principles in determining the goals and data mining preparation stage, the first is, the prediction model can be assessed and must be realized, and the second is, the resulting model can be used in a real-world environment.

Select the observation period and object. Before proceeding with data collection, we define the time interval churn models examined below. On observing the object, we screened for individual customers conditions include: Customer average monthly assets between the 1,000 yuan to 10 million yuan in the observation period; Opening time from the observation period over four months; There are transactions within the observation period 4 months.

Determine the variables and regression coefficients. Performed logistic regression calculation again for the 21 variables, confirm the regression coefficients and constant coefficient of these variables. The constant coefficient of the churn model is 0.2708204106.

Estimation Results. KS (Kolmogorov-Smirnov) is mainly used to validate the ability of the model, that distinguish the lost objects, verify the ability of the model accurately distinguish normal customers and the churn. This model predicts KS value is 44.678, as shown in Table 3, indicating that the model has a strong ability to identify for the churn, so this model prediction is credible.

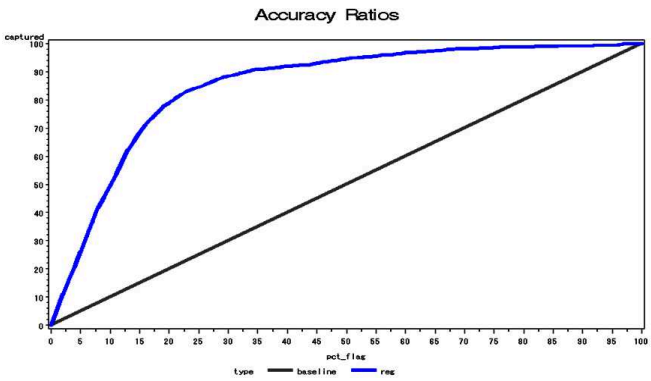

Fig. 1 AR value is 0.73

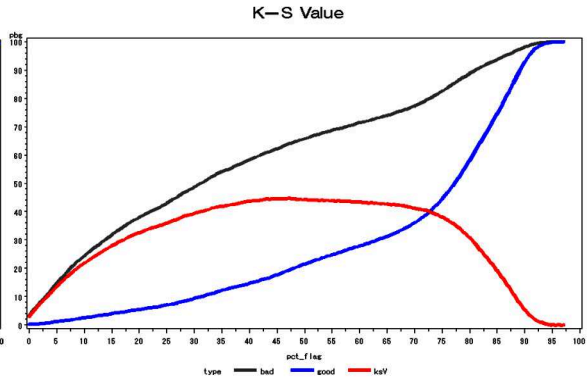

Fig. 2 Model Checking KS value

Table3 KS score sheet

Score	Cumulative target customers(CC)	Cumulative non-target customers(CNC)	Cumulative total client(CTC)	CC/ CTC	CNC/CTC	KS values
47	5812	218488	224300	63.87515112	19.19683415	44.678

Verify the correct rate and the feasibility to the model. This article randomly selected 10 customer data in the sample to test and verify substituting classification function, and then we obtain the results whether the customer has been lost, as shown in Table 4.

Table 4 Customer churn prediction analysis table

Customer ID	Var1 Assets	Var 2 Market cap	Var 3 Funds	Var 4 Positions	Var 5 Growth rate	Var 6 Than	Var Worse than	Outflow (Y)
100739135	1	0.2232	0.1713	0	8	80	6.25	1
100916315	3	0.1247	0.7521	2	1	30	-0.025	0
...	...	...	...	...	...	...	...	...
2760963	2	0.3369	0.2227	0	5	90	5.02	1

From the table, we can get the following conclusions: Customer ID100916315 variable difference ratio less than 0, that means the ratio of the loss of customers and normal customers less than 0, value of (Y) is equal to 0(loss or not), means that the customer has been lost. Contrary, the difference ratio of other nine customers is greater than 0, then Y=1, means that customers is not loss, so the conclusion of customer churn analysis by Logistic regression model are consistent with the actual situation.

Conclusion

This paper studies how to use data mining technology to establish customer churn prediction model to solve the problem of customer loss experienced by a securities firm. Real data was

collected and analyzed to design the model of the customer churn prediction using the Logistic regression method. The findings of the study provide countermeasures and recommendations for effectively improving customer turnover.

Keywords: Pull and Drag Transportation; Customer Operation Center; Site Selection; AHP

Abstract. Pull and drag transportation is an advanced transportation organization ,it is lower transport costs, higher efficiency, better energy saving. Customer operation center is important nodes in the pull and drag transportation routes, related to the overall layout of the transportation network and the overall effectiveness. Using AHP in this article, take full account to needs of pull and drag transportation , and analysis the main influencing factors about customer operation center location from the perspective of society and the business. Established model, obtains the importance weight of the influence factors, and provide the basis for evaluation. This method makes the selection process efficient, reasonable, and has a certain practicality.

Introduction

1)Introduction of Pull and Drag Transportation.(1)Basic situation of pull and drag transportation: Pull and drag transportation is a transportation organization, the tractor pull a trailer to the destination, unload the trailer and put a new trailer, then transport to another destination of transportation. The tractor and the trailer (or semi-trailer) separate and combine , match and schedule, according to this way, the transportation organization can short the loading and unloading time, the tractor increase frequency of use. Compared with the traditional modes of transportation, lower transportation costs, higher efficiency, faster turnaround of vehicles, better energy-saving and emission reduction effect . It will become the mainstream mode of transportation[1].

(2)Pull and drag transportation - customer operation center model: Large-scale logistics enterprises mainly use this pull and drag transportation mode: in the customer operation center, the special line vehicles collect cargos from customers together, the cargos is loaded into the trailer in advance, then put the trailer to a tractor, then the cargos are transported to port operation center; in the port operation center, remove the trailer after arrival of the tractor, then the special line vehicles transport the cargos to the yard and waiting for export, it is the whole process of transportation.

Port operation center set up in a major port around, play a major focus like receiving import containers from the port and sending export containers, the site selection has a strong unique. Customer operation center play a role of logistics nodes in pull and drag transportation routes; the transfer point of different transport tools; cargos transit hub; goods production, processing, commerce and trade, transportation and distribution logistics nodes , as shown in Fig 1.

2)Research Significance on Site Sellection of Customer Operation center. Customer operation center is a logistics node in pull and drag transportation routes, it is important place of providing logistics services. Through setting up more than one customer operation center, can form a reticular pattern, prompt intensive transportation and economies of scale, and achieve reverse logistics and cycle-logistics. Site selection of customer operation center is left hanging of cycle-logistics in mind for the future.

Study on site selection of customer operation center not only directly help logistics infrastructure planning and construction, but also indirectly promote the development of China's logistics industry, and promote regional economic development, ease the pressure on urban traffic, protect the natural

environment, has positive significance. The study provide better theoretical basis and reference materials . Therefore, the logistics facility location problem and its method of research is extremely important significance.

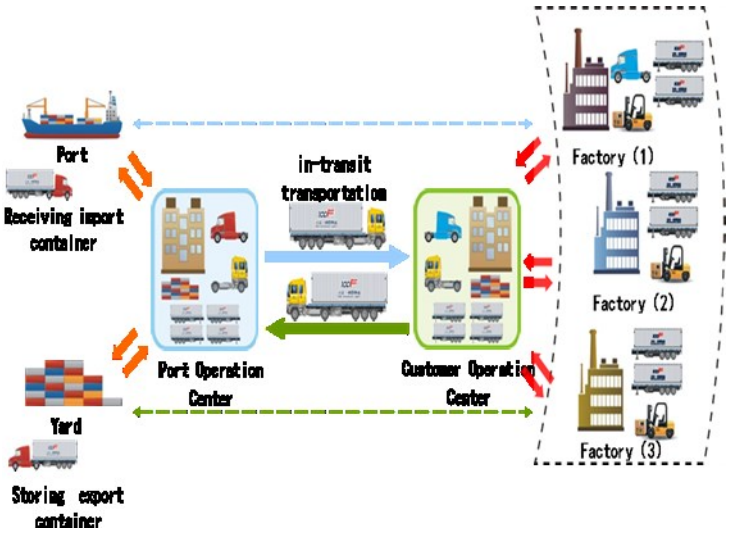

Fig 1 Pull and Drag Transportation- Customer Operation Center Model

3) Research Methods.Customer operation center needs larger-scale. So, its construction and operation of logistics enterprises will not only affect their own development, but also has a certain degree of economic and ecological environment of the surrounding areas. The site selection is a complex decision problem, involving a number of factors, solely relying on quantitative analysis or qualitative analysis, are difficult to arrive at a scientific and rational evaluation, the results are difficult to use.

AHP is a multi-criteria decision making method by combining quantitative analysis with qualitative analysis. In the 1970s , American operations research professor establishes this method .It will be a complex multi-objective making decision as a system, the target reduces to multiple targets or guidelines, then divide into multiple indicators (or criteria, constraints) of a number of levels, calculate the single level sorting and the total level sorting by qualitative indicators of fuzzy quantification method, as a target(multi-index) and method optimization decision system. The key is to build matrix, and judge the matrix. Rationality and scientific nature of matrix impact to its application effects directly.

This article uses the basic principle of AHP, site selection of customer operation center is the target site, and build location model by full analysis of the factors, then valuate the programs one by one, and obtain the solution by using Matlab software, finally, find the best construction site.

AHP Analysis

1)Establishment of Evaluation Indicators Systems. Many factors affect site selection of customer operation center. But the site has the Special Operation center on the premise of pull and drag transportation. For example, the site should close to customer-intensive places, reduce transport time of the special line vehicles, and have adequate supply; and maintain a certain distance between customer operation centers; area of customer operation center is enough, and so on. The influence factors of location is summing up two factors into social and enterprise perspective by analytic hierarchy process[2], as shown in Fig 2.

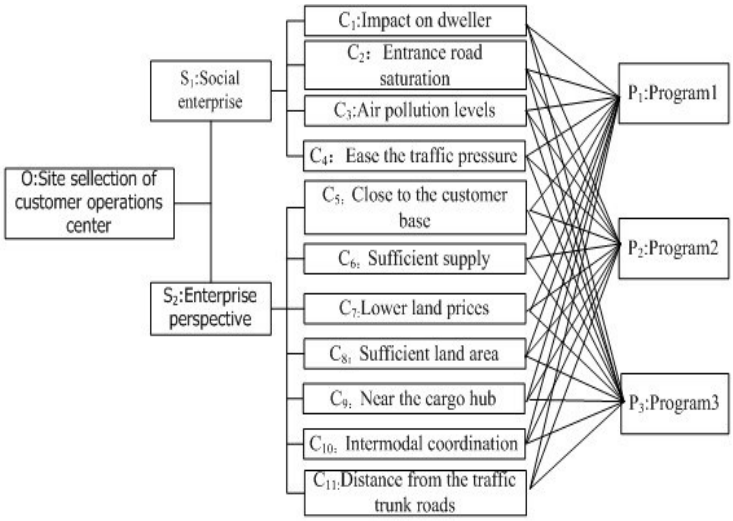

Fig 2 Hierarchy System of Site

2)Establishment of Judgment Matrix . In site selection of customer operation center, the target layer O is impacted by two making factors S_1 and S_2, however, these two factors are affected by the various sub-factors. Through group decision-making by the experts, establish the matrix structure according to the relative importance of factors[3].

(1) Judgment matrix O-S: For a target layer O, S_1 and S_2 are equally important, so judgment matrix O-S is: $A=\begin{bmatrix}1 & 1\\ 1 & 1\end{bmatrix}$.

Maximized eigenvalue: $\lambda_{max}=2$, priority vector:$W_1=(0.5,0.5)^T$.

(2)Judgment matrix S_1-M: $A=\begin{bmatrix}1 & 3 & 1/3 & 1/5\\ 1/3 & 1 & 1/5 & 1/7\\ 3 & 5 & 1 & 1/3\\ 5 & 7 & 3 & 1\end{bmatrix}$;

Volume normalization, $B=\begin{bmatrix}0.107 & 0.188 & 0.074 & 0.119\\ 0.036 & 0.063 & 0.044 & 0.085\\ 0.321 & 0.313 & 0.221 & 0.119\\ 0.536 & 0.438 & 0.662 & 0.597\end{bmatrix}$;

Priority vector :$W_2=[0.122,0.057,0.263,0.558]^T$. Maximized eigenvalue: $\lambda_{max}=4.117$.

Therefore, relative to the social benefits, the four factors should be sorted according to the weight of C_4, C_3, C_1, C_2.

(3)Judgment matrix S_2-M:$A=\begin{bmatrix}1 & 1/5 & 5 & 2 & 3 & 7 & 3\\ 5 & 1 & 7 & 3 & 5 & 8 & 5\\ 1/5 & 1/7 & 1 & 1/3 & 1/4 & 3 & 3\\ 1/2 & 1/3 & 3 & 1 & 3 & 5 & 3\\ 1/3 & 1/5 & 4 & 1/3 & 1 & 4 & 3\\ 1/7 & 1/8 & 1/3 & 1/5 & 1/4 & 1 & 1/3\\ 1/3 & 1/5 & 1/3 & 1/3 & 1/3 & 3 & 1\end{bmatrix}$;

Volume normalization, $B=\begin{bmatrix}0.133 & 0.091 & 0.242 & 0.278 & 0.234 & 0.226 & 0.164\\ 0.666 & 0.454 & 0.339 & 0.417 & 0.390 & 0.258 & 0.273\\ 0.027 & 0.065 & 0.048 & 0.046 & 0.019 & 0.097 & 0.164\\ 0.067 & 0.151 & 0.145 & 0.139 & 0.234 & 0.161 & 0.164\\ 0.044 & 0.091 & 0.194 & 0.046 & 0.078 & 0.129 & 0.164\\ 0.019 & 0.057 & 0.016 & 0.028 & 0.020 & 0.032 & 0.019\\ 0.044 & 0.091 & 0.016 & 0.016 & 0.026 & 0.097 & 0.055\end{bmatrix}$;

Priority vector:W_2'=[0.196,0.399,0.067,0.152,0.107,0.027,0.054]^T. Maximized eigenvalue: λ_{max}=7.727.Therefore, relative to the enterprise benefits, the seven factors should be sorted according to the weight of C_6, C_5, C_8, C_9, C_7, C_{11}, C_{10}.

3)Consistency Check of Judgment Matrix. Consistency Index is CI=$\frac{\lambda_{max}-n}{n-1}$.Based on the average random consistency index RI values (Table 1), obtains relative consistency index CR=$\frac{CI}{RI}$, When the CR is less than 0.1, the sort result has a more satisfactory level of consistency and accept the result of the analysis, or to determine the matrix of adjustment, and re-find the right system according to the above steps[4], as shown in Table 1.

Table 1 RI Value

Size(n)	1	2	3	4	5	6	7
RI	0	0	0.58	0.9	1.12	1.24	1.32

The above 3 matrix carry out consistency check .

(1)Judgment matrix O-S: λ_{max} =2,so this judgment matrix has a satisfy consistency check obviously.

(2)Judgment matrix S_1-M: CI= $\frac{\lambda_{max}-n}{n-1}=\frac{4.117-4}{4-1}=0.03949$, CR=$\frac{CI}{RI}=\frac{0.03949}{0.9}$=0.04388<0.1.So this judgment matrix has a satisfy consistency check.

(3)Judgment matrix S_2-M: CI= $\frac{\lambda_{max}-n}{n-1}=\frac{7.727-1}{7-1}=0.12122$, CR=$\frac{CI}{RI}=\frac{0.12122}{1.32}=0.09183$<0.1. So this judgment matrix has a satisfy consistency check.

Site selection of customer operation center is divided into four hierarchical structure: the target layer O, criteria layer S, sub-criteria layer C and program layer P. According to calculate all the factors of the same level to the overall goal, obtain the relative weight of sub-criteria layer C to the overall goal O. Its value is obtained by combination of W^1 and W^2:

$W=\begin{bmatrix} W_1 & 0 \\ 0 & W_2 \end{bmatrix}$,W=[0.061,0.028,0.132,0.279,0.098,0.200,0.033,0.076,0.053,0.014,0.027]^T. In the site selection of customer operation center, the order of importance is easing traffic pressure, sufficient supply, air pollution levels, close to the customer base, sufficient land area, impact on dwell, near the cargo hub, entrance road saturation, distance from the traffic trunk roads, intermodal coordination.

Of course, the program should also be established judgment matrix after proposing the specific program, and obtain synthetic weight of the program layer on the overall goal, finally identify specific and practical solutions by the weight sort of various programs[5].

Conclusion

According to site selection of customer operation center, AHP can make the complex decision-making clarity, simplicity, ability to easily and accurately to select the optimal program. It is an effective method.

Keywords: Layout of Integrated Freight Hub; Attribute Prediction; Hierarchical Division

Abstract. Applying transportation planning theory and operations research method , this paper proposes the layout model of integrated freight hub with two-stage , which first builds a model to predict the attributes of integrated freight hub aiming for the optimization of regional freight transportation organization , and then works out the way to classify district integrated freight hub based on Hierarchical cluster. Eventually, take a specific example for empirical study.

Introduction

China's economy and society enter a new stage of development during the "Twelfth five-year" period, which is a crucial period of building a well-off society. In the process of accelerating the transformation of economic development mode , the industrial structure and product structure in our country will continue to upgrade, which inevitably requires building low-cost, efficient transportation system, providing efficient, fast and safe transportation services. In this modern transportation system, a single mode of transportation hardly meets the customer's needs.

Integrated freight hub, the intersection of various modes of transportation, is the core to integrated transport infrastructure. It is possible to join modes of transport effectively, and break the barriers between the modes of transportation by the planning and construction of integrated freight hub in a sound approach, which is conducive to realize the integration of transport, and make full use of all traffic resources, reasonably organize the flow of goods from each direction, reduce transportation costs, cut down the environmental pollution and energy consumption produced by the traffic[1].

Principle and design on the layout of integrated freight hub

This paper assumes that freight transport demand matrix is known. Therefore, according to the planning objectives , integrated freight hub layout model can be divided into prediction of integrated freight hub attributes and classification of integrated freight hub level , specific train of thought is shown in figure 1 below.

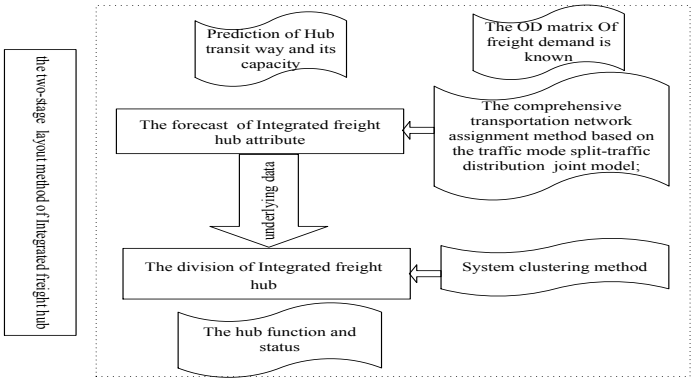

Figure 1 The Two Stage Model of Integrated Freight Hub Layout

Establishment of the layout of integrated freight hub model with two-stage

1)Establishment of the attribute prediction model of the integrated transport hub

Assumptions. As the integrated transportation flow assignment model is serving the layout of the integrated freight hub, the following boundary conditions and the basic assumptions are advanced according to the characteristics and requirements of hub layout.

(1) Goods OD demand matrix is known and time unit is one year.

(2) The generalized transportation costs is known.

(3) There is a positive correlation function relationship between general freight transportation cost and freight traffic volume in practice, namely , the greater freight traffic volume in line the greater the generalized transport cost of the goods per unit. But it is difficult to express the relationship , and there is little inflection of freight general expenses while considering the capacity constraints. Therefore, t The generalized transportation costs is fixed, not affected by freight traffic volume in the model[2].

(4) Taking no account on the effect of generalized cost about differenct kinds of goods, that is to say, transportation cost per unit of Transportation costs, time value, risk cost are only related to transportation mode and path, nothing to do with cargo type.

(5) To eliminate variances of the transport node cost, and to reflect the real status of transportation node in the comprehensive transportation network, all the generalized transport costs are the average cost of the transport node area which is known.

(6) The capacity attributes of the transport line all modes of transport are known; the location of the various transport node of all modes of transport are known,but the capacity attributes are infinite.

(7) Transit of cargo in the node is defined as instant transfer, regardless of the storage time of the goods in transport hub node, for the continuity of transport.

(8) The goods in a transportation node transit once at the most.

The relevant variables and parameters. In order to clear description of this model，the definitions and explanations on the relevant variables and parameters can be noted as follow：

$G=(N,A)$ denotes a multi-mode integrated transportation network of multi-class cargoes. N is nodes set, A is united arcs set, $a \in A$ is one arc in integrated transportation network. The transport arcs of integrated transportation network includes transport arc $\overline{A}$ and dress arc $\overline{A}'$, namely $A=\overline{A}\cup$; for $a \in A$, C_a denotes transport capacity of arc a, $C_{a'}$ denotes the line transport arc, $C_{a''}$ denotes the node transit arc。According to the above hypothesis, the node transit arc capacity is infinite. R is the set of all cargoes' OD flow origin point, $R \in N$; S is the set of all cargoes' OD flow destination point, $S \in N$; RS is the set of all cargoes' OD flow in the whole network, rs is some determined cargo OD flow, $rs \in RS$. K_{rs} (K) is all optional routes set of cargo, k_{rs} (k) is No. k route of cargo p between r and s in OD flow, $k_{rs}^{p} \in K_{rs}^{p}$; f_k^{rs} means No. k route's freight volume between r and s in OD flow; C_k^{rs} is No. k route's generalized transportation costs; $\delta_{a,k}^{rs} \in \{0,1\}$ is 0-1 variable, which equals to 1 if No. k route k_{rs}^{p} includes united arc a, if not the value is 0[3].

Establishment of the optimization model. For preparing for the reasonable division of the hub function and level, the mathematical model for a reasonable forecast of the cargo throughput in each mode of the the integrated transportation hub can be obtained:

$$\min C=\sum_{r\in R}\sum_{s\in S}\sum_{k\in K} f_k^{rs} C_k^{rs} \tag{1}$$

$s.t.$

$$\sum_{r\in R}\sum_{s\in S}\sum_{k\in K} f_k^{rs}\delta_{a',k}^{rs} \le C_{a'} \qquad \forall a' \in A' \tag{2}$$

$$\sum_{k\in K} f_k^{rs} = q_{rs} \qquad \forall r \in R, s \in S \tag{3}$$

$$f_k^{rs} \ge 0 \qquad \forall r \in R, s \in S, k \in K \tag{4}$$

$$\delta_{a',k}^{rs} \in \{0,1\} \qquad \forall r \in R, s \in S, k \in K, a' \in A' \qquad (5)$$

In the above model, formula (1) is the target function of math model, which denotes the total freight volume among all OD points transported with minimum generalized transportation costs; formula (2) to (5) are constraints, in which formula (2) is volume constraint of transport arc , but the node transit arc capacity is unlimited; formula (3) is relationship constraint of cargo OD to route traffic volume; formula (4) is non-negative constraint of cargo OD to route traffic volume; formula (5) is logical relationship constraint between routes and arcs.

2)Integrated freight hub classification model based on Cluster analysis

Clustering analysis, is the progress that different objects with various characteristics can be divided into multiple classes of objects, which also apply to integrated freight hub classification. At present, the k-means clustering method and system clustering method have been widely applied in research. By employing K - average clustering method, it is needed to predetermine points on the number of categories, and the whole process of clustering will not be reflected, moreover, the properties of the sample had better not more than 3[4]. While applying system clustering method, it is likely to cluster gradually, and demonstrates the whole process by clustering hierarchical graph. As the layers of integrated freight hub is uncertain, and the attributes of the streamline is more than 3, this paper employ the system clustering method for clustering.

Solution of the integrated freight hub layout model with two stages

1)Solution of integrated transport hub attribute transportation model based on equilibrium assignment network.

Solution of the model can be divided into the following two steps:

(1) Seek several paths to be candidate. According to the objective function, if arc transport capacity constraints are infinite, every OD flow of goods is the path with minimum generalized transportation cost only, namely the short circuit. But, if taking cost of its minimum for each goods od flow into account, regardless of capacity constraints of transport lines, cargo flow may exceed its capacity, which is not in conformity with the actual.Therefore, in real life, some goods time OD flow would choose the second short circuit, the third short circuit,... , the kth short circuit for transportation, transportation policy makers often make choice in several candidate transport path, even some transport path is not in the scope of the candidate.

(2) Selecting transportation route by genetic algorithm to get the minimum generalized transport cost. The optimal transport path of each goods OD flow can be chosen by genetic algorithm with the goal of system optimization, eventually minimizing the sum of generalized transportation cost of the goods OD flow[5].The genetic algorithm flow is shown in figure 2.

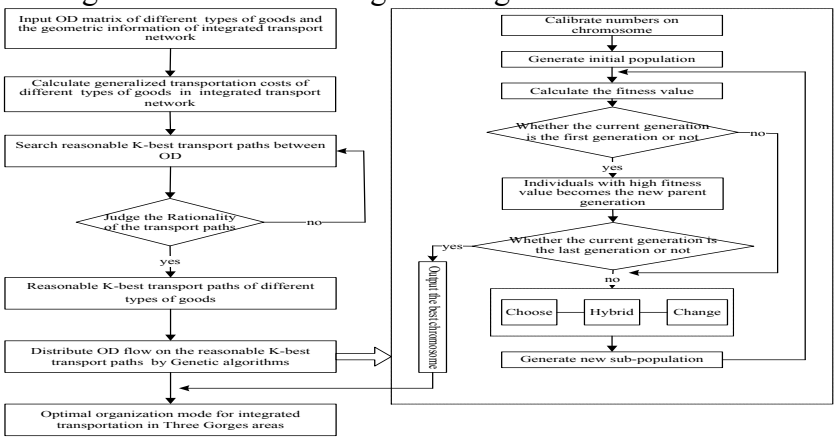

Figure 2 Flow diagram of Genetic algorithms based on reasonable K-best transport paths

2)Solution of Integrated freight hub classification model based on Cluster analysis.

There are four kinds of Clustering algorithm: direct clustering method, the shortest distance clustering method, the farthest distance clustering method, the average clustering method. As it is easy to expand or contract by applying the shortest and longest distance method. And the average

distance method is neither applied to shortest distance or longest distance. Take the middle distance between the two, avoiding the disadvantages of calculation with the shortest and longest distance. This article employs the average distance as a integrated freight hub layout of clustering algorithm.

Numerical example

In a regional transportation network, there are 8 integrated freight hubs.The hub location and layout of transportation physical line is known. The capacity of transportation lines is symmetrical in this examples, shown in the figure 3 below.

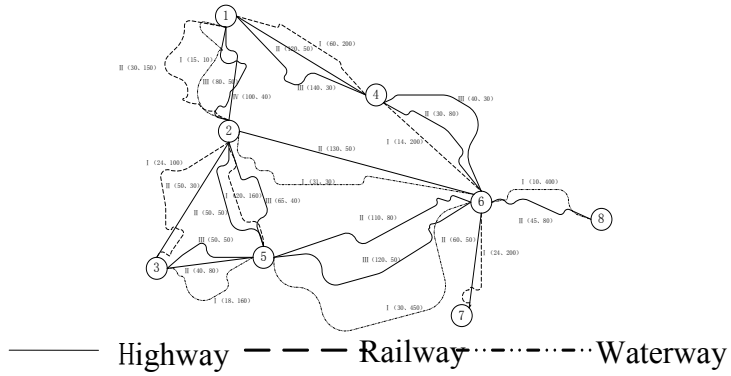

Figure 3 Regional integrated transport network cost

Regional transportation demand OD districts are divided by the location of the integrated transportation hub. OD demand matrix is symmetric matrix without considering internal travel in a district, transportation demand OD matrix are shown in table 1.

Table 1 Regional Transportation Demand OD Matrix (unit: ten thousand tons/year)

O/D	1	2	3	4	5	6	7	8	summation
1	0	25	20	25	20	40	5	30	165
2	35	0	20	15	25	25	15	20	145
3	20	20	0	15	20	30	10	25	140
4	25	15	15	0	15	25	20	20	135
5	20	25	20	15	0	25	15	30	150
6	40	25	30	25	25	0	35	50	230
7	5	15	10	20	15	35	0	15	115
8	30	20	25	20	30	50	15	0	190
Summation	165	145	140	135	150	230	115	190	1270

Based on a reasonable candidate paths, road traffic prediction results as shown in figure 4.

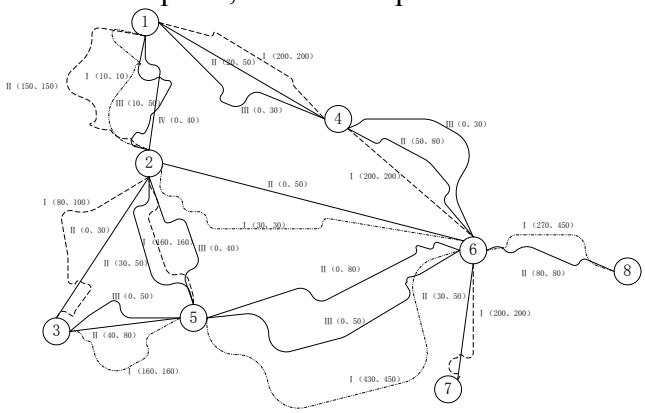

Figure 4 Regional Integrated Transport Network Section Flow Diagram

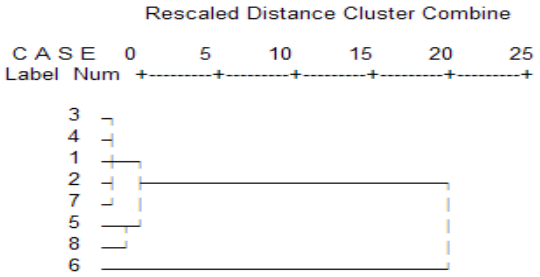
According to the result of layout flow the integrated transportation hub traffic, integrated transport hub traffic prediction result are shown in table 2.

Table2 Integrated Transport Hub Traffic Prediction Result Table

NO.	Total flow	Transit flow				Local flow			
		Total	H-W	R-W	H-R	Total	H-H	H-W	H-R
1	330	0	0	0	0	330	30	10	290
2	290	0	0	0	0	290	40	20	230
3	280	0	0	0	0	280	40	160	80
4	270	0	0	0	0	270	70	0	200
5	400	100	30	70	0	300	40	170	90
6	690	230	0	230	0	460	130	180	150
7	230	0	0	0	0	230	30	0	200
8	380	0	0	0	0	380	80	300	0

This paper classifies the integrated hub by applying the clustering procedure and the system clustering method, clustering spectrum figure shown in figure 5.



Fgure 5 Spectrum Graph Clustering

According to classification rules of spectrum graph clustering, this paper choose clustering hierarchy for 3, specific clustering results are shown in table 3.

Table 3 Classification of Integrated Freight Hub Level Table

Classification	NO
Fisrt	6
Second	5, 8
Third	1, 2, 3, 4, 7

According to the results of the clustering analysis on the characteristics of different levels integrated freight hubs, the classification of the regional integrated freight hub is as follows:

1) Regional core freight hub.
2) Regional important freight hub.
3) Regional general freight hub.

Conclusion

After analysis of the above result, it is appropriate to draw conclusion as below:

1) The key of transit of freights between the two adjacent nodes (freight hub) is the distance. While the length of line is almost the same, the costs of transit lines identify with the rule that the cost of transportation from high to low is waterway, highway, railway in turn. However ,freights by waterway-railway transit should be transit in freight hub by highway, as the freights can be transported from door to door, which it is hardly to reach for railway. While transport distance is relatively close between two adjacent nodes, the shipper usually choose highway such as the flow between node 3-5, 4 - 6, 6 - 8 of the goods for transportation cost savings. While transport distance is distant between two adjacent nodes, the cost of waterway-railway transit is lower than highway, the shipper will choose waterway-railway transit, and transit in the destination, such as flows between 5 to 6, 6-7.

2) Whether the freight flows between two freights hub need to be transferred, first, is due to if there is a direct route between two nodes, mainly referring to the existence of direct path with lowest cost. If so transfer is unnecessary,and If not, to compare the cost between the direct route between two points and transit lines, such as node 4 to 5, 4 to 8, 5-7, the goods traffic between finally are transferred in hub 6.

3) The status of the freight hub is decided jointly by the quantity of local freights and transfer freights. Local freights flow represents the development of economic and industrial and the advantage of resource regionally. the more advanced the economy, the higher residents' average income, the stronger consumption ability, the demand of product are larger, The more advanced the industry, the higher production capacity, the more raw materials are needed for the product; the oil-rich region of output will create a big demand for transportation. transit freight, can represent integrated freight hub location advantage of transportation, also manifest attraction of freights from different direction, which is also the important influencing factors of its level status.

4) The railway-highway transit hub play a important role in the integrated freight network. Among all hub, most freights are transited between railway and highway in hub6 or hub 5, which join the east-west waterway and north-south railway, is key to the efficiency of the regional integrated freight network.In various modes of transportation, the cost of water transportation in long distance is lower than other one, however , it is not always to transport by water as its high requirement of natural conditions. Compared with other modes, railway is a good choice for its big capacity and low cost. So the railway-highway transit hub play a important role in the integrated freight.

Abstract. Distribution is an important function of enterprise logistics. Through efficient distribution activities, it can reduce the total cost of logistics enterprises and improve logistics efficiency and service levels. Therefore, the rationality of the logistics and distribution system design will directly affect the survival and development of enterprises. In this dissertation uses a retail business distribution network for the study, to study its distribution optimization models and methods, using a variety of algorithms for analysis, to understand its distribution network efficient mode of operation.

Introduction

Business logistics and distribution system, is supported by a wide range of information to achieve information-based logistics axis systematic[1].The former includes the transport, handling, distribution, processing, packaging and other functions. It seeks labor-saving and efficiency. The latter includes the ordering, delivery, and management of the library and other functions, and strives to complete the commodity flow of information activities throughout the process. However, the inherent characteristics of modern distribution systems that it is generally considered by us, in order to achieve the purpose of efficiency and effectiveness of logistics. And it uses low cost and excellent customer service to complete physical activity from the supply of goods to the point of consumption. On the operational side, through organic links and interactions of the operating subsystems and information subsystems to achieve logistics system optimization. Distribution system is a whole that composed by a variety of different elements, each element interrelated and role in the formation of many functional modules and subsystems at all levels, so that the whole system presents a multi-level structure and reflects the inherent system characteristics.

Retail business and distribution activities according to the needs of retail storeBusiness conducts[2] and it before delivery must to make the necessary rationing. The range of distribution is generally limited to a particular city or region[3]. Therefore, the retail business and distribution activities are in the logistics branch or the end of the social system. And is close to the consumer's logistics activities, is a key part of the retail Business management control, is not a simple storage and transport.

The delivery system of this do not stay Shipping includes a total of three parts:

(1) Efficient distribution center. The suppliers of the a retail business according to the order of each branch will be delivered to retailers of goods distribution center[4]. And distribution center is responsible for completing the screening, packaging and sorting of the goods[5]. The distribution centers of a retail business has highly modern mechanical facilities. In addition to the 85% of goods are used mechanical treatment, which greatly reduces the cost of manual handling of goods. Also, due to the huge number of purchases of commodities, it makes full use of automation equipment and fully demonstrates the advantages of scale.

(2) Rapid transport system. In the entire logistics chain, transport links is the most expensive part. In order to reduce transport costs and improve efficiency, a retail enterprises to adopt a method they own the team, and with a global positioning tech management tools for the assistance. And it ensure that the team is always in an accurate, efficient, fast, full load condition. The practice of a retail business can effectively reduce transportation costs[6], mainly in two aspects: On the one hand, it reduce the high costs of uncontrolled vehicle suppliers of intermediate links and transport links in the middle of exploitation; On the other hand, it ensures that a retail business to take place between the

distribution center and various shops transport master mastership, the ability to goods such as cars, shops and other goods and other undesirable phenomena to a minimum, try to make the delivery and distribution center receipt of each store to do a smooth, non-overlapping convergence, the distribution costs to a minimum.

(3) Rapid delivery process. After receipt of the distribution center and aggregated customer orders, we must first determine the type and quantity of goods, and then check the inventory of goods through the system, if the spot, then transferred to the sorting operation. After the suppliers send the goods to the distribution center, after checking procurement plans, it need commodity inspection (including the quantity, quality and acceptance) and other procedures, and then need sent to a different location to store shelves, when a commodity is stored in. Each time, the computer will put their location and number eleven recorded; proposed plan to goods, the computer system will identify needed to the product storage location, and print shops code label and affixes to the product in the future. Distribution center according to each store requires screened the goods, re-packaged, from the distribution area shipped to free zone[7]; whole package of goods on the shelves sent directly to the conveyor belt, scattered goods also sent by personnel after removal from the bench to the conveyor.

A retail business model and methods described in logistics

The retail business multi-path transport Transportation-VRP model. Multi-path transport transportation problem is the reality of very common deployment problems, especially for a large number of clients' entity. For example, a enterprises which has thousands of suppliers. Such core issue is how to allocate the vehicle scheduling. Therefore, VRP (Vehicle Routing Problem) models have emerged, became solve the problem of a multi-transport path very successful model[8]. The problem research objectives are: design appropriate route for a series of retail stores demand points , the vehicle in an orderly manner through these routes, to meet certain constraints (such as the demand for goods, delivery volume, vehicle capacity constraints, mileage restrictions etc.), up to a certain optimization goals (such as mileage shortest minimum cost, time, as little as possible, etc.). It involves the selection and path of a multi-vehicle transport service object identified two aspects.

A typical VRP model can be expressed as follows:

(1) Basic Conditions There are m identical vehicles parked vehicle in a common source, it needs to provide the n goods stores, stores as. $v_1, v_2, \ldots, v_n$

(2) Model target Determine the required number of vehicles is N, and assign these vehicles to a transport path, while including path and scheduling transportation route within the total minimum cost.

(3) Limiting condition: N is not more than m. Each store must be served. Vehicle must be returned upon completion of the task source v_0. Can not exceed the capacity limit of the vehicle; Special issues need to be considered when the window limit; Transportation Regulations.

Saving Algorithm. Saving algorithm (Saving Algorithm) is used to solve the transport vehicle uncertain VRP problem, which is currently used to solve the VRP model best known heuristic algorithms.

The basic principles of saving algorithm.The core idea of saving algorithm is to save two transport path of the transport problems that exist in (0, ..., i, 0) and (0, j, ..., 0) merged into a transport path (0, ..., i, j, ... , 0). In the merge operation above, the total transportation distance of throughout the transportation problem will change, if the change of total transportation distance decreased that claimed savings in transportation distances. Corresponding change value, called savings distance ΔC_{ij}

Like formula (1) shown in:

$$\Delta C_{ij} = c_{io} + c_{oj} - c_{ji} \tag{1}$$

The main steps of the algorithm mileage savings. Known conditions: Stores demand point set $N_R = \{1,2,\ldots, n\}$, Each point demand stores R_i ,The shortest distance between the points c_{ij} .

First, it is the initial formation of a solution. Determine the vehicle delivery point set.

$I_1, I_2, \cdots, I_m$

Allow $I_j = \{j\}$, j =1,2,…,n(First take a single point of delivery)

Second, it is the calculation of savings. Calculate the degree of savings on all points, ΔC_{ij} and the calculated results in ascending order.

The third step is to merge the transport path. Starting from the value of the degree of sequence conservation in ascending order of the top until the ΔC_{ij} queue is empty mileage savings far. Repeat the following steps: Follow-saving mileage queue in descending order, analyze the possibility of the merger between stores i and j (meets the load restrictions, not in the same path, and the combined number of no more than 2), the i, j linking to order. Then can let $I_i' = I_i \cup I_j; I_j = \varnothing$ 。 If not, the queue is removed from the current mileage save savings mileage, Analysis of a path.

Scanning Algorithm

Scanning algorithm (Sweep Algorithm) is also used for VRP which does not limit the number of vehicles, and conservation algorithm is different that it belongs to the sub-heuristic algorithm, while saving algorithm is constructed algorithm.

The basic principle of scanning algorithm. Scanning algorithm is a first packet route algorithm. The so-called grouping, namely a set of points assigned to each vehicle. A simple grouping method is dividing the coordinate plane into a plurality of fan-shaped area which of is the distribution center will be the origin, and initially will be distributed to area points of each sector of a car, and then expand the route. If during the first - the grouping line route structure, there is still unallocated point, then run the "group - Route program. Repeat until all the points are allocated.

The main steps of scanning algorithm. (1) Starting 0:00 in the polar coordinate system as the origin, the connection of a connected graph is defined and any one of the stores and the origin point zero angles to establish polar coordinate system. Then the locations of all the stores are located, polar coordinate transformation.

(2)Grouping From the perspective of the smallest stores to start building a group, counterclockwise, the stores added to the group one by one, until the total demand exceeds the limit stores load. Then continue to build a new group, continues counterclockwise, and then join the suppliers to the group.

(3) Repeat (2) the process until all the stores have been classified.

(4) Path Optimization Single transport path within each group carry out a path optimization.

The improved method recently inserted

Recent insertion method is an algorithm for solving TSP problem. Recently completed insertion method consists of four steps:

(1) Find the c_{0i} minimum node v_i, and forming a sub-tour, $T = \{v_0, v_k, v_0\}$ 。

(2) In the rest of the nodes to find the path of an ion transport nearest node A node v_k

(3) Find an arc (i, j) in the sub-transport path, such that $c_{ik} + c_{kj} - c_{ij}$ Minimum, then the node v_i into the Node v_i, and between v_j, with two new arc (i, k), (k, j) instead of the original arc (i, j), and the node v_k is added to the sub-transport path.

(4) Repeat steps (2), (3), until all nodes are added to the sub-transport path.

Thus, the sub-transport path evolved to a TSP solution. Insertion method to solve the transportation problem is a single transport path, so this approach on the basis of improvements and fixes, so that it can solve the multi-path transport transportation VRP problem .The improvement is as follows:

(1) Find the c_{0i} minimum node v_i, and forming a sub-tour, $T = \{v_0, v_k, v_0\}$ 。

(2) In the rest of the nodes in the path to find a particular ion transport nodes nearest node v_k. If the total freight transport path at this time does not exceed the load limit car, then proceed to step (3). Otherwise, go to (1) find a new one transport path.

(3) Find an arc (i, j) in the sub-transport path, such that $c_{ik} + c_{kj} - c_{ij}$ Minimum, then the node v_i into the Node v_i, and between v_j, with two new arc (i, k), (k, j) instead of the original arc (i, j), and the node v_k is added to the sub-transport path. If at this time the total distance of the transport path of travel of the vehicle does not exceed the limit, then proceed to step (4). Otherwise, go to step (1), to find a new one transport path.

(4) Repeat steps (2), (3), until all nodes are added to the sub-transport path.

Summary

The existence of large-scale retail enterprises benefits inherent drive to expand the business to market and implement regional development strategy. Therefore, the complex multi-stage distribution network design and heuristic algorithms for solving large-scale problems of such a study will be the direction. For large-scale retail enterprises actual distribution system is extremely complex, vague and random uncertainties exist two types of the actual system.Therefore, the study of large-scale retail distribution system optimization under uncertainty decision to establish the appropriate mix of fuzzy random chance-constrained programming model and design appropriate and effective algorithm, will be the direction for further research.

Keywords: Rough set, Attribute reduction, Decision table, Discernibility matrix.

Abstract. The main idea of rough set theory is to extract decision rules by attribute reduction and value reduction in the premises of keeping the ability of classification. This paper presents the design of model for customer division based on rough set, and uses algorithms for attribute reduction and rule extraction in rough set to analyze the customer of supermarket. This paper also introduces how to achieve the minimum result of attribute reduction and decision-making via decision-making report, winkling redundant attribute and over-rule of decision.

Introduction

RFM [1] is an analytic technique for customer division in marketing management.It chooses important factor from numerous customer information to analyse and simplifies models and reduces complexity. In this paper, a customer division model based on rough set was designed.And using the method of attributes reduction and rules extraction method of rough set, combined with case analysis and the reduction of the customer features, classification rules were obtained to allow businesses to understand customer value and provide the basis for decision support.Rough set is a commonly used data mining tools proposed by Pawlak [2] in 1982, rough sets are used to study intelligent systems that are characterized by insufficient and incomplete information. Rough set theory has been successfully applied to the fields of artificial intelligence including machine learning, pattern recognition, decision analysis, process control, knowledge discovery in databases, and expert systems [3]. Here are some basic concepts about rough set.

Preliminaries

Information System and Decision Table. Let $I=(U; A)$ be an information system, where U is a non-empty set of finite objects (the universe of discourse); A is a non-empty finite set of attributes such that $a: U \rightarrow Va$, $\forall a \in A$; Va being the value set of attribute a. In a decision system, $A=\{C \cup D\}$ where C is the set of conditional attributes and D is the set of decision attributes. With any $P \subseteq A$ there is an associated equivalence relation $IND(P)$ [1]:

$$IND(P)=\{(X,Y)\in U^2 \mid \forall a\in P, a(x)=a(y)\}. \quad (1)$$

The partition of U, generated by $IND(P)$ is denoted U/P and can be calculated as follows:

$$U/P=\otimes\{a\in P: U/IND(\{a\})\}, \quad (2)$$

where

$$A\otimes B=\{X\cap Y: \forall X\in A, \forall Y\in B, X\cap Y\neq\varnothing\}. \quad (3)$$

If $(x, y)\in IND(P)$, then x and y are indiscernible by attributes from P. The equivalence classes of the P-indiscernibility relation are denoted $[x]_P$. Let $X\subseteq U$, the *P-lower* approximation [2] of a set can now be defined as

$$\underline{PX}=\{x \mid [x]_P\subseteq X\}. \quad (4)$$

Let P and Q be equivalence relations over U, then the positive region [3] can be defined as

$$POS_P(Q) = \bigcup_{X \in U/Q} \underline{P}X \ . \tag{5}$$

Let $C \subseteq A$, $D \subseteq A$, $B \subset C$ and $C \cap D = \Phi$; if $POS_B(D) = POS_C(D)$, B is a reduction of C. The set intersection of all reductions of C is called the core of C denoted as $Core_D(C)$.

Given information system, if $A=C \cup D$, $C \cap D = \Phi$, C is the conditional attributes set and D is decision attributes set, the information system is called decision table [4].

Discernibility Matrix. Let $DT=(U, C \cup D, A, f)$ be a decision table. By $M(DT)$ we denote an $n*n$ matrix(c_{ij}), called the discernibility matrix of DT, such that:

$$c_{ij} = \begin{cases} \{\alpha \mid \alpha \in C \wedge (f_\alpha(x_i) \neq f_\alpha(x_j))\}, & f_D(x_i) \neq f_D(x_j), \\ \phi, & f_D(x_i) \neq f_D(x_j) \wedge f_C(x_i) = f_C(x_j), \\ -, & f_D(x_i) = f_D(x_j). \end{cases} \tag{6}$$

Since $M(DT)$ are symmetric and $c_{ii} = \Phi$, for $i=1,2,\ldots,n$, we represent $M(DT)$ only by elements in the lower triangle of $M(DT)$, respectively, i. e., The c_{ij}'s with $1 \leq j < i \leq n$.

Using discernibility matrix, Skowron and Rauszer [4] have proven several properties and constructed efficient algorithms related to information systems and decision tables, e.g. The set of all indispensable attributes in C is called the core of DT, denoted by $CORE_c(D)$. $CORE_c(D)$ can be characterized by $M(DT)$ in the following way:

$$CORE_C(D) = \{a \mid (a \in C) \wedge (\exists c_{ij}, ((c_{ij} \in M_{n \times n}) \wedge (c_{ij} = \{a\})))\} \ . \tag{7}$$

Reduction of the decision table

Reduction of the decision table is to delete redundant attributes in the system keeping the classification capability of the original systems or decision tables. The reducted decision table has the same function as before. Therefore reduction of the decision table is very important in practical applications.

Algorithm1 [4] is based on the discernibility matrix of the decision table.

Algorithm 1:

Input: Decision table $DT=(U, C \cup D, A, f)$.

Output: A relative reduction of decision attributes D relative to conditional attribute C.

Step 1 Compute the discernibility matrix $M_{n \times n}(DT)$ of decision table DT;

Step 2 Compute the core $CORE_C(D)$ of C relative to D;

Step 3 $\forall c_{ij}$, $i,j=1,2,\ldots,n$, if $c_{ij} \cap CORE_C(D) \neq \varnothing$, then $c_{ij} = \varnothing$;

Step 4 For all the elements c_{ij} $(c_{ij} = \varnothing)$ whose value is non-empty set in the current discernibility matrix, establish the corresponding disjunction L_{ij}, and $L_{ij} = \bigvee_{a_{l_k} \in c_{ij}} a_{l_k}$;

Step5 Conjugate all the disjunctions, then get a conjunction normal form L, $L = \bigwedge_{c_{ij} \neq \phi} L_{ij}$;

Step 6 Convert the Conjunctive L to disjunctive, then get $L = \bigvee_k L_k$;

Step 7 Output $L' = \bigvee_k (L_k \wedge L_{CORE_D(C)})$ in which $L_{CORE_D(C)} = \bigwedge_{a_{l_k} \in CORE_D(C)} a_{l_k}$, each conjunctive term $L_k \wedge L_{CORE_D(C)}$ in the disjunctive is correspond to a relative reduct of difference variable of the decision table, attributes in each $L_k \wedge L_{CORE_D(C)}$ form the relative reduction of the decision table.

After attribute reduction each record in the decision table could be used as a rule, meanwhile there are many redundant information. In other words, after reduction, not each attribute value in each record has some effect on decision rules in the information system. Therefore we must continue to reduct the results of attribute reduction. The process of excluding redundant information from the reducted

decision table is attribute value reduction. The value reduction of a given system *T* may be based on core value.The algorithm is shown as following:

Algorithm 2 [5]:

Input: An information system T.

Ouput: value reduction of T.

Step 1: Check the conditional attribute in the information system column by column. If there are conflict records after the column is deleted,then retain the original attribute value of the conflict records;else if there are duplicate records,then change its attribute value into "*";for other records, change its attribute value into "?".

Step 2: Delete the records that may produce duplicate and check each record labeled "?".If the decision could be made only by the unlabeled attribute value, then change "?" into "*", else change "?" into the original attribute value;

Step 3: Delete the entire conditional attribute labeled "*" and the records that may produce duplicate.

Step 4:If only one conditional attribute value in two records is different and one attribute of them is labeled "*",then for the record, if decision could be made by the unlabeled attribute value then delete another record,else delete the record.

Customer division based on rough set

Rough set theory provides techniques to reduce knowledge in databases. As a result of the reduction of knowledge, a set of concise and meaningful rules is produced.Therefore it provides theoretical support for customer classification prediction model based on rough set.RFM analysis refers to gather customer purchase behavior by collecting the "last purchase (Recency)", "purchase frequency (Frequency)" and "purchase amount (Monetary)" to guide marketing behavior, and then mining factor in buying behavior differences and predicting purchase preferences. In the data selection, RFM analysis method provides a direction guide for the feature selection model of customer.

In this paper, a marketing data mart is constructed and isolates the business data and analysis data based on the customer and transaction of a large supermarket. Based on the data mart, using data mining technology, the description model and predictive model of customer classification were constructed. Figure 1 is the system architecture of customer classification model; The system consists of three parts. The first part is the supermarket customer and transaction data, it provides original data for the model; The second part will process the data of the first layer, load the data to data mart focusing on customer data, then on the basis of data mart, with technology as the core of data mining based on RS, store the analysis of the results in the classification model library, The third part predicts classification for new customers through the model library. The following data mining steps are based on RS: (1) Data pretreatment (2) Attribute selection with reduction algorithm (3) Generating rules.

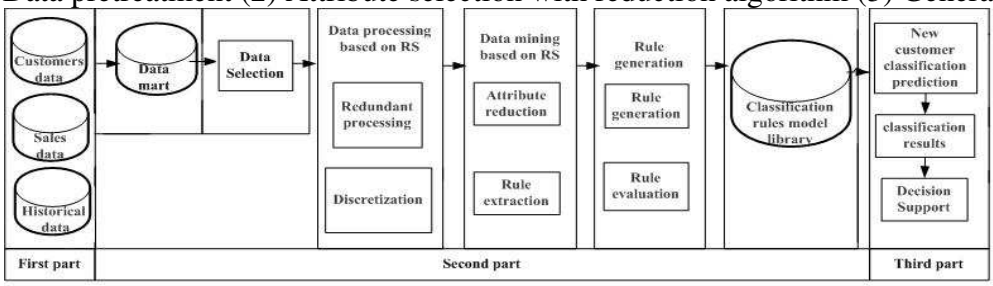

Fig. 1. The structure system of customer classification model based on Rough Set

According to the customer data in the database and sales data, one of 15 customer historical data is selected as test data sets through data cleaning. Extracting from the sale records of 3 months sale data from the preliminary statistics and the transaction records, the purchase time, purchase frequency and purchase amount of the 15 customers within three months is analyzed. Through the preliminary data

filtration of the attribute in the customer data, some customer attributes which are obviously irrelevant to division such as name, home address, telephone etc.are removed. The data will be expressed as the form of decision table in which the clustering of 8 customer attributes are conditional attributes, clustering analysis by customer categories are decision attributes. After discretization of decision table with NS discretization method, the results of the customer attribute discretization are obtained, as shown in Table 1.

Table 1. Results of the customer attribute discretization

Symbol	Meaning	Discrete value			
		0	1	2	3
A	Gender	Female	Male		
B	Marriage	Unmarried	married		
C	Area	Shahekou District	Xigang District	Ganjingzi District	ZhongshanDistrict
D	Annual income	Low	Middle	High	
E	Has Car or not	No	Yes		
F	Days from the last purchase to now	30-50	15-30	0-15	
G	Purchase frequency (times per month)	0-1	1-3	More than 3	
H	Purchase amount (yuan per time)	Less than 150	150-300	More than 300	
I	Decision attributes	Ordinary customers	Gold customers	Platinum customers	

After the sale records of Customer are converted, the decision table is shown in Table 2.

Table 2. Decision table after conversion

No	A	B	C	D	E	F	G	H	I
1	0	0	2	1	0	2	0	1	1
2	0	0	1	2	0	2	1	2	2
3	0	0	2	1	0	0	0	1	0
4	0	1	0	0	0	1	0	1	1
5	1	1	0	0	0	0	0	0	0
6	0	1	0	1	0	1	1	0	0
7	1	0	0	1	0	2	2	2	2
8	1	0	3	1	0	2	2	1	1
9	0	1	0	0	0	1	1	1	0
10	1	0	1	2	0	2	2	2	2
11	1	0	0	1	1	2	1	2	1
12	0	1	0	1	1	1	1	1	1
13	0	1	0	1	0	0	0	0	0
14	0	0	2	1	0	0	0	1	0
15	0	1	0	0	0	1	0	2	2

After being reduced with algorithm 1,the results of the reduction are $\{D,F,G,H\},\{E,F,G,H\}$. The results show the importance of three attributes that are days from the last purchase to now, purchase frequency and purchase amount.It coincides with the theory of marketing RFM analysis method. Continue to deduct the results $\{D,F,G,H\}$ for attribute value reduction with algorithm 2, the reduction rules is shown in Table 3.

Table 3. Rules extracted from {*D*,*F*,*G*,*H*}

Rule no	Record no	D	F	G	H	I	Rule no	Record no	D	F	G	H	I
1	1	*	2	0	1	1	19	7,10	*	2	2	2	2
2	1,8	1	2	*	1	1	20	7	1	*	2	2	2
3	1	1	2	0	*	1	21	8	*	2	2	1	1
4	2	2	*	1	2	2	22	8	1	*	2	1	1
5	2,10	2	2	*	2	2	23	9	*	1	1	1	0
6	2	2	2	1	*	2	24	9	0	*	1	1	0
7	3,14	*	0	0	1	0	25	9	0	1	1	*	0
8	3,14	1	0	*	1	0	26	10	2	*	2	2	2
9	3,13,14	1	0	0	*	0	27	10	2	2	2	*	2
10	4	*	1	0	1	1	28	11	*	2	1	2	1
11	4	0	*	0	1	1	29	11	1	2	1	*	1
12	5,13	*	0	0	0	0	30	12	1	*	1	1	1
13	5	0	*	0	0	0	31	12	1	1	*	1	1
14	5	0	0	*	0	0	32	13	1	*	0	0	0
15	5	0	0	0	*	0	33	13	1	0	*	0	0
16	6	*	1	1	0	0	34	15	*	1	0	2	2
17	6	1	*	1	0	0	35	15	0	*	0	2	2
18	6	1	1	*	0	0	36	15	0	1	*	2	2

The records in the table reflect the original information of decision rules in the table, rule 1 can be summarized as:

Rule 1: if（F，2）and（G，0）and（H，1）then I=1.

For the customer, if his days from the last purchase to now is 15, purchase frequency is 0-1 times per month, the amount of each purchase is 0-150 yuan, he is the ordinary customer.

This example can also select the condition attribute {E, F, G, H} as the reduction result of condition attribute, the results obtained may be different with {D, F, G, H}.Therefore, the different classification criteria leads to different extraction rule set. The classification rules could be stored into the knowledge database to provide a basis for the new object classification prediction and decision analysis.

Summary

In this paper, a customer classification model was designed based on rough set theory and supermarket customers were analyzed with the algorithm of rough sets reduction and decision rule. By removing redundant attributes and eliminating excessive rules, rules that affect customer classification from the customer information were obtained for business decision-making. Examples show that it has good practicability.

A K-nearest-neighbour Based Classifier for Securities Text Categorization

TIEBIN LIU

University of Chinese Academy of Sciencesm, China Futures Association

liutiebin@cfachina.org

Keywords: Text categorization; KNN; VSM; event driven; information securities investment.

Abstract. Event-driven investments have gained great importance and popularity. Due to the importance of the timely and effective messages for successful investment, the automated categorization of documents into predefined labels has received an ever-increased attention in the recent years. This paper implements a new text document classifier by integrating the K-nearest neighbour (KNN) classification approach with the VSM vector space model. By screening the feature items and weighted key items, the proposed classifier turns the financial information text into N-dimensional vector and identified the positive and negative information, furthermore achieve to the classification optimized. In addition, the classification model constructed by the proposed algorithm can be updated incrementally, and it has great scalability in event-driven securities investment for investors.

Introduction

In examining China recent securities research, the event driven investments have attracted a major attention of global securities investment researchers in various fields. By using the logical and quantitative analysis, the event driven investment has gained great importance and popularity. In particular, there are three mainstream investment patterns: developed investment theme model and the traditional value investment, trends investment.

In recent years, text categorization techniques have drawn great attention and been widely used in securities research. There are a wide range of supervised learning algorithms has been applied to the documents classification, such as K-Nearest Neighbor (KNN)[1], Centroid-Based Classifier (CB)[2], Naive Bayes[3], Decision Trees[4], and Support Vector Machines (SVM)[5]. Among all these algorithms, KNN is a simple but effective method for text categorization. KNN does not build the classification model since it is a lazy learning method. As a result, it is not suited in many applications well.

With the development of the Internet, information explosion in this electronically networked world, it is more important for investor to organize securities data effectively and efficiently. In this paper, we use the vertical field of semantic analysis method to classify the securities information into subjective and objective information for the event-driven investment strategy.

The rest of this paper is organized as follows: Section 2 describes the well-known classifiers. Section 3 presents the analysis of the KNN fuzzy classifier. Related work is discussed in Section4. The paper is concluded in Section 5.

Text vector representation model

2.1 Vector Space Model

Computer can only handle binary data, the unstructured or semi-structured Chinese text are not being used directly for training or classification. The Chinese text must be represented as some specify model for the computer use. By using the vector space model[6], we constructed text vector before classification.

2.2 Select feature items

As a strong computability and maneuverability, vector space model is based on the bag of word method. Considering the series of feature items is independent, vector space model do not consider

the sequence feature items that appear in the text. According to the characteristics of Chinese words, the words library should be pretreatment to remove tabs, labels, and other no meaning words before segmentation.

2.3 Screen feature items

After the text classification systems, text feature items are still at high dimension. The text collections contain thousands of feature words, but each text contains characteristics rarely. Vector space model, in a high-dimensional sparse matrix, will affect the time complexity and space complexity for the classification algorithm. Experiments show that when the characteristic dimension of the vector space reaches a certain value can achieve very high classification performance, with the increase of feature dimensions, but will drop the classification performance. Therefore, the feature items must be effective screening.

By using the χ^2 statistical methods, we can measure the degree of correlation between the terms and the document class c. Assume that between t and c there is a one degree of χ^2 distribution. N denotes document in training corpus, c denotes a special category, t is a special term. A denotes the numbers of document belongs to c and includes t, B denotes the numbers of document do not belong to c but includes t, C denotes the numbers of document belongs to c but without t, D denotes the numbers of document do not belong to *c* and without *t*, the χ^2 value can be calculated as follows:

$$\chi^2(t,c)=\frac{N\times(AD-CD)}{(A+C)(B+D)(A+B)(C+D)} \tag{1}$$

For multi-class problem, χ^2 values were calculated for each category, and *t* can be calculated for the entire training set as the following:

$$\chi^2_{\max}(t)=\max_{i=1}^{m}\chi^2(t,c_i) \tag{2}$$

$$\chi^2_{\arg}(t)=\sum_{j=1}^{k}P(c_j)\chi^2(t,c_j) \tag{3}$$

where *m* is the number of categories. Sort the original feature space by CHI value, and retain the first *N* terms as the feature documentation. Where, *N* can be obtained by the experimental results.

2.4 Keywords Library

Most majority media will appear some positive subjective terms, such as, optimistic, buy, optimistic, support, up. The negative subjective terms often appears: not optimistic, sell, resistance, pessimistic, down. After collection, we obtained a library of financial subjective Keywords, where positive subjective category lexicon: PkeyWords, negative subjective category lexicon: N key Words. By weight the feature KeyWords, we can effectively improve the classification accuracy.

2.5 N-dimensional text vector

In the vector space model for an item with n text characteristic $d(t_1,t_2,\cdots,t_n)$, the text can be represented as $d=((t_1,W_1),(t_2,W_2),\cdots,(t_n,W_n))$, and $d=(W_1,W_2,\cdots,W_n)$ for short. Where t_i denotes the $i(i=1,\ldots,n)$ characteristic item, W_i is the weights value for the $i(i=1,\ldots,n)$ feature in the text. By the Boolean weight calculation method, set feature items value to 1 for all TF> 0 (Term Frequency), and the value of all the positive words right word library is set to 2, the word weights negative keyword library is set to -2.

$$W_i=\begin{cases}-2 & (If>0\,and\quad t_i\in NKeyWords)\\ 2 & (If>0\,and\quad t_i\in PKeyWords)\\ 1 & (If>0\,and\quad t_i\notin KeyWords)\\ 0 & (If=0)\end{cases} \tag{4}$$

We can use Fig. 1 to represent the process of a Chinese text into text vector, and Fig. 2 to illustrate the vector space model under the text representation.

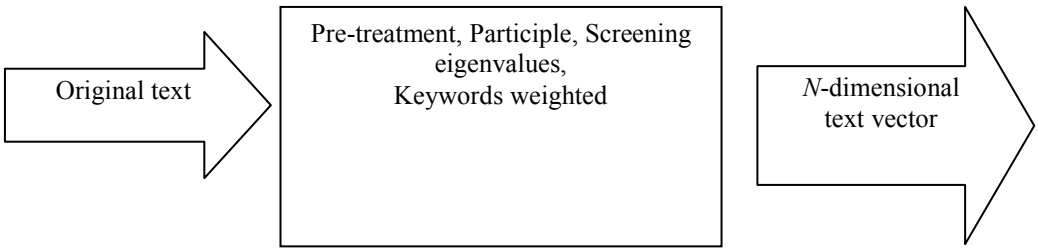

Fig. 1 Text converted to N-dimensional vector

	t_1	t_2	t_3	…	…	t_n

KNN fuzzy classifier

It is important to construct a classification function or classifier for the automatic text classification. Training methods and classification algorithm is the core of the classification. There are a wide range of supervised learning algorithms has been applied to the documents classification, such as support vector machine algorithm, neural network method, the average maximum entropy method, a recent K neighbor method and the Bayesian method, we use KNN classification algorithm for text classification learning[7,8].

3.1 KNN classifier

To classify an unknown document, the KNN classifier ranks the document's neighbors among the training documents, and use the class labels of k most similarity neighbors to predict the class of the input document. As a statistical method, the KNN classification approach has been widely used in various types of classification tasks, especially in pattern recognition. Throughout this paper, we use Euclidean distance for calculation.

3.2 KNN algorithm

The process of the KNN classifier is as follows: given a test document x , find K nearest neighbors of x among training documents, and score category candidates for x based on the categories of K neighbors. To measure the similarity efficiently, we make use of the Euclidean distance as follows [9]:

1) By using feature items, describe a collection of re-training text vector
2) According to the characteristics of the new text word segmentation, identify a new text vector representation.
3) By using the following formula, Select text for the most similar to the training text K

$$Sim\left(d_i, d_j\right) = \frac{\sum_{k=1}^{M} W_{ik} \times W_{jk}}{\sqrt{\left(\sum_{k=1}^{M} W_{ik}^2\right)\left(\sum_{k=1}^{M} W_{jk}^2\right)}} \quad (5)$$

For a given initial K, we could adjust the K value by the results of experimental tests.

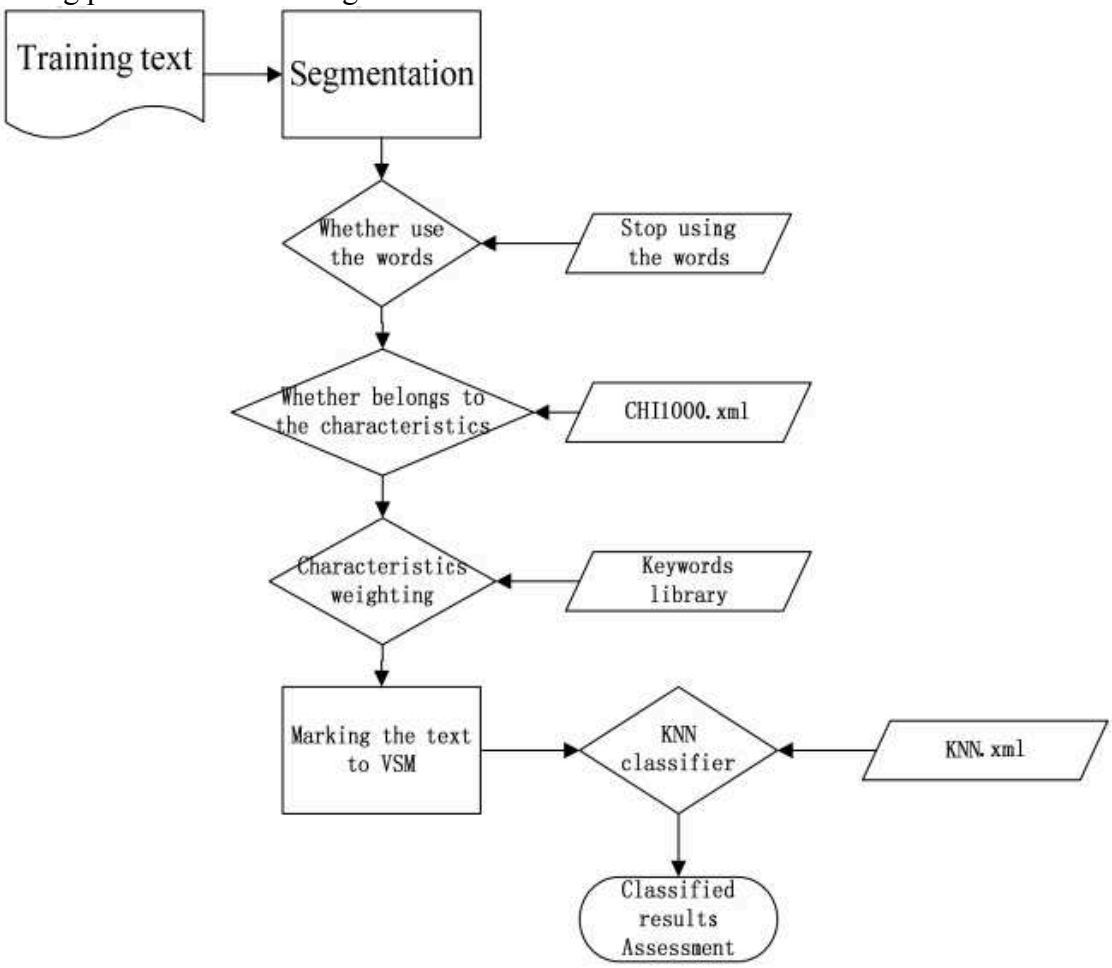
In the new text K neighbors, calculate the weight as follows:

$$p\left(\vec{x}, c_j\right) = \sum_{\partial, eKNN} Sim\left(\vec{x}, \vec{d_i}\right) y\left(\vec{d_i}, c_j\right) \quad (6)$$

Where x is the new text feature vector, $Sim\left(\vec{x}, \vec{d_1}\right)$ is the same step, and $y\left(\vec{d_i}, c_j\right)$ is a function of class attributes, i.e. if $\vec{d_i}$ belong to the class c_j , then the function value is 1, otherwise 0.

Assign the text to the largest category.

Test training process shown in Fig. 3:



Test Results

4.1 Experiment design

Purpose: Verify suitable dimension for the corpus.

Experimental environment: The experimental data consisted of financial news from the financial website (Hexun, Eastern Wealth), category information 1000, the average of each 800 words, the time span of three months. Feature dimensions were taken 50, 100, 200, 500, 1000, 2000, 3000 respectively. Throughout our experiments, algorithms are coded in JAVA and running on a Pentium-4 machine with single 2.0 GHz CPU.

Results: By using the different feature dimension values, calculate the accuracy, recall and F1 value. Classification results in the keyword feature items weighted KNN classifier as Table 1 and Fig. 4.

Table 1 Different feature dimension classification results

Feature dimensions	Accuracy	recall	F1 value
50	54.77	51	52.82
100	61.89	58.71	60.26
200	68.21	65.1	66.62
500	75.5	72.39	73.91
1000	86.29	83.89	85.07
2000	70.66	67.32	68.95
3000	65.57	61.19	63.3

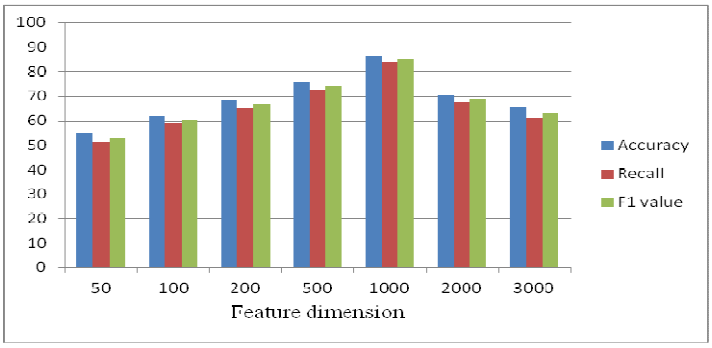


Fig. 4 Different feature dimension classification results

As can be seen from the table 1 and figure 4 above, feature selection function for the dimension of selected feature items have a significant effect on the classification results. When the parameters characteristic dimension choose their values in the interval $[50,100]$, each evaluation index is increased. When the parameters characteristic dimension choose their values in the interval $[1000,3000]$, the classification of the effect is gradually decreased. Furthermore, the highest value is 1000. Therefore, we obtained: the feature dimension is not as high as possible, but if the feature dimension is too small, then it is likely to ignore some contribution to the feature items classification. Therefore, each set has an optimal training text characteristics dimension through experiments. In this paper, we use the 1000 feature dimension.

4.2 Experiment II

Purpose: Find the weighted keyword feature items of financial information on the impact of class text classification.

Experimental environment: The experimental data consisted of financial news from the financial website (Hexun, Eastern wealth), category information 1000, the average of each 800 words, the time span of three months. By the Securities analyst experience, we classified the samples to 3 categories: positive subjective category, the negative category and objective categories. Where positive type text is 405, negative type text is 288, objective type text is 307, and feature items dimension is 1000. Throughout our experiments, algorithms are coded in JAVA and running on a Pentium-4 machine with single 2.0 GHz CPU.

Results: By analysis keyword feature items with or without weighted KNN classifier, the accuracy rate, recall and F1 value are calculated for the KNN classifiers. Results shown in Table 2 and Fig. 5

As can be seen from the table 2 and fig. 5 above, the results of weighted keyword feature items on the classification has a significant impact, but the accuracy of without weighted keyword classification is only about 60%, which does not satisfy the requirements of the financial event analysis. After a weighted optimization, accuracy for weighted keyword feature items has greatly improved to more than 85%, which basically satisfy the classification for positive and negative effects on the financial events analysis.

Table 2 Keyword feature items with and without weighted KNN

Classifier	Accuracy	Recall	F1 value
Feature items without weighted KNN	62.56	60.83	61.08
Feature items weighted KNN	86.29	85.87	86.08
Artificial classifier	100	100	100

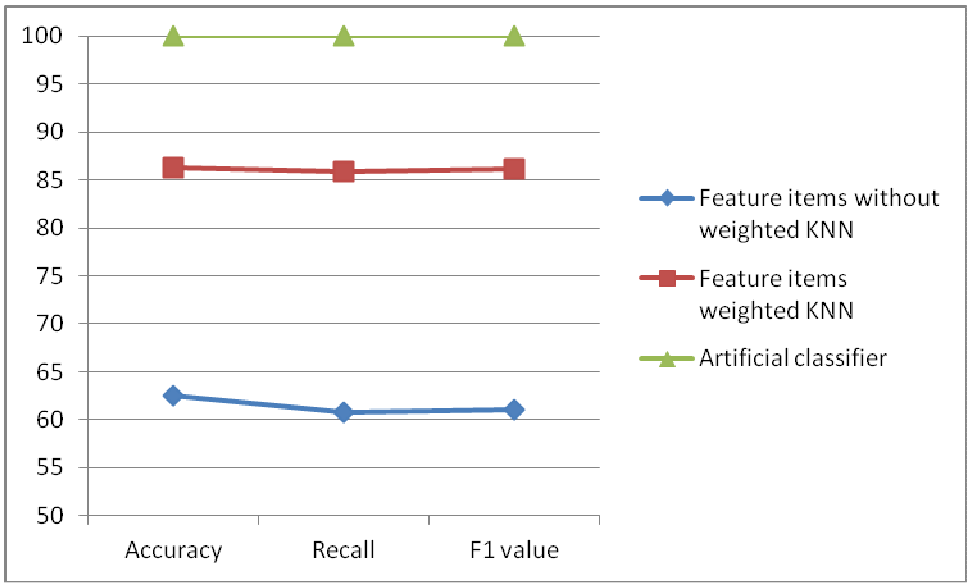

Fig. 5 Keyword feature items with or without weighted KNN

Conclusions

In this paper, we propose a generalized cluster centroid based classifier for text categorization by utilizing a constrained clustering algorithm to integrate KNN and VSM. Unlike the conventional KNN classification approach, the VSM-KNN approach is reported to have low impact on the implementation of parameter. The classification accuracy of the VSM-KNN approach is relatively consistent with the implementation of different values of parameter, as compared to the conventional KNN approach, which its classification accuracy is severely degraded if inappropriate values of parameter are implemented to the classifier. The financial information system can classify the positive or negative news with accuracy of 85%, which improve the accuracy rate of 25% than before optimization model. We can use the method we proposed to provide timely event-driven investments reference for the stock market investors.

Research of Intelligent Warehouse Layout Base on Genetic Algorithm and Dynamic Programming

Yang Lvqing, Yan Qiang

Software School of Xiamen University, Xiamen, China
lqyang@xmu.edu.cn, klt_15@qq.com

Keywords: Warehouse Layout; Genetic Algorithm; Dynamic Programming

Abstract. Intelligent warehouse management can effectively improve the work efficiency and decreasing operating costs for a company, and the reasonableness of warehouse layout has played a very important role in it. This paper will aim at the warehouse layout problem, analyze the superiority of genetic algorithm and dynamic programming for the problem, and base on the genetic algorithm, integrating the thoughts of dynamic programming to put forward an optimization strategy. It can improve the accuracy and efficiency of genetic algorithm by a modified encoding scheme and fitness function, in order to put forward a more optimal scheme of warehouse layout, provide the information base for following operation of warehouse management, and improve the intelligent level of warehouse management system.

Introduction

With the continuous development of modern technology, the intelligent warehouse management which using the information technology becomes the focus of attention. The intelligent warehouse management can take advantage of existing resources sufficiently, it make the planning, inspection and control of the warehouse and its goods will become more precise and more efficient, it improve the accuracy of warehouse management and dispatch, and it reduce the cost of operation and maintenance. In the actual process of warehouse management, the reasonableness of warehouse layout is always the basis of the work. Firstly, warehouse layout determines the usage of the warehouse, it is the key of improve the utilization rate of the warehouse and reduce the cost of warehouse management. Secondly, warehouse layout distributes the space of all kinds of goods, it will influence work efficiency of portage and placement. Thirdly, warehouse layout can directly reflect the situation of warehouse and provide information and support to the warehouse manager. Therefore, the reasonableness of warehouse layout played a major role in intelligent warehouse management. This page will base on dynamic programming and genetic algorithm, put forward an optimization strategy to the warehouse layout problem.

Overview of the warehouse layout problem

In the traditional warehouse management and operation, the location of goods always bases on a rough classification, standard of the company or habit of the operator. This operation will largely waste the space of the warehouse, and reduce the work efficiency. Therefore, using intelligent warehouse management and optimal strategy to solve the problem of warehouse layout will drastically decrease the amount of time in handling and stacking of goods, and increase the work efficiency.

In order to convenient to discuss, this page will assume the warehouse like this:

The warehouse is a rectangle, and the entrance in a single direction with an unlimited size. There are several rows of shelves in the warehouse. Each shelf is divided into unit of the same size, and the goods are stored in the unit. Galleries are between the shelves. As showed in the figure 1:

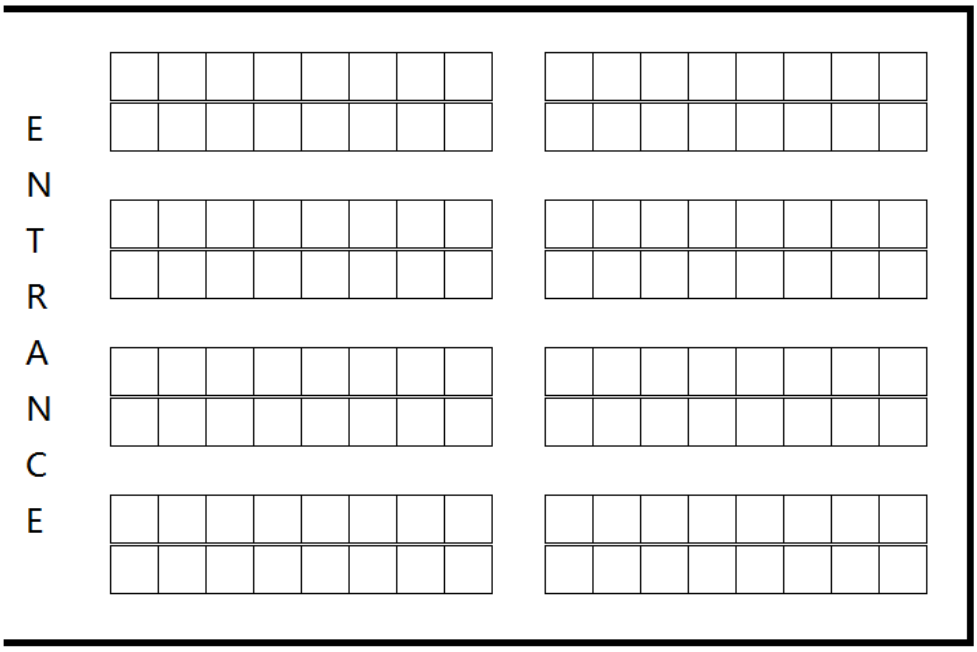

Fig.1 Warehouse structure diagram

Optimization of Warehouse layout base on Genetic Algorithm and Dynamic Programming

Genetic Algorithm is a random search method which is imitated the evolution of biology. It can solve the extremum problem effectively. Compare with traditional algorithm, genetic algorithm has a distinct advantage because it needs not an expression or a function so that it will not be limited by derivation or continuity of function and it can solve all of the practical problems steadily. At the warehouse layout problem, it need find the optimal solution of a large number of layout schemes, and it can't be solved by an exact expression, so genetic algorithm is a well choice to solve the problem.

Dynamic programming is a thought which divided the problem into several subproblem and solves the problem base on solving the subproblem, and record the result of subproblem in order to solve the same subproblem faster. For the warehouse layout problem, it has lots of the same subproblems when it evaluates the fitness of a chromosome. Therefore, dynamic programming will make the genetic algorithm more efficient.

The optimizing strategy of this paper proposed is based on the genetic algorithm, therefore, following page will accord with the steps of the genetic algorithm to solve the problem, that is encoding, determining fitness function, population initialization, population evolution and finding an optimal solution.

Encoding. Encoding is the first step in the genetic algorithm, it also determines the direction to solve the problem next step.

This page use the coding scheme base on choose shelves of goods, for a batch of the incoming goods, the numbers of shelves of each goods selected link into chromosome code of this scheme, the length of the code corresponds to the quantity of the goods, genes corresponds to each of goods, the value of genes corresponds to the shelves of each of goods selected. In addition, different sequence of goods in one shelf will link into a same chromosome code, this problem will be explained in the following paragraphs.

Fitness function. Fitness function is the key to evaluation of a chromosome code in genetic algorithm. It determines the probability of inheritance and influences the optimality of the genetic algorithm.

This page will base on the time needed when the good stock out and the stock out frequency of the good to build the fitness function. That means putting the good which has a high frequency near

by the entrance will improve the fitness of this scheme. The fitness function is express by following function:

$$f(x) = k\sum_{i=1}^{n}[u_i(T_{max} - t_i)] + C_{min} \quad (1)$$

For the question of the same code in one shelf, use dynamic planning to find the optimal solution in a shelf is a well choice. It not only can solve the problem in current scheme, but also can record the result of subproblem which will be calculated several times. It can improve the efficiency of genetic algorithm.

Population initialization. Genetic algorithm needs an initial population to start the simulation of evolution. According to population size M, quantity of goods n, quantity of shelves m, builds M chromosome sequences by n genes between 0 and m-1 as the initial population. Population size M will be determined by the actual situation, generally can be set to 500. In addition, in order to improve the efficiency of genetic algorithm, we will exclude the scheme that all the goods put into a same shelf.

Population evolution. Genetic algorithm simulate the population evolution in following 3 operations: Firstly, every chromosome will be selected by probability, the chromosome with high fitness will be selected and the chromosomes with a low fitness may be eliminated. This operation will keep the high fitness of population and the correctness of the genetic algorithm. Secondly, exchange part of the gene between two chromosomes. This operation is an important way to find a chromosome with a higher fitness. Thirdly, change part of gene of a chromosome. This operation can increase the search scope and ability of the genetic algorithm.

Optimal solution. When the quantity of population to the desire, genetic algorithm will stop and find the optimal chromosome from every population.

Realization of the software system

In the intelligent warehouse management system, algorithm will realize and apply with following steps:

When a batch of goods have arrived at the warehouse, the administrator of warehouse will scan every goods by the RFID device, and add the information of goods or gain from the database, like length, width, height, weight.

Gain the information and state of the warehouse from the database, like the quantity of the shelves, the occupancy of every shelf, status of every unit.

In the population initialization and population evolution, system will combine the information which is gained before to analyze the feasibility of the current layout, and it will get rid of the illegal solution to improve the efficiency of genetic algorithm.

Gain the statistical information like the frequency of goods stock in and stock out, confirm and correct the fitness function, that make the assessment more accurately.

According to the actual conditions, set an appropriate termination condition of population evolution to satisfy the requirement of time and precision. After it concluded the optimal solution, system begins the operation of goods stock in and updates the layout status to the database.

Summary

Warehouse layout problem is an important part of intelligent warehouse management. This page put forward an optimization strategy of warehouse layout problem. On the basis of the genetic algorithm, combine the thoughts of dynamic programming to optimize the fitness function. It can improve the accuracy and efficiency of genetic algorithm, provide a better warehouse layout solution, increase the work efficiency and space utilization rate of warehouse, and provide information to following warehouse operation. At the same time, this solution can conclude the optimal solution in a large probability, but every algorithm has limitation, especially to solve the problem which is changeable. Therefore, in the process of solving the warehouse layout problem, we can blend other intelligent algorithm in it, it also a worthy research direction in the future.

Keywords: Difference degree; Attributes significance; Information system

Abstract. Currently, rough set theory has been widely used in many fields. In rough set theory, how to measure the attributes significance of the data is a core content. In order to solve the problem that the existing attributes significance measure methods usually ignore the interaction among the attributes, the paper presents a measure method based on difference degree. When given a set, the proposed method first divides it into several subsets according to the value of condition attributes, and then computes the difference degree in the subsets. Secondly, the important attributes are selected based on the value of difference degree. Further the paper discussed some properties of the difference degree, and the experimental results shows the effectiveness of this method in the final.

Introduction

In general, the information in the data sets is stored for different learning and mining tasks. Therefore, for a specific data analysis tasks, attributes in the information system are not equally important, it may also exist redundant or irrelevant information. An excessive amount of attributes storing in the data set may cause a significant slowdown in the learning process and deteriorate the performance of learning algorithm. Therefore, how to extract useful knowledge effectively has become a critical issue for the area such as systematic science and information science.

As a soft science computing tool, rough set theory [1] can be used to deal with uncertainty information, and it provides a mathematical framework to discover attributes significance and reduce the number of attributes contained in a dataset. Now, it has been successfully applied to machine learning, decision analysis, process control, and other fields, and caused widespread concern in the academic community. Aiming at the problem of attribute significance measurement, many scholars have carried on a discussion from different views (for example,Komorowski et al.[2] introduced an algorithm by constructing a kind of discernibility function from the data set and simplify it to measure the attributes significance. Skowron [3] proposed an algorithm basing on discernibility matrix to carry out the attributes significance), however, these algorithms have obvious shortcomings: Firstly, when the objects of the universe and attributes are on a larger scale, it requires a lot of computing time; Secondly, it has been proved that the problem of finding the minimal reduction is NP-hard, so when the data sets are on a large scale, it does not have a maneuverability. For the deficiency of [2, 3], a lot of heuristic algorithms have been developed.

According to the measures of attributes significance, the existing heuristic algorithms mainly include the following two categories: (I) Positive region-based methods. Hu et al. [4] gave an extension of these positive region methods for heterogeneous feature selection based on neighborhood rough set model. However, the corresponding algorithms ignore the additional computation required for selecting significant attributes. (II) Entropy-based methods. Wu [5] put forward an algorithm to measure the attribute significance based on information entropy. The studies can greatly decrease search space that the information system requires.

It should be noted that, the above formulas of attribute significance measure methods in heuristic algorithms can be represented in a unified form. They are used to select an attribute by heuristic algorithm. But this heuristic information may not find the optimal solution in a given information system. Since in practical problems, the attributes in system are not independent, but interacted to other degree. For some attributes, the significance of the individual attribute may be small, but once

integrated, they can have a big impact on the classification in system. However the measures of single attribute significance do not take into account of the interaction among the attributes. As the heuristic algorithms may select the attribute with a big value of significance, the one with a small value may not be selected.

From the perspective of partition on the information system, this paper put forward a generalized measure method of attributes significance. Since in practical applications, the difference degree among attributes may be a linear measurement mode, and also be a kind of nonlinear measurement mode, so for specific describing these problems, this paper proposed the concept of difference degree. For one attribute subset, if the difference degree is very small, which means there is little difference between it and all the attributes in partition, then the subset is important for the information system. This measure method can not only reflect the importance of a single attribute, but also can reflect the comprehensive significance of the attribute combination. In order to prove the feasibility and validity, in this paper, we make a comparison between the inclusion degree method and the proposed generalized attributes significance measure method.

Preliminaries

In this paper, the information system is referred to (U, A, F_A). Where U is a non-empty finite set of research subjects (called the universe), A is non-empty finite set of attributes; $V(a)$ is the range of attribute a, $F_A=\{f_a: U\to V(a) \mid a\in A\}$ is the information function. For $B\subset A$, $R_B=\{(x, y)\in U\times U \mid f_a(x)=f_a(y), a\in B\}$ denotes the equivalence relation on U with respect to B (where $f_a(x)$ denotes the value of object x on attribute a); U/R_B (U/B for short) denotes the partition on U formed by the equivalence class of R_B (that is, $U/B=\{[x]_B \mid x\in U\}$), $[x]_B=\{y \mid (x, y)\in R_B\}$ denotes the R_B equivalence class of x). If U/B is interpreted as a kind of knowledge base, then each equivalence class $[x]_B$ can be considered as a basic knowledge particle on universe U. In this sense, rough set theory provides a method to describe the knowledge basing on equivalence relation.

For any $P\subset Q\subset A$, $[x]_P\subset[x]_Q$ are true for any $x\in U$, that is, U/Q is finer than U/P ($U/Q\prec U/P$ for short). Thus, in the information system (U, A, F_A), the size of attribute subset P determines the knowledge granularity of knowledge base U/P to some degree, the bigger the size of P, the more powerful the description ability of U/P. Therefore, how to reduce the condition attributes and get the support attributes on the basis of remaining the fundamental performances of the information system unchanged have arose the widespread attentions in the academic and application fields.

The attribute significance measure based on difference degree

In this section, we proposed a concept of difference degree and a significance measure method based on information system and difference degree. For convenience, the following use $|A|$ represents the number of elements in the finite A.

Definition 1 Let U be a non-empty finite set, $\wp(U)=\{X \mid X\subseteq U\}$, $G:\wp(U)\times\wp(U)\to[0,\infty)$, $X, Y, Z\in\wp(U)$. If $G(X, Y)$ satisfied: 1) $G(X, X)=0$; 2) when $X\subset Y\subset Z$, $G(X, Z)\geq G(Y, Z)$, then we call $G(X, Y)$ a difference degree function on U.

It is not difficult to see that, for given inclusion degree function $D(Y \mid X)$ on U (that is, for any $X, Y, Z\in\wp(U)$: 1) $0\leq D(Y \mid X)\leq 1$; 2) when $X\subset Y, D(Y \mid X)=1$; 3) when $X\subset Y\subset Z$, $D(X \mid Z)\leq D(X \mid Y)$; 4) when $X\subset Y$, $D(X \mid Z)\leq D(Y \mid Z)$), $G(X, Y)=1-D(Y \mid X)$ is a difference degree function on U. But it is worth noting that the difference degree function $G(X, Y)$ on U may not be able to export the inclusion degree function $D(Y \mid X)$ on U, for example, $G_1(X, Y)=(|X|-|Y|)^2$ and $G_2(X, Y)=|(X-Y)\cup(Y-X)|$ are the difference degree functions on U, but whether through various linear transform, $G_1(X, Y)$ and $G_2(X, Y)$ cannot be converted into the inclusion degree function on U. This shows that the difference degree and the inclusion degree are different in essence on U.

Definition 2 Let (U, A, F_A) be an information system, $P \subset A, U/P = \{[x]_P | x \in U\}$, $G(X, Y)$ be a difference degree function on U. Then

$$M(P | A \oplus G) = \frac{1}{|U|} \sum_{x \in U} G([x]_P, [x]_A). \quad (1)$$

is called the significance measure of the P based on information system(U, A, F_A) and the difference degree function $G(X, Y)$ (difference degree of P for short).

Formula (1) shows the difference of overall description power between U/P and U/A from the perspective of average. It reflects significance of the attribute subset P relative to the whole attributes A, the bigger the value of $M(P|A \oplus G)$, the larger the uncertainty of attribute subset P in representing A. in particular, if $M(P|A \oplus G)=0$, then the (U, P, F_P) and (U, A, F_A) have the same ability in knowledge description, which means that the comprehensive significance of attribute subset P is equal to that of the attributes set A. then from the angle of knowledge granularity to express the difference degree in information system.

From what has been discussed above, the significance of attribute subset P can be measured by

$$S(P | A \oplus G) = 1 - \frac{M(P | A \oplus G)}{\max_{P \subset A} M(P | A \oplus G)}. \quad (2)$$

Formula (2) indicated that the bigger the value of $S(P | A \oplus G)$, the more significance of attribute subset P. In order to express it in a much clearer way, we describe the difference degree from the perspective of knowledge granularity in the following.

Suppose that $U/A = \{U_1^A, U_2^A, \cdots, U_m^A\}$, $U/P = \{U_1^P, U_2^P, \cdots, U_k^P\}$ are partitions induced by attribute set P and A. From $P \subset A$, and $[x]_A \subset [x]_P$ for any $x \in U$, we can obtain that

$$M(P | A \oplus G) = \sum_{i=1}^{m} \frac{|U_i^A|}{|U|} G(U_j^P (U_i^A \subset U_j^P), U_i^A). \quad (3)$$

Here, $U_j^P (U_i^A \subset U_j^P)$ denotes U_j^P which includes U_i^A. Since U/P and U/A are partitions of U, and $U/A \prec U/P$, for any given $U_i^A \in U/A$, there must be existing only one $U_j^P \in U/P$ such that $U_i^A \subset U_j^P$. This means that the implication of (3) is certain.

It can be seen from (3), the difference degree is the weighted average of the knowledge granularity difference between attribute subset P and the whole attribute set A. In the following, we will discuss the properties of difference degree in theory.

Property 1. Let (U, A, F_A) be an information system and $P \subset Q \subset A$. Then $M(P|A \oplus G) = M(Q|A \oplus G)$ for any difference degree function $G(X, Y)$ if and only $U/P = U/Q$.

Property 1 shows that if the partition induced by attribute subset P is the same as that by the whole attribute set A, then the difference degree are the same as well.

Property 2. Let (U, A, F_A) be an information system, $P \subset A$, $U/A = \{U_1^A, U_2^A, \cdots, U_m^A\}$. Then $\max_{P \subset A} M(P | A \oplus G) = \frac{1}{|U|} \sum_{i=1}^{m} |U_i^A| G(U_i^A, U)$.

Property 2 shows that, the maximum value of difference degree is achieved when the granularity of knowledge determined by P is the coarsest. Namely that, when $U/P = \{U\}$, the value of $M(P|A \oplus G)$ is maximum.

The performance analysis of difference degree

This section combines an example to further analyze the relationship and the difference between the difference degree and other measures of attributes significance in information systems.

Example 1. In the information system (U, A, F_A), U={1, 2, 3, 4, 5, 6, 7, 8, 9, 10}, A={a_1, a_2, a_3, a_4}, $P \subset A$, and U/A={{1, 2}, {3, 4}, {5}, {6, 7, 8}, {9}, {10}}. Then the significance of several attribute subsets (see Table 1) can be obtained according to the following difference degree functions: 1) $G_1(X,Y)=1-|X\bigcap Y|/|X|$; 2) $G_2(X, Y)=(|X|-|Y|)^n$.

From Table 1, it is not difficult to see that, inclusion degree is a kind of linear measurement, but the difference degree can be indicated as a linear measure or non-linear measure, it cannot be converted by inclusion degree. The bigger the value of difference degree, the less significance of the attribute subset, in addition to this, we can see that if the equivalence class of U/A were regarded as an elementary granule of knowledge, then the difference degree is the weighted average of uncertainty increment caused by combination of elementary granule. The more elementary granule of knowledge combined, the larger the difference degree is.

Table 1 The attribute significance of several different attribute subsets

P	U/P	$S(P\|A\oplus G_1)$	$S(P\|A\oplus G_2)$		
			n=0.5	n=1	n=2
$\{a_1,a_2,a_3,a_4\}$	{{1, 2}, {3, 4}, {5}, {6, 7, 8}, {9}, {10}}	1	1	1	1
$\{a_1,a_2,a_3\}$	{{1, 2}, {3, 4}, {5, 6, 7, 8}, {9}, {10}}	0.81	0.83	0.925	0.982
$\{a_1,a_2,a_4\}$	{{1, 2, 3, 4}, {5}, {6, 7, 8}, {9}, {10}}	0.75	0.80	0.9	0.975
$\{a_2,a_3,a_4\}$	{{1, 2, 3, 4}, {5, 6, 7, 8}, {9}, {10}}	0.56	0.63	0.85	0.957
$\{a_1,a_3,a_4\}$	{{1, 2}, {3, 4}, {5}, {6, 7, 8, 9}, {10}}	0.81	0.83	0.925	0.982
$\{a_1,a_3\}$	{{1, 2, 3, 4}, {5, 6, 7, 8, 9, 10}}	0.25	0.38	0.6	0.87
$\{a_2,a_3\}$	{{1, 2, 3, 4}, {5, 6, 7, 8}, {9, 10}}	0.44	0.56	0.8	0.954
$\{a_2,a_4\}$	{{1, 2, 3, 4}, {5, 6, 7, 8, 9}, {10}}	0.4	0.51	0.69	0.91

Conclusions

At present, how to measure the attributes significance of data is still a challenging issue in the area of artificial intellegence. This paper proposes a generalized measure method. Due to that the difference degree characterizes the uncertainty of the attribute subset in representing the whole attributes. It can reflect the significance of attribute subset from another perspective. And it can be seen from the example that this approach is feasibility and effectiveness when for different problems, it can provide a new way to deal with the practical application data.

Keywords: PED, stereo matching, point-cloud, potential energy, image fusion

Abstract. The paper proposes a new method that utilizes Parallel Estimation of Distribution(PED) to obtain disparity map of two images and fuses 3D point-cloud by the disparity. Estimation of Distribution（ED）has several advantages such as low complexity and high efficiency while it also has the shortcoming that it's sensitive to initial samples and the final solution is local optimum but global optimum. In order to exert its merit and overcome the shortcoming, this paper will improve the ED by parallel sampling to diminish the sensitivity with Adaptive Support-Weight method. We called it Parallel Estimation of Distribution(PED). After disparity map is obtained, the two images will be divided into high frequency and low frequency by lifting wavelet respectively and the frequency coefficient of each image will be averaged into fusion frequency. Finally, the fused frequency coefficient will be transformed by inverse lifting wavelet to the final fused image. The experiment has proved that the matching speed is outstanding without losing precision.

Introduction

Stereo matching is an aporia in computer vision and one of key technology. Recently, a lot of studies about stereo matching have been proposed[1-8]. Totally, stereo matching methods can be divided into local and global algorithm. Local algorithm[11] is mainly based on region and based on feature. Usually its goal is to find matched points of the whole image by minimizing matching cost of corresponding window. While the goal of global method is to find an energy function that is related to disparity and is optimal globally, then the disparity map can be got by minimizing the energy function. Currently, global algorithm is focused on graph cut(GC)[1-2][9] and belief propagation(BP)[3-7]. Although the effect of the two methods is outstanding, the complexity is high and efficiency is not extraordinary. So many improvements have been performed on them. GC method firstly segments images to many parts and then obtains disparity map by searching best matching region for each segmentation part. BP method is actually a dense matching that transforms matching issue to Markov Random Field(MRF) model which gets dense disparity by computing the maximum a posteriori probability based on energy function and some rule. Now the more popular method named Adaptive Support-Weight(ASW) is one efficient global method that chooses a fixed window whose center is the point to be matched and that computes matching cost which is the sum of differences of corresponding pixel in the window by setting a weight via spatial distance and CIELab distance. ASW is more precise than SSD, SAD and NND. However the searching process of ASW is one by one, its high computation and low speed are inevitable.

Evolutionary Algorithm(EA) is one of probabilistic optimization algorithms. Genetic Algorithm(GA) and Differential Evolution Algorithm(DEA) are famous in conventional EA. Due to the limitations of conventional EA, great modifications have been studied or new ideologies have been proposed in recent EA. Now, Ant Colony Optimization, Particle Swarm Optimization and Estimation of Distribution(ED) are celebrated among them. ED[12-14] can be regard as an improvement of GA in theory. In order to achieve the optimal sample, It searches the samples with high fitness to perform evolution as same as GA. The difference between them is that GA changes the property of each sample in the step of mutation and chiasma, but ED just increases the chosen probability of samples whose fitness is high by some probabilistic model and the samples with highest fitness will be considered as the optimal solution. Therefore, ED has great advantages over GA in optimization of discrete samples. Since probabilistic model and fitness function are the core

of ED, a large number of researchers have studied the probabilistic model and fitness function. Among them, ED based on Quasi-Copula[15-16] takes samples by constructing probabilistic model which can reflect the relation of multivariable based on discrete random data and produces new individuals, thus it is suitable to solve complex discrete issues. The goal of stereo matching is to find optimal matching among several samples and is not needed to modify image data, so ED is more suitable to stereo matching than GA. Nevertheless, because of the sensibility to initial samples, ED can sink into local optimum. In order to weaken the defect, the paper proposes a parallel method to improve ED.

We will combine ED with Adaptive-Weight theory to match two images by utilizing potential function difference to construct cost function. Then the lifting wavelet will be performed to fuse the two images and 3D spatial point-cloud will be built based on the disparity map. Experiment has shown that our method can reduce the searching volume and increase searching speed without losing precision.

Potential Function and Potential Energy

2.1 Potential Function

No definition can be found about potential function. Its definition is different in different subject area. It was often used to describe the relationship and constraint that can be expressed by function among image nodes in MRF early. Thus we can define a potential function to describe the relevancy of single node or multi-node. Let i be one point of image, the potential function can be defined as:

$$\Psi(i) = \frac{P(i)\ln(P(i)+1)}{\ln 2}$$

Where $P(i)$ represents the normal pixel value of some channel around the window whose center is i. In the same way, region potential function can be defined as:

$$\Psi(S) = \frac{\sum_{i\in S}^{N}\sum_{j\in chnel}^{M} P_j(i)\ln(P_j(i)+1)}{\ln 2}$$

Where N represents the total of the region, $chnnel$ is the channel set of RGB space which usually is $\{R,G,B\}$, M represents the channel totality. Region potential function describe the sum of potential energy in the region.

It is not significant for potential function to describe single node or region. It can be used to describe the relation between two nodes and potential energy difference will be defined.

2.2 Adaptive potential energy

After describing the potential function of single point or single region, the constraint of two nodes that can be points or regions of images will be defined. In stereo matching, a node is often a region, then potential energy difference of regions is defined as follow:

$$\Psi(S,S') = \frac{\sum_{i\in S, i'\in S'}^{N}\sum_{j\in chnnel}^{M} |\, P_j(i)\ln(P_j(i)+1) - P_j(i')\ln(P_j(i')+1)\,|}{\ln 2}$$

Where S,S' represent the corresponding regions of two images, i,i' are corresponding points of the regions. Because $\Psi(x)$ ranges from 0 to 1, $\Psi(S,S')$ that represents sum of energy difference of image corresponding region ranges from 0 to MN.

Yoon[10] proposed a method named ASW to compute matching cost. This method can describe similarity by setting adaptive-weight and combining Euclidean distance of CIELab color space and RGB color space of corresponding regions. We will also define matching cost by adaptive-weight and potential energy difference:

$$E(p,\bar{p}_d) = \frac{\sum_{q\in S_p, \bar{q}_d\in S_{\bar{p}_d}} w(p,q)w(\bar{p}_d,\bar{q}_d)\Psi(q,\bar{q}_d)}{\sum_{q\in S_p, \bar{q}_d\in S_{\bar{p}_d}} w(p,q)w(\bar{p}_d,\bar{q}_d)}$$

Where $\bar{p}_d, \bar{q}_d$ is corresponding points of two images and the disparity is d. $\Psi(q, \bar{q}_d)$ represents potential energy difference. $w(p,q)$ is the weight value of two points and is defined as:

$$w(p,q) = \exp(-(\frac{\Delta c_{pq}}{\gamma_c} + \frac{\Delta g_{pq}}{\gamma_p}))$$

Where Δc_{pq} and Δg_{pq} are Euclidean distance of CIELab space and RGB space. γ_c is 14 and γ_p is half of the window size.

Stereo matching based on parallel Estimation of Distribution

3.1 Estimation of Distribution

Estimation of Distribution is one of Evolution Algorithms which is aimed at achieving optimum of sufficiency function. Stereo matching is an optimization process essentially. Firstly ED selects several samples randomly according to some probability distribution model (such as Gaussian model). Then the samples with high sufficiency will be chosen on the basis of some strategy and the model will be updated based on these samples. Next we take samples newly by the updated model. After several iterations or some condition, the optimum is the individual that can be the mean of continuous samples or the one near to the mean of discrete samples. Due to the sensitivity to initial samples, its optimum can be local inevitably. In order to reduce the sensitivity, we will combine parallel sampling with parallel probability model mixture and applies it to stereo matching. On the premise of keeping precision, the efficiency is improved conspicuously.

3.2 Parallel Estimation of Distribution Algorithm

Parallel sampling means twi-sampling simultaneously. Then each sample sufficiency is computed and the samples with high sufficiency will be chosen to update probability distribution model respectively. Because of the independence of samples, it is feasible to take samples parallel. It's possible for parallel algorithm to reduce the sensitivity of initial samples and reduce the probability of local optimum.

Pixel fusion based on lifting wavelet and 3D point-cloud reconstruction

4.1 Lifting wavelet

Lifting wavelet is a special wavelet that is another expression of image as same as Fourier transformation. An image and its wavelet image are corresponding, that means they are isomorphism. The wavelet image contains high frequency and low frequency that express the edge or flat area of the image. Unlike Fourier, the basis of wavelet is not defined, thus the frequency coefficient is different with different basis. Therefore a lot of researches have been focused on wavelet basis[17-18]. Harr basis is one of popular bases.

4.2 The method of pixel fusion

The purpose of pixel fusion is to fuse different pixels into one pixel as some rule. There are many methods in pixel fusion. The simplest one is average method that declare: $P_{fusion} = average(P_{left} + P_{right})$, where $average$ means average function such as geometric average, harmonic average and arithmetic average. However, average method usually takes consideration of two single points and not the global distribution of the image. In view of the difference between high frequency and low frequency of an image, wavelet can take different fusion rules, so it is more flexible than average. The paper will utilize lifting wavelet based on Harr basis to fuse pixels of corresponding images.

The method of this paper can be divided into two parts: stereo matching and 3D point-cloud reconstruction based on pixel fusion. The steps are demonstrated below:

Stereo matching and obtaining of disparity map

Let the range of disparity be $[d_{\min}, d_{\max}]$, the searching window size is $2N+1$, the process of PED on stereo matching is:

1).parallel sampling. For each point $p:(i,j)$ of left image, two group of $M \in [0, d_{\max}]$ samples(obeying uniform distribution) $d_1, d_2, ..., d_M$ and $d_1', d_2', ..., d_M'$ are chosen randomly in right image which ranges $(i - d_{\max}, j) \to (i - d_{\min}, j)$;

2).Computing sufficiency. Computing the potential energy difference $E(p,\bar{p}_{d_m})$ and $E(p,\bar{p}'_{d_m})$ of windows whose size is $2N+1$ and center is (i,j) of two images;

3).Choosing superior samples and updating probability distribution model. The $M/2$ samples $D_1=\{d_{11},d_{12},...,d_{1M/2}\}$ and $D_2=\{d'_{11},d'_{12},...,d'_{1M/2}\}$ with low potential energy difference will be chosen to update model as $d_{\min}=\min\{D_1\bigcup D_2\}, d_{\max}=\max\{D_1\bigcup D_2\}, M\leftarrow\min\{M/2, d_{\max}-d_{\min}\}$. If the number of samples this time is less than threshold T_d or $d_{\max}-d_{\min}<T_d\,(T_d=4)$, go to Step 4), else $i{+}{+}$ and return Step 1);

4).Obtaining disparity or occlusion determination. Choose the sample point that is nearest to the mean of samples and computing the potential difference at this time. If the difference is less than a threshold, the point is regarded as the matched point, else it is an occlusion possibly. For an occlusion, we will confirm matched point inversely. If the matched point is (i,j), it is not an occlusion, else it's an occlusion. The disparity of occlusion can be computed by bilinear interpolation;

5).Final process of disparity image. Utilize median filter to smooth disparity map.

2. Spatial point-cloud pixel fusion

1).For the pixels sequence $l_i=\{l_{i1},l_{i2},...,l_{in}\}$ of each row of left image and corresponding pixels $r_i=\{r_{i1},r_{i2},...,r_{in}\}$ of right images, lifting wavelet transformation will be taken to them. The transformation result is $f(l_i)$ and $f(r_i)$;

2).Computing the harmonic average of high and low frequency coefficient of $f(l_i)$ and $f(r_i)$. And Get fused wavelet transformation point data $f(fus_i)$;

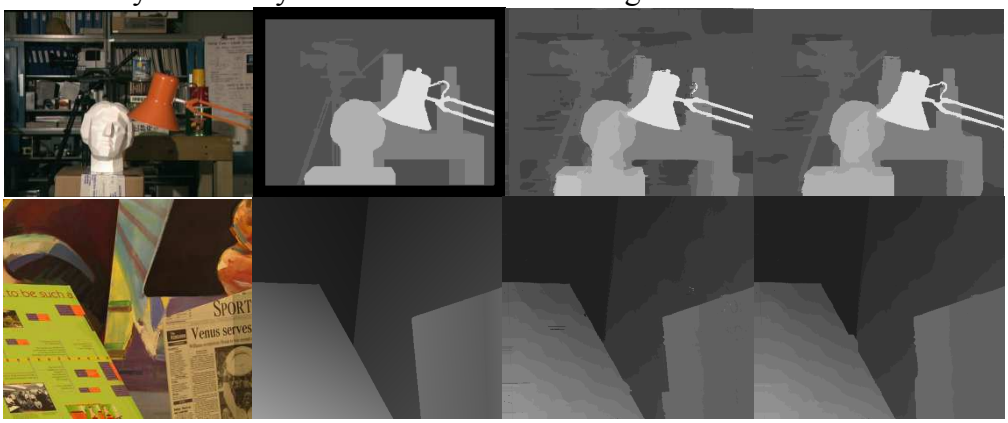
3).In order to get actual fused image pixels, inverse transformation is taken to $f(fus_i)$. And according to the disparities of these pixels, the point-cloud is constructed.

Because the chosen samples with high sufficiency are half of the sum in stereo matching, the number of sample is $2M/2^K$ after K iterations. The algorithm converges by exponent of 2. Besides, the initial samples obey uniform distribution and due to random sampling, the difference of maximum and minimum disparity is close to the half of origin difference after each iteration. Finally, the samples will converge to a best sample or a sample region.

The result of analysis of experiment and simulation

5.1 Experiment result of disparity map

This paper combines OpenCV with OpenGL and simulates on Visual Studio 2008 for two groups of images of Middlebury University. The result is shown in Fig 1.



(a) (b) (c) (d)

Fig 1. Images and disparity maps.(a)Source images.(b)True disparity maps.(c)The disparity maps of ASW.(d) The disparity maps of our algorithm.

In the experiments, although there are not too many mutations in our algorithm, some errors still appear in some regions such as edges. The number of matching cost of ASW is $H\times W\times(d_{\max}-d_{\min}+1)$ (H, W: height and width of image, $d_{\max}$, $d_{\min}$:the initial max and min disparity). So the time complexity of ASW is $H\times W\times(d_{\max}-d_{\min}+1)$. The samples with high sufficiency on the second and third step of PED are around the true disparity. The time complexity of this paper is approaching to $H\times W\times(d_{\max}-d_{\min}+1)/2$ that is half of ASW in theory. Because of the influence of other factors of program, the time consumption of our algorithm is little more than half of ASW. The compared result is shown in Table I.

Table 1. The time of Tsukuba and Venus from ASW and our algorithm

Image group	Tsukuba(s)	Venus(s)
ASW	52.48	61.37
Our algorithm	28.54	35.28

From Table 1, our average time of stereo matching is 54% and 57% of ASW. Obviously, the time is more decreased than ASW.

5.2 Simulation of spatial point-cloud fusion

(a) (b) (c)

Figure 3. Left and right images with their final disparity maps of this paper.(a)Left image.(b)Right image.(c)Their final disparity maps.

According to Section4.2, the left and right image which are shown in Figure 5.3(a)(b) will be fused by lifting wavelet and 3D point-cloud will be constructed. The result of point-cloud is shown in Fig 4.

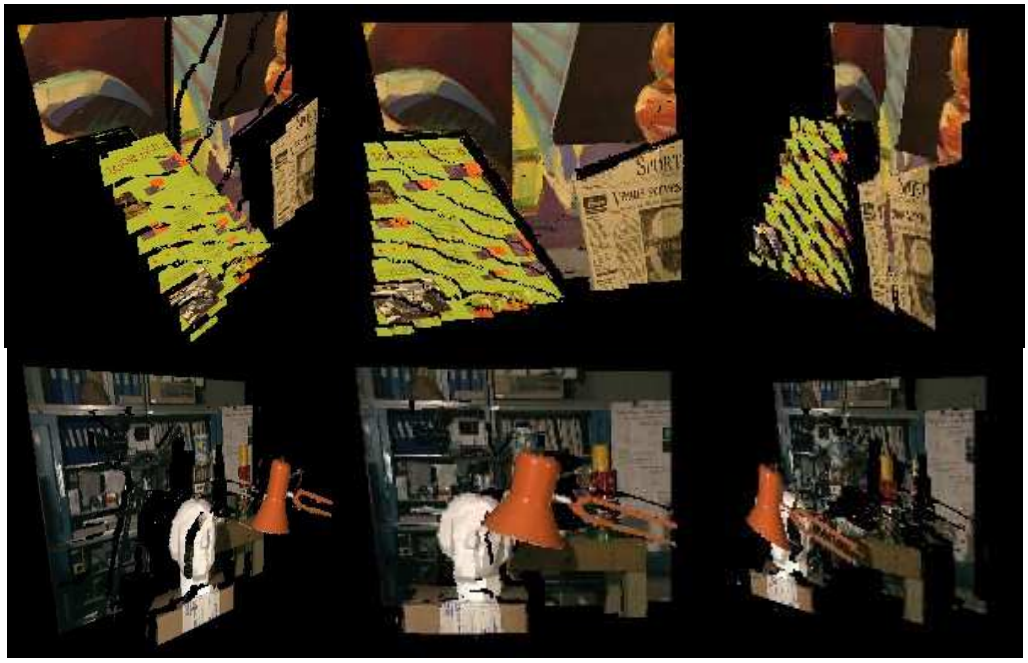


Fig 4. Three view orientation of 3D spatial point-cloud.

Conclusion

This paper utilizes improved ED named Parallel ED to stereo matching and the speed is increased. Parallel method could reduce the probability of local optimum of ED. Because the

samples are taken parallel, the time complexity will be converged by exponent of 2, and samples will be converged to the optimum. Therefore, the speed in our algorithm is more quicker than in ASW obviously, but it still can't avoid local optimum absolutely. In future works, we will add more conditions to decrease the affect of ED's defect.

Keywords: Weighted Modeling context; Genome Compression; Adaptive Code Length

Abstract. The genome compression algorithm based on the weighted context model is present in this paper. In this algorithm, the method to construct the weighted context model is discussed. The adaptive code length of the context models are used to determine the values of the corresponding weights of models. In the coding process, the values of these weights are modified in order to achieve the minimum code length and to enhance the compression efficiency. At last, the proposed algorithm is used to the bacteria genome compression. The experiments results indicate that the algorithm present could produce better compression result than the results by other algorithms.

Introduction

The rapid genome sequencing technology makes the scale of the genome data increasing exponentially. Although the storage technology has developed rapidly during the past decade, the current storage capacity for saving these genome date is also insufficient. The genome compression is one of efficient approaches to enhance the genome storage efficiency. The first research of the genome compression could be retrospected to the Grumbach's work. In[1], the genome compression algorithm, *BioCompress*, is proposed. In this algorithm, the compression operation is executed by the substitutional procedure as the same as the Lempel-Ziv algorithm done. In the coding process, the genome is separated into two parts, one is the repeated regions and another is the non-repeated regions. The substitutional method is used for the repeated regions coding, but each base in the non-repeated regions is encoded by allocating the code words with 2 bits. As the modified algorithm, the *BioCompress-2*[2] use the 2-order Markov model for coding the bases in the non-repeated regions. However, when the number of the repeated sequence which are added into the dictionary become vaster and vaster, the costs to encode the points of the repeated sequence in the dictionary become too high. The algorithm *GenCompress*[3] is proposed to tackle this problem. In this method, the differences, which are between the exact repetitions in the dictionary and the coding sequence, are encoded. The code length of the genome sequence achieved by this algorithm actually include two parts, one is the code length for coding the repeated sequence point in the dictionary, another is the code length for coding the differences. The difference contain two kinds of information, the positions of the sequence on where the difference happened and the difference itself. In this algorithm, the scale of the dictionary is reduced and the code length for coding the repetition sequence point is shorten, but more information in this algorithm is needed to be encoded. Therefore, *GenCompress* increase the compression rate only a little. In[4], the algorithm *CTW+LZ* is proposed, in this algorithm, the entropy coding based on the Context model is used to encode the short repetitions and the non-repetitions sequence. For the long repetition sequence, the LZ algorithm is deployed to allocate the code words. In this algorithm, the modeling context entropy coding technology is introduced in the genome compression for the first time, the statistic property between the bases is used to produce the satisfactory compression performance. In[5,6], two algorithms which use the statistic models to compress the genome sequence are proposed. In[5], some models which are used for describing different types of regions in the genome sequence are constructed, each model is named by a "expert". Subsequently, each base in the genome sequence is encoded independently by the mixture model of these models. In[6], the compression algorithm based on the mixture finite context model is proposed and its application to compress the bacteria genome sequence is discussed. The performance of this algorithm is better than other algorithms, but the calculation of the weights needs more manual intervention.

Meanwhile, the context models with k orders have different describing complexities for coding the symbols. In[7], the discussion that the adaptive code length is equivalent to the describe complexity of the model is given. When the context model, which is obtained by combining some models with k orders, are used to code the symbols, the value of the weights of these models should be related to their adaptive code length. The models with high adaptive code length should be used as little as possible. Otherwise, the models with take higher value of the weight.

In this paper, the bacteria genome compression algorithm based on the weighted context model is present. Some context models with different orders are constructed to describe the statistic properties of the bases in the genome sequence, the determination of the value of the weights is corresponding to the adaptive code length of each model. Then the mixture model is used for coding the bases.

Context Modeling with Finite Orders

A. Context modeling

Considering the sequence $x_n \ldots x_0$, its code length is described by the representation $-\log P(x_n \ldots x_0)$, where $P(x_n \ldots x_0)$ denotes the joint probability distribution of $x_n \ldots x_0$. In practice, this distribution is not known. We use the past k symbols of the current symbol x_n to construct the conditional probability distributions $P(x_n \mid x_{n-1},\ldots,x_{n-k})$ and then use this distribution for coding the symbol x_n. In this case, the code length of the sequence could be represent by (1).

$$L = -\sum_{i=0}^{n} \log P(x_i \mid x_{i-1} \ldots x_{i-k}) \tag{1}$$

There are $I^k * I$ conditional probabilities should be estimated firstly. The estimation method is the counting statistic approach, which is represent by (2).

$$p(x_i = j \mid x_{i-1},\ldots,x_{i-k}) = \frac{n_j + \delta}{\sum_{j \in I} n_j + I\delta} \tag{2}$$

Where n_j denotes the counts of the $I-ary$ symbol $x_i = j$ whose condition vector is $x_{i-1},\ldots,x_{i-k}$ and δ denotes the initialize number of counts of the symbol x_i. This estimation procedure is referred to as the Context modeling with order k. According to the information theory, if the number of the conditions increase, the entropy of the conditional probability distribution $P(x_n \mid x_{n-1},\ldots,x_{n-k})$ is likely to be reduced, i.e, the code length may be shorten when this conditional probability distribution is used for the entropy coding. However, due to the "Context dilution", it does not always mean that the more number of the conditions, the shorter code length could be achieved[8]. During the training precess, if one conditional probability distribution obtain only a little number of counts n_j, the estimation (2) is not "mature". It follows that the code length may not be shorten when this distribution is used for coding. The describe complexity of the model is defined to represent the mature extent of the model. In our previous work, we find that the adaptive code length is equivalent to the model describe complexity. The adaptive code length of one conditional probability distribution could be calculated by (3)

$$L_m = \sum_{s=0}^{S_m - 1} \log(s + I\delta) - \sum_{j=0}^{I-1} \sum_{i=0}^{n_j - 1} \log(i + \delta) \tag{3}$$

Where L_m denotes the adaptive code length of the m_{th} conditional probability distribution in the context model with order k, S_m denotes the number of the training data the m_{th} conditional probability distribution obtained. There are $M = I^k$ conditional probability distributions in the context model. Then the total adaptive code length of this $k-order$ context model, L^k, is represented by (4)

$$L^k = \sum_{m \in M} L_m \tag{4}$$

L^k describe the complexity of the model when this model is used for coding. The context models with different orders may have diverse describe complexities. If only one context model is used for coding, the code length should not be shorten until this model become "mature"(with low describe complexity). The weighed context model is one efficient approaches to tackle this problem.

B. Weighted Context Modeling

The conditional probability distribution $P(x_n \mid x_{n-1},\ldots,x_{n-k})$ implies the prediction of the symbol x_n by conditioning the past k symbols. The prediction is essentially the max-likelihood estimation. We expect that the uncertainty of x_n could be reduced by conditioning as far as possible. Theoretically, the more number of conditions, the more the uncertainty could be reduced. But this conclusion is based on the fact that the conditional probability distribution is "mature". In practice, whether the conditional probability distribution is mature or not is unknown. It follows that the coding cost is too large before these distributions become mature. Then the conflict comes up, the distributions which contain more number of conditions could reduce more uncertainty but lead to higher coding cost. A approach to alleviate this conflict is to combine some conditional probability distributions which contain various number of conditions. One method for combination is Bayesian model averaging. It is represented by (5)

$$P(x_i) = \sum_{k \in K} P(x_i \mid x_{i-1},\ldots x_{i-k}) w_k \tag{5}$$

Where $P(x_i)$ denotes the prediction of the symbol x_i by combining K conditional probability distributions which contain k conditions for each. $w_k, 0 \le w_k \le 1$ denotes the value of the weight of the conditional probability distribution with k conditions. In[6,7], some methods to determine the value of the weights are discussed. In[7], the impulse response of one filter is used to calculate of the value of the weights. However, the results by this method rely on more manual intervention. And in[6], the value of the weights are calculated by (6)

$$w_k \propto 2^{-3 AvgLen(x_{n-k},\ldots,x_n \mid \theta_k)} \tag{6}$$

Where $AvgLen(x_{n-k},\ldots x_n \mid \theta_k)$ denotes the average code length of the sub-sequence $x_{n-k},\ldots,x_n$ which is encoded by the context model θ_k with order k. The constant parameter 3 is the empirical value. The values of the weights in this algorithm are determined only by the average code length of a part of sequence, it does not utilize the statistical correlation of the training data sufficiently. The purpose of constructing the conditional probability distribution is to reduce the uncertainty of the symbol. The conditional entropy of the conditional probability distribution implies the average uncertainty of this distribution, i.e, the low bound of the code length when this distribution is used for arithmetic coding. However, the conditional entropy could not be known unless the conditional probability distribution is determined. The adaptive code length implies the complexity of the context model, we have a good reason to believe that in the coding process, if the total adaptive code length of one $k-order$ context model is minimum, then this model is effective to encode the next symbol. In the combination process, the model with short adaptive code length should play more role for coding, i.e, higher value of the weight should be given. In our work, the value of the weights are determined by the adaptive code length, which is described by (7)

$$w_k = \frac{L_{\max}^K - L^k}{\sum_{k \in K} L_{\max}^K - L^k} \tag{7}$$

Where L^k denotes total adaptive code length of the context model with the order k, $L_{\max}^K$ denotes the maximum value of the total adaptive code length of all context models with orders k ($k \in K$). By this method, the context model with shorter adaptive code length will assign the higher value of weight. Specially, the model which is corresponding to the maximum adaptive code length will have the value of the weight equaling to value 0. Then we could obtain the combination of the context model by (5) and (7).

C. Bacteria genome compression based on the weighted context model

In this section, the bacteria genome compression algorithm based on the weighted context model is proposed. The genome sequence could be described by a $4-ary$ source. Each symbol(each base) takes its value in the alphabet $\{A,T,G,C\}$. According to the recent research, the correlation is existing among the bases. These correlations should be utilized when the entropy coding based on the modeling context is used for genome compression. We construct the condition probability

distributions to predict the base symbol by choosing the past k bases for conditioning.The weighted context model is considered to combine the context model with different orders, the values of the weights are calculated by (7). In practice, with the coding process, the conditional probability distributions will obtain more and more counts of the symbols, i.e, some context models may become mature, then the adaptive code length of the context models should be updated. In order to achieve this updating process, a parameter N_t is given to control the time of the updating process happened. When the number of the coded symbols reaches the value of N_t ,or $C*N_t$ (C is integer), the update process takes place. Then $C*N_t$ is the threshold of the update process. If the weights are updated, the new weights will take part in the next coding procedure. The algorithm follows as:

Step1: Construct context models with different k orders.

Step2: Using the training data to estimate these conditional probability distributions in the context models by (2).

Step3: Calculating the total adaptive code length for each context model by (3) and (4). Then calculating the value of the weight of this context model.

Step4: If the number of the coded symbols do not reach the threshold $C*N_t$, continue step5, otherwise, go back to step3 to update the weights.

Step5: Combining the context models, Using the conditional probability distribution combined to drive the arithmetic encoder to assign the code word for each base.

Experiments

In this paper, we use the entropy coding based on the weighted context model to compress the bacteria genome sequence. The genome sequence is obtained from the National Center for Biotechnology Information (NCBI) directory ftp://ftp.ncbi.nih.gov/genomes/Bacteria/. The genome data for our experiment contains 2338 sequences and the number of bases is ranging from 1286 to 13033779. We construct 7 context models with orders equals {3,7,8,10,15,20,30}respectively. The parameter N_t equals 10000.

We use two sequences *NC_013929*(10148695 bases) and *NC_014318*(10235715 bases) to train 7 context models respectively. Other three sequences(*NC_013595*, *NC_013131* and *NC_010162*) are used as the source sequences. In experiment 1, we observe the updating process of the weights, the value of the weights in the first 5 updating processes are listed in Table I(Keep two decimal places).

Table I. The value of the weights from first 5 updating processes

Times	w_3	w_7	w_8	w_{10}	w_{15}	w_{20}	w_{30}
1	0.16	0.19	0.20	0.18	0.15	0.12	0
2	0.15	0.19	0.20	0.19	0.14	0.13	0
3	0.14	0.18	0.22	0.20	0.15	0.11	0
4	0.12	0.19	0.19	0.21	0.17	0.12	0
5	0.09	0.17	0.16	0.20	0.21	0.17	0

From Table I, with the coding process, the value of the weights is updated. When more bases which are coded take part in the counting process, the context models with higher orders play more roles for enhance the coding efficiency. Actually, when the updating process is executed 20 times, i.e, 200000 bases are coded, the weights w_{10} and w_{15} will become larger than other weights, in this case, the context models with order 10 and 15 provide the better compression performances than other models. When the number of bases coded reach 3400000, the weight w_{30} will join in the combination to provide more information to predict the current symbol.

In experiment 2, three bacteria genome sequence are used as the source sequence, the same weighted context model as the experiment 1 used is deployed. The bit rate of these genome sequence is given in Table II. For comparison, the compression result by the “expert method” algorithm (XM) in[5] and the result by the finite context model algorithm (FCM) in[6] are also listed in Table II. The results by these algorithm is from [6].

Table II. The comparison of results:

sequence	Number of bases	Results (bit/base)		
		XM	FCM	Our Algorithm
NC_013595	10341314	1.796	1.759	1.742
NC_013131	10468872	1.817	1.779	1.770
NC_010162	13033779	1.755	1.743	1.732

Apparently, from Table II, the results by our algorithm are better than the results by other two algorithms. Although the execution time of our algorithm is higher than the time the FCM needed, but the time our algorithm spent is lower than the time for XM. Meanwhile, in our algorithm, the value of the weights is determined by the adaptive code length and these weights could be modified during the coding process. At last, the code length by our algorithm is minimized.

Conclusion

The bacteria genome compression algorithm based on the weighted context model is present in this paper. The context models with different orders are constructed to predict the genome base. When the weighted context model scheme is deployed for coding, the values of these weights are determined by the adaptive code length of the context models. During the coding process, the value of these weights could be modified dynamically in order to achieve the shortest code length. The experiment results indicate that our algorithm produces better result for the compression of the bacteria genome than the results by other algorithms.

Abstract. Blind source separation (BSS) is a technique for recovering a set of source signals without priori information on the transformation matrix or the probability distributions of the source signals. In the previous works of BSS, the choice of the learning rate would reflect a trade-off between the stability and the speed of convergence. In this paper, a particle swarm optimization (PSO)-based learning rate adjustment method is proposed for BSS. In the simulations, three source signals are mixed and separated and the results are compared with natural gradient algorithm. The proposed approach exhibits rapid convergence, and produces more efficient and more stable independent component analysis algorithms than other related approaches.

Introduction

Blind source separation (BSS) is the process of extracting unknown independent source signals from sensor measurements which are unknown combinations of the source signals. Initially inspired by signal separation in the human brain, BSS has recently become a very active research area both in statistical signal processing [1] and unsupervised neural learning [2]. The goal of BSS is to recover the waveforms of unobserved signals from observed mixtures without knowing the mixing coefficients.

So far the theory of BSS has been successfully approached in linear instantaneous mixing model. The key to solving the BSS problem is directly linked to finding a stable learning algorithm. The choice of the learning rate directly affects the stability and speed of convergence. A fixed learning rate and a step reduction learning rate adjustment are both classified as nonadaptive. Most of the known nonadaptive learning algorithms for blind separation of source signals assume the global learning rate is a small positive constant, either fixed or exponentially decreasing from a large value to zero[3]. The main disadvantage to these learning rate adjustment approaches is the inability to separate signals with stability and efficiency.

Several typical adaptive learning rate selection methods for ICA have been developed [4]. An adaptive step-size technique for BSS, natural gradient algorithm, was proposed in [5]. The disadvantage of this approach concerns the selection of the auxiliary variable matrix. The selection is difficult and cannot guarantee stability in the overall system. The method was also not based directly on the separation states of the source signals.

As opposed to these previously mentioned methods, this paper adopts particle swarm optimization (PSO) to find a suitable learning rate for BSS, and also extends its search space to save evolution time, making the system more flexible in adapting to the online learning requirement.

Blind source separation

The blind source separation problem can he modeled as follow:

$$x(t) = A \cdot s(t) \tag{1}$$

Where $x(t) = [x_1(t), x_2(t) \ldots x_m(t)]^T$ is the available vector of observations and $A = [a_{ij}] \in R_{m \times n}$ is the unknown mixing matrix, modeling the environment in which signals are mixed, transmitted and measured [6]. We assume that A is a non-singular n×n square matrix. The goal of BSS is to find a non-singular n×m separating matrix B such that extracts sources via

$$y(t) = B \cdot x(t) = B \cdot A \cdot s(t) = G \cdot s(t) \tag{2}$$

Where $y(t) = [y_1(t), y_2(t) \ldots y_m(t)]^T$ is an estimator of the sources. The separating matrix has a scaling freedom on each row because the relative amplitudes of sources in s(t) and columns of A are unknown. The transfer matrix $G = B \cdot A$ relates the vector of independent signals to its estimators.

In order to separate the independent sources from their linear mixtures, we expect the outputs of the separation system lo be mutually statistically independent. For this purpose, we must utilize a measure of independence between random variables. Thus, we introduce the concept of negative entropy as:

$$J(w_i) = E(G(w_i^T x)) - E(G(v)) \tag{3}$$

Where G (•) are some non-quadratic functions, and v is a random variable with standard normal distribution.

By finding the projection direction w_i which makes J (w_i) maximum, an independent component can be extracted. If J (w_i) takes the maximum value, $E(G(w_i^T x))$ will also have the maximum value, and the extreme point w_i is the solution of equation

$$E(Xg(w_i^T x)) = 0 \tag{4}$$

Where g (•) is the derivative of G (•). According to Newton iteration theorem, we have

$$w_i^+ = w_i - \frac{E(Xg(w_i^T x))}{E(X^T Xg'(w_i^T x))} = w_i - \frac{E(Xg(w_i^T x))}{E(g'(w_i^T x))} \tag{5}$$

Where $E(X^T Xg(w_i^T x)) = E(X^T X)Eg(w_i^T x) = E(g(w_i^T x))$ .Multiply the two sides of (5) with $E(g'(w_i^T x))$ and let $w_i^* = E(g'(w_i^T x))w_i^*$, we have

$$\begin{cases} w_i^* = E(Xg(w_i^T x)) - E(g'(w_i^T x))w_i \\ w_i = \dfrac{w_i^*}{\|w_i\|} \end{cases} \tag{6}$$

By conducting iteration according to (6), the w_i^T obtained through convergence corresponds to the row vectors of the separation matrix W, and then an independent component can be extracted.

Particle swarm optimization

Particle swarm optimization (PSO) is a population based optimization technique that was proposed by Kennedy and Eberhart [6] in 1995 in which the population is referred to as a swarm. The particles express the ability of fast convergence to local or global optimal positions over a small number of generations.

A swarm in PSO consists of a number of particles. Each particle represents a potential solution of the optimization task. All of the particles iteratively discover the probable solution. Each particle generates a position according to the new velocity and the previous positions of the cell, and is compared with the best position which is generated by previous particles in the cost function and keeps the best one; i.e., each particle accelerates the directions not only the local best solution but also the global best position. If a particle discovers a new probable solution, other particles will move closer to it so as to explore the region more completely in the process [7].

Let N denote the swarm numbers. In general, there are three attributes, current position li, current velocity v_i and past best position Pb_i, for particles in the search space to present their features. Each particle in the swarm is iteratively updated according to the aforementioned attributes. Assuming that the objective function f is to be minimized so that the dimension consists of n particles and the new velocity of every particle is updated by (7).

$$v_{ij}(t+1) = wv_{ij}(t) + c_1 r_{1,i}(t)[Pb_{ij}(t) - l_{ij}(t)\} + c_2 r_{2,i}(t)[Gb_i(t) - l_{ij}(t)] \tag{7}$$

where v_{ij} is the velocity of the jth particle of the ith swarm for all $i \in 1 \ldots N$, w is the inertia weight of velocity, c_1 and c_2 denote the acceleration coefficients, r_1 and r_2 are elements from two uniform random sequences in the range (0, 1), and t is the number of generations. The new position of the ith particle is calculated as follows:

$$l_{ij}(t+1) = a_{ij}(t) + v_{ij}(t+1) \tag{8}$$

The past best solution of each particle is updated by:

$$Pb_{ij}(t+1) = \begin{cases} \mathrm{Pb_{ij}}(t), \text{ if } \mathrm{f(I_{ij}}(t+1)) \geq f(Pb_{ij}(t)) \\ \mathrm{I_{ij}}(t+1), \text{ if } \mathrm{f(I_{ij}}(t+1)) < f(Pb_{ij}(t)) \end{cases} \tag{9}$$

The global best position Gb will be found from all particles during previous three steps are defined as:

$$Gb_{ij}(t+1) = \arg\min_{\mathrm{Pb_{ij}}} \mathrm{f(Pb_{ij}}(t+1)), 1 \leq \mathrm{j} \leq \mathrm{n} \tag{10}$$

The BSS algorithm based on PSO can be implemented as the following iterative procedure:

1) Set the iteration number N to zero, an initial population w_i and v_i of size is created from a random initial set of parameters.

2) The fitness for each particle w_i is evaluated using (3).

3) The best previous position of the ith particle is recorded and represented as p_i, i=1,2, …N.

4) The index of the best particle among all the particles in the population is represented as p_g.

5) Change the velocity vector for each particle using (7).

6) Move each particle to its new position using (8).

7) Let N=N+1.

8) Go to step 2), and repeat until convergence. Terminate the iterative procedure.

9) Output the panicle W with the best fitness value and compute the separated signals y(t) = Wx(t).

Simulation

In order to verify the validity and performance of the proposed algorithm, computer simulations are conducted to test the PSO-based method to blind separation of independent sources from their linear mixtures.

Consider the mixing case of three independent random signals: a sinusoidal signal, a triangular wave signal and a random noise signal uniformly distributed in interval [-1, 1]. There are 200 samples from each signal (N=200). The mixture matrix A is chosen randomly.

Fig.1 and 2 show source signals and their mixtures. The separated signals which are the estimations of source signals are obtained by the demixing model adapted in this paper. The parameters of PSO are summarized as follows: The population size of the swarm is 20. The number of iterations is 40. We suppose that g_j=1, so the dimension of search space is selected as 4.

Constants c_1=c_2=2, r_1 and r_2 are two independent random numbers uniformly distributed in the range of [0, 1]. The inertia weight w is reduced linearly from 0.9 to 0.4 during the search. The separated signals obtained with the proposed method (PSO-based) are shown in Fig.3. In order to compare, we also separate the signal with natural gradient algorithm, which is shown in Fig.4.

Separated signals and source signals of the two algorithms are inconsistent in order, and they have different amplitude and phase, which illustrate the two uncertainties of blind source separation. In order to evaluate the separation effect of the two methods, this paper adopts similar coefficient of source signal and separated signal ζ_{ij} as the performance indicator, that is:

$$\xi_{ij} = \frac{\sum_{k=1}^{n} y_i(k) s_j(k)}{\sqrt{\sum_{k=1}^{n} y^2{}_i(k) s^2{}_j(k)}} \tag{11}$$

Similar coefficient between source signal and separated signal based on algorithm in this paper and natural gradient algorithm are shown in table 1.

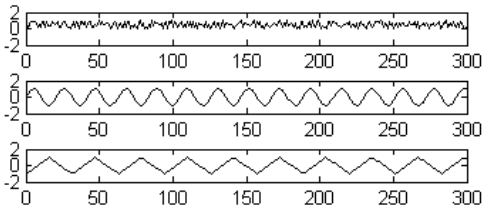

Fig.1 Source signals

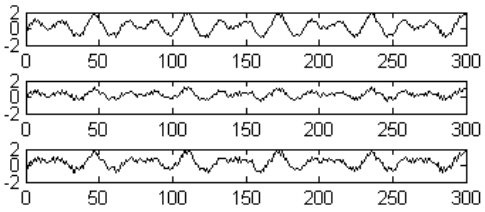

Fig.2 Mixed signals

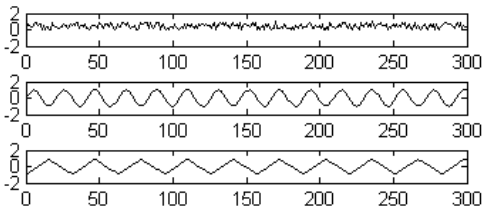

Fig.3 Separated signals obtained with the algorithm in this paper

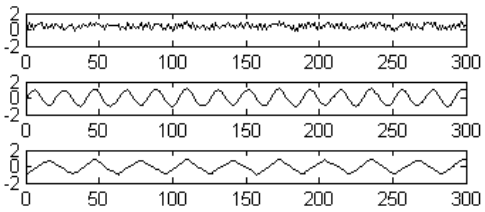

Fig.4 Separated signals obtained with natural gradient algorithm

Table 1. Similar coefficient between source signal and separated signal

similar coefficient	sinusoidal signal	triangular wave signal	random noise signal
algorithm in this paper	0.973	0.964	0.985
natural gradient algorithm	0.866	0.879	0.921

As is shown in table 1, similar coefficient of the algorithm in this paper is closer to 1 than natural gradient algorithm, which shows the separation effect of this algorithm is batter than that of natural gradient algorithm.

Conclusion

A new blind source separation method based on particle swarm optimization algorithm has been proposed in this paper. Simulation results show that the proposed method can obtain clearer estimations of source signals from their mixtures, which overcome the drawback of traditional approaches to BSS such as natural gradient algorithm effectively.

Keywords: Particle Swarm Optimization Algorithm; Clustering; Earthquake prediction; Swarm intelligence

Abstract. Data mining technology based on the particle swarm optimization algorithm applied in earthquake prediction was presented. Making use of the characteristics of abnormally high-dimensional data of earthquake precursor, this paper studies an earthquake prediction model based on *the Particle Swarm Optimization Clustering Algorithm*. This model analyzes the relationship between earthquake precursor data and earthquake magnitude. Inputs are 14 abnormal indexes such as belt, seismic gap and short leveling, and output is earthquake magnitude classification. The cluster average-distance is set as the evaluation function of the Particle Swarm Optimization Algorithm. The experimental results indicate that, this model can effectively and validly predict the earthquake magnitude in accordance with the earthquake precursor data. Compared with the traditional clustering k-means Algorithm model, this stability is stronger, and the correctness of forecast is much higher. Through the research and analysis of the example of history source seismic data, the model of this paper is one of approaches to improve the efficiency of earthquake forecast.

Introduction

The research of traditional earthquake prediction is established on people's analysis on earthquake cases data and precursor observation data. However, with the rapid development of precursor observation data on seismic network and in-depth study on earthquake prediction, this method cannot meet the practical needs [Ref. 1].

Tasks of data mining can be summarized as two types in general: descriptive mining of mass data and predictive mining. With the continuous development of data mining, various data mining algorithms in the application fields such as financial analysis, communication operation, biotechnology and intrusion detection have been extensively and intensively studied; this technology also has broad application prospects in earthquake prediction [Ref. 2].

Some representative studies are proposed. Literature [Ref. 3] extracted the earthquake magnitude recognition causal relationship through a large number of sample learning using neural network method, but this model depended on sample selection with poor reusability, and the problem of calculation convergence needed to be studied. Literature [Ref. 4] put forward a new fuzzy rule extraction method, adopted the subtractive clustering based on mountain function to self-adaptively confirm the center of clustering and gave 4 fuzzy rules of earthquake magnitude prediction which were based on the long axis of seismogenic gaps. Since this method is based on the training rule of self-organizing neural network model, it is also a magnitude prediction model based on effective samples, and the prediction rule only considers one type of many precursor observation data.

To apply the data mining techniques for very large databases that the earthquake researchers learn to study, this paper puts forward an earthquake prediction method based on Particle Swarm Optimization Clustering Algorithm and establishes a new earthquake prediction model, facing the multidimensional characteristics of precursor data, and utilizing the distributive and self-organizing feature of swarm intelligence. This method overcomes dependence on data sample selection of the neural network method, and it does not need to design network topology. The analysis on data of history source earthquake cases and experimental results indicate that, this model is superior to the

classic k-means clustering algorithm. The stability is stronger, and the accuracy of forecasting earthquake magnitude is much higher.

Principle of Particle Swarm Optimization Algorithm

Swarm intelligence research mainly includes ant colony algorithm and Particle Swarm Optimization Clustering Algorithm [Ref. 5]. Particle Swarm Optimization Algorithm is a novel evolutionary algorithm. Kennedy and Eberhart put forward it in 1995 through observational study on certain behaviors of bird flock, shoal of fish and human society [Ref. 6].

Particle Swarm Optimization (PSO) is an emerging, heuristic, global random search algorithm based on swarm intelligence, it has the characteristics of easy understanding, easy realization and strong global searching capability, etc. Many scholars research this method to establish models, promote and apply it to data analysis [Ref. 7].

Like other evolutionary algorithms, PSO Algorithm is also based on the concept of "population" and "evolution" and realizes the search for optimum solution of complex space through cooperation and competition among individuals. Meanwhile, PSO does not need to conduct evolutionary operator operations such as cross, mutation and selection for individuals. Therefore, PSO has good biological social background and few parameters. It is easy to understand and realize, and has strong global searching ability for nonlinear and multimodal problems.

Earthquake Prediction Based on the Particle Swarm Clustering

Data background

The seismologic abnormal indexes may be divided into two categories of seismometry index and precursory index. In the book of "Earthquake Cases in China", according to the statistics of observation means, it has 74 indexes for the former seismometry abnormal index and has 84 indexes for the latter precursory abnormal index. The meanings of these indexes are laid out in a guide to the seismological analysis and prediction method. Some scholars specially study on the algorithm for simplifying that how to select the core abnormal indexes from the numerous complex seismic abnormal indexes.

This paper selects the typical earthquake case to verify the earthquake prediction method based on the particle swarm clustering algorithm, and 14 abnormal indexes may be considered. In the experiment of the experimental data by Ref. 3, the earthquake magnitudes are divided into three groups, the first group is three times of seismic sequence of Magnitude 7 above, the second group is nine times of seismic sequence of Magnitude 6 to Magnitude 6.9, the third group is 18 times of seismic sequence of Magnitude 5 to Magnitude 5.9.

Steps of Algorithm

Earthquake prediction model based on the Particle Swarm Clustering Algorithm can be described as follows:

1) The original data of earthquake cases shall be normalized to eliminate the dimensional effect.

Interval values normalized transformation approach is used for the processing of dimensionless of each dimension data, assuming that data sample set is $\{x_{i,j} \mid i=1,2,;n;\ j=1,2,;k\}$, herein, $x_{i,j}$ represents the j dimension value of the i sample, n represents numbers of samples, p represents numbers of dimensions of samples. Normalized sample can be expressed as $x_{i,j}^{'}$, and calculated as shown in Eq. 1:

$$x_{i,j}^{'} = \frac{x_{i,j} - \min\limits_{j}(x_{i,j})}{\max\limits_{j}(x_{i,j}) - \min\limits_{j}(x_{i,j})} \tag{1}$$

Here $\max\limits_{j}(x_{i,j})$ and $\min\limits_{j}(x_{i,j})$ represent the maximum and minimum values of the j dimension data sample respectively.

2) Parameters of initialization algorithm.

Set particle numbers as n, position and velocity of each particle as x_i and V_i respectively, and initial value of r_1 and r_2 is determined as 0, and uniform random number will be automatically selected by the program within the range of [0，1] to calculate and update position and velocity of each particle.

3) Pick up the speed through applying Particle Swarm Optimization Algorithm, and design the update strategy.

4) Design the evaluation function.

If the algorithm satisfies the evaluation function, the algorithm needs to be stopped, and output the optimal solution. Otherwise, it needs to turn to the step 3.

Experimental Results and Analysis

In order to verify and prove the correctness and efficiency of earthquake forecast which is based on Particle Swarm Optimization Algorithm, an experiment in the environment of Matlab 2007a is conducted and a comparison with the classical k-means Clustering Algorithm is made.

Analysis on experimental result and accuracy

After repeated experiments, particle swarm numbers in algorithm is set as 500, parameters are set as α=0.8 , k^+=0.8 , k^-=0.2 . Fig. 1 shows clustering result of pedigree diagram.

As can be seen from Fig. 1, the Particle Swarm Clustering Algorithm is better when applied for earthquake prediction. From analysis on data, the overall forecast accuracy rate of k-means Algorithm is only 73.3%, however, Particle Swarm Optimization Algorithm can increase the accuracy rate up to 83.3%. Compared with results of k-means Algorithm, we can find that Particle Swarm Optimization Algorithm can distinguish magnitudes of less than 6 from magnitudes of more than 7 completely correctly.

Analysis on stability and time complexity

From the analysis on steps of algorithm and code, we can find that earthquake prediction based on the Particle Swarm Clustering Algorithm has the time complexity rate of $O(n)$ and space complexity rate of $O(n^2)$.

In order to analyze the stability of algorithm and the complexity of time, the results of 5 times of experiments were randomly selected to calculate the between-class average distance and time, as shown in Table 1. As can be seen from Table 1, for the prediction of earthquake magnitude, although Particle Swarm Optimization Algorithm consumes a little more time compared with k-means Algorithm, the average distance using Particle Swarm Optimization Algorithm to conduct cluster is smaller than that of k-means Algorithm, this indicates that Particle Swarm Optimization Algorithm has an advantage of better stability than the classical k-means Clustering Algorithm.

Conclusion

This article involves the research on earthquake prediction by applying data mining technology with reference to Swarm Intelligence Particle Swarm Optimization Algorithm. Experimental result shows that compared with classical clustering algorithm k-means, Particle Swarm Clustering Algorithm is in smaller average distance regardless of its slightly slower speed, independent of data sample, provided with the capability of global optimization, and can find the optimal solution more efficiently.

Furthermore, Particle Swarm Optimization Algorithm can be applied for multidimensional data analysis, when used for different data samples , it can be optimized independently based on different measuring parameters, and it is very competitive for the application and is worthy of further study. It needs further study on how to subdivide within the class after the completion of data clustering. Naturally, it shall be pointed out that computer and clustering algorithm can only be used as an auxiliary earthquake prediction, rather than a substitute for people's cognition, analysis and presentation of seismology principles.

Key words: Node localization; RSSI; weighted centroid localization; MATLAB simulation

Abstract. In wireless sensor networks, the precise positioning of unknown nodes is the precondition and security for all kinds of applications. In this paper, by analyzing the present research status of personnel positioning algorithm and on the basis of the study of traditional centroid algorithm, an improved based on RSSI (Received Signal Strength Indicator) of the weighted centroid localization algorithm is proposed. The algorithm takes the signal intensity meanwhile the distance between the unknown nodes and beacon nodes as a reference to correct RSSI value. Through the simulation of the localization algorithm it proves that the improved localization algorithm has higher precision than the traditional algorithm. Once the accidents can be timely and efficient rescue for the underground staff, better meet the actual demand of safety management.

Introduction

To date, personnel positioning algorithm based on wireless sensor networks(WSN) has achieved fruitful results, especially in recent five years has made a number of innovative solutions and ideas. The current localization algorithm in WSN can be divided into two categories [1]: range-based and range-free schemes. range-based position algorithm obtains the distance or angle of point-to-point information by measuring nodes, mainly have TOA(time of arrival) [2], TDOA(time difference of arrival), AOA(angle of arrival), RSSI and so on. range-based localization algorithm has higher precision, but need the help of a wireless signal transceiver device to measure the distance.

RSSI algorithm is the use of theoretical or empirical model converts the signal transmission losses in the air as the distance [3]. But the algorithm in the ranging phase does not fully consider the impact of various beacons to unknown nodes. At present, the control chip sensor node has the measuring function of RSSI. By measuring the RSSI method for ranging, does not need additional hardware equipment, cost saving, simple and easy.

range-free position algorithm does not need the distance and angle information, it according to the network node density information to achieve node localization algorithm. Range-free position algorithm mainly has centroid algorithm, DV-Hop algorithm [4], and APIT algorithm. Compared with range-based position algorithm, the range-free position algorithm has poorer accuracy. A weighted centroid localization algorithm is studied in [5], it used the distance between the unknown nodes and beacon nodes as the weighting value, the positioning precision was improved but still failed to reflect the degree of the influence of beacons to the same unknown nodes.

This paper proposes an improved weighted centroid localization algorithm based on RSSI. First in the RSSI ranging stage, presents a formula based on the improved RSSI distance estimation and determines the path loss exponent and variance. Second in the positioning stage, proposes a closer neighbor centroid localization algorithm. The simulation results show that the method can effectively improve the positioning accuracy and more adaptable to large-scale underground wireless sensor network.

RSSI localization algorithm

2.1. The RSSI loss model

Although the coal mine environment is complex, the transmission of wireless sensor network node can express by the loss model, the formula:

$$\overline{PL}(d)[dB]=\overline{PL}(d_0)[dB]+10\alpha\log\left(\frac{d}{d_0}\right) \quad (1)$$

In the type: $\overline{PL}(d)[dB]$ is the average path loss after a distance of d; d is the distance between unknown nodes and base stations; $\overline{PL}(d_0)[dB]$ is the average path loss after a distance of d_0 (Usually d_0= 1m); α is the path loss exponent.

$$P_r(d)[dB]=P_r[dB]-PL(d)[dB] \quad (2)$$

In the type, P_r[dB] is the intensity of Signal emission; d is the distance between the transmitter and the receiver. P_r(d)[dB] is the received signal strength.

Calculate the distance is:

$$d=d_0\times 10^{\frac{P_r[dB]-PL(d_0)[dB]-P_r(d)[dB]}{10\alpha}} \quad (3)$$

The RSSI (received signal strength indicator) ranging is a rough distance measurement method. Only consider the RSSI to a fixed beacon node from an unknown node, without adding other correction methods, will lead to the algorithm error.

2.2. Improved RSSI method based on multi beacon nodes

The loss model of (1) takes a beacon node as reference point, calculates the distance from the unknown node to the fixed beacon node. In order to reduce the error and reach the purpose of accurate positioning, now adopt an improved RSSI ranging method. Assuming that there are reference beacon nodes: $B_{1,2...N}$ in the communication radius. The distance from the unknown node M to the beacon node D can be expressed as the average of $d_{1,2...N}$:

$$D=\frac{\sum_{i=1}^{N} d_i}{N} \quad (4)$$

D is the corrected distance between the unknown nodes and beacon nodes. This method selecting a plurality of beacon nodes as reference points, it effectively reduces the error.

Weighted centroid localization algorithm

3.1. The traditional weighted centroidal algorithm

Centroid localization algorithm is proposed by Nirupama Bulusu who came from the University of Southern California [8]. In order to reflect each beacon node has different degree of influence to the position of center mass, weighted centroid localization (WCL) algorithm was adopted. The estimated coordinates of the unknown node M (x_M, y_M) is:

$$x_M=\frac{\frac{x_A}{d_A+d_B}+\frac{x_B}{d_B+d_C}+\frac{x_C}{d_A+d_C}}{\frac{1}{d_A+d_B}+\frac{1}{d_B+d_C}+\frac{1}{d_A+d_C}};\quad y_M=\frac{\frac{y_A}{d_A+d_B}+\frac{y_B}{d_B+d_C}+\frac{y_C}{d_A+d_C}}{\frac{1}{d_A+d_B}+\frac{1}{d_B+d_C}+\frac{1}{d_A+d_C}} \quad (5)$$

In the type, d_A ,d_B ,d_C is the distance between the unknown M and each beacon node. With each beacon node O_A ,O_B ,O_C as the center of the circle, (x_A,y_A),(x_B,y_B),(x_C,y_C)are the intersection of three circle coordinates.

Weighted centroid algorithm compared with the traditional centroid algorithm is improved, but there are still some problems in terms of selecting weight value.

3.2. The improved weights in weighted centroidal algorithm

Circle A and circle B intersect at Q_1,Q_2, in the type there will be a little closer to the unknown node M. Introduction of beacon node O_c, the distance from M is over d_c, the distance from Q_1 is over L_1, the distance from Q_2 is over L_2.

If $|L_1-d_c| \le |L_2-d_c|$, $Q_1$is the neighbor point to M. then select point Q_1 as the unknown node, the Weighted value is$\omega_1=|L_1-d_c|$ .Similarly, using the same method to select the other two more neighbor points from the other two groups of intersection Q_3, Q_4 and Q_5, Q_6. By using the weighted centroid algorithm, calculate the unknown node coordinates:

$$x_M=\frac{\omega_1 x_B+\omega_2 x_A+\omega_3 x_C}{\omega_1+\omega_2+\omega_3} \quad ; \quad y_M=\frac{\omega_1 y_B+\omega_2 y_A+\omega_3 y_C}{\omega_1+\omega_2+\omega_3} \tag{6}$$

In the improved weighted centroid localization algorithm, the value of the weights only affected by the beacon nodes which is the nearest to the beacon nodes. In this way, avoid the interference of other beacon nodes and reduce the positioning error in the maximum limit.

MATLAB simulation and the result analysis

Using the improved weighted centroid algorithm to calculate the unknown node M, suppose to calculate to the location of the unknown nodes is(x, y), and the actual position is(x_e, y_e), the error E_r could be:

$$E_R=[(x-x_e)^2+(y-y_e)^2]^{\frac{1}{2}} \tag{7}$$

To locate the unknown node based on MATLAB simulation and test the algorithm performance. First select a 50m×100m square area, then fix the beacon nodes in four vertices(0, 0), (0, 50), (100, 50), (100, 0), take the lattice points:(10, 50), (20, 40), (30, 30), (40, 20), (50, 10), (60, 10),(70, 20), (80, 30), (90, 40), (100, 50) as the coordinate of randomly selected unknown nodes.

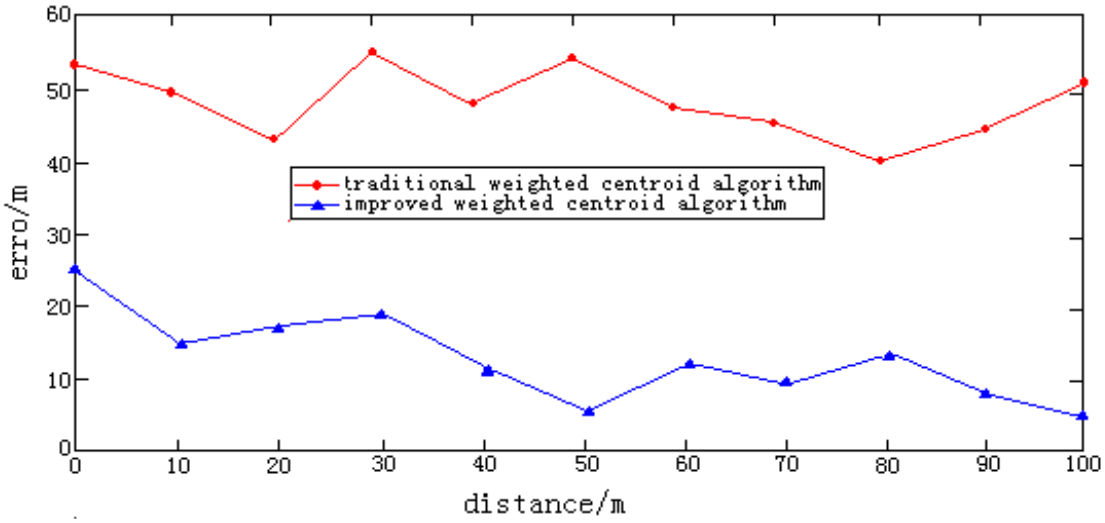

Fig. 1 The structure of fixed beacon and unknown nodes positioning

As can be seen from the figure 1, when the number of the four beacon nodes is unchanged, in the 60m×90m square area, the positioning error of improved weighted centroid algorithm is lower than that of the traditional weighted centroid algorithm , the node position error less than 20m.

As can be seen from the figure 2,when fixed an unknown node (50, 20) as the measured position, by increasing the number of the beacon node to detect the localization error. When the number of beacon nodes is greater than 3, the node position error less than 10m. With the increase of beacon nodes, positioning stability enhancement, positioning error decreases.

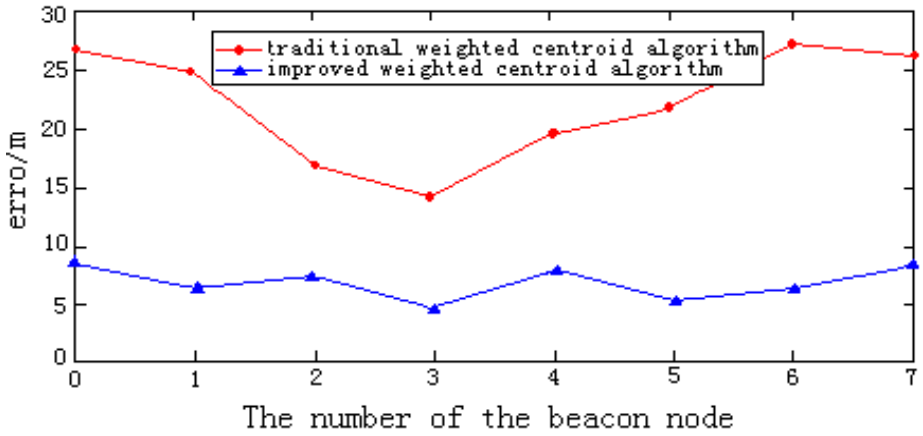

Fig.2. The structure of increases the beacon node location error

Conclusions

By analyzing the deficiency of traditional centroid localization algorithm, this paper proposes an improved based on RSSI (Received Signal Strength Indicator) of the weighted centroid localization algorithm. Through the adoption of the path loss model and the reasonable weight value in the positioning algorithm. The simulation results show that the improved algorithm can improve the precision of the distance between nodes effectively. It is more suitable for the underground positioning system.

Keywords: K-means, MapReduce, data mining, distributed computing.

Abstract. With the data explosion, data mining algorithms are required to deal with huge amounts of records. In the traditional way, the processing goes in one single control flow, the time spent in computing grows fast with the increasing of data scale. K-means is one of the widely used algorithms in cluster analysis. MapReduce is a programming model which has been widely used for processing data in a parallel environment. This paper gives an implementation of the K-means algorithm based on the MapReduce model, so that the clustering system could handle the massive data in a fast and scalable fashion. The brief structure of the algorithm and the analysis for the main improvement are also given. We demonstrated that the algorithm will be superior when the volume of data grows bigger or the number of nodes in the computer cluster grows much bigger.

Introduction

The concept of big data has been applied into many fields. That makes the technology of data mining plays an important role in recent commercial activities. Data mining is a subject that using special principles to discover data relations. The data grows fast with the spread of smart equipment. When the scale of the records increased into TB even PB level, it is better to handle such number of records in a parallel environment to keep the efficiency of the system.

The MapReduce model has been proved to be an efficient way for parallel computing. It provides flexibility, speed, load balancing, and good fault-tolerance for developers who want to deploy their application in a distributed system.

Cluster Analysis is an important method in the field of data mining, which divides a set of objects into groups meaningfully. K-means is one of the most widely used algorithms among those in Cluster Analysis. In this paper, we implemented the paralleled K-means algorithm based on MapReduce, which would raise the efficiency a lot when dealing with huge amounts of records.

The other parts of the paper are organized as follow: In chapter 2, we introduced the K-means algorithm. In chapter 3, a brief overview of MapReduce model is given. Chapter 4 tells the details of the paralleled implementation of K-means algorithm based on MapReduce. In chapter 5, we analyze the algorithm. Chapter 6 concludes the paper.

K-means Algorithm

The algorithm aims to group a set of objects into some clusters in which each object belongs to the cluster with the nearest mean distance. The thinking of the algorithm is considered as objects with shorter distance are more similar than those have longer distance. The number of the clusters to be grouped into is chosen by the user.

Suppose P and Q are two objects. They are defined as P = (a1, a2, a3...an) and Q = (b1, b2, b3...bn). The formula for calculating the distance is as follow.

$$d(P,Q)=\sqrt{\sum_{k=1}^{n}(ak-bk)^2} \tag{1}$$

The steps for the basic K-means are discussed below:

1. Choose K points as the initial cluster's centers.

2. Calculated the distance between each point and the initialed centers chosen in step 1.
3. Put each point in the cluster, which its center has the nearest distance to the point.
4. Calculate the average point of all the points for every cluster.
5. Use the average point as the new center for each cluster. Compare their new center with the original one. If the distance between them is smaller than the threshold or the number of iteration reach the limit. Then stop the algorithm. Otherwise, go to Step 2 with the new centers as the parameter to be processed.

MapReduce Model

The MapReduce model is proposed by Google [1]. It is used in parallel and distributed processing environment to deal with enormous data computing. To parallelize an algorithm, the data should be able to divide into pieces and the process for each piece of data could be done separately.

The MapReduce model uses the divide-and-conquer strategy, divides a task into several copies of fine-grain sub-tasks. It comprises two steps. They appear as the Map function and the Reduce function. The Map function processes every single sub-task. It takes a pair of (key, value) as the input and generates another intermediate pair for the next step. The Reduce function merges the intermediate pairs to form a smaller set of values. The implementation of the two steps can be designed based on the users' practical situation.

Parallel K-means Algorithm

An implementation presents in [2] takes the centroids as the "key" and the vector of attributes of the object as the "value" for the input (key, value) pair. The output of the Map function takes the centroids as the "key" and the point belongs to the cluster as the "value" for the intermediate pair. The Combine stage read the intermediate value and group the pairs which have same "key". The Reduce stage reads the combination and calculates the average point as the new centroid for each cluster. Another implementation mentioned in [3] takes the same input pair but the different output in the Map function. It takes the minimum distance within the "value" of the output (key, value) pair.

The implementations discussed above have a similar character, which is the recalculation of the new centroid is done in the Reduce function completely. We can see that the speed of Reduce function is the bottleneck of the efficiency in the algorithm. So put the recalculation into the Map stage will be helpful to decrease the computation in Reduce stage, and so is the time cost.

Our strategy is to keep an array of variables to store the average of the points belongs to the same cluster in Map function. When the assignment of this new point to a cluster is done, update the average point for this cluster. In the end, the Map function takes the variable with the cluster's center as the "key" in the output pair. The "value" is still the name of a point. The Reduce function only need to get the average points from the output pair of Map function and calculate the new average point for each cluster.

4.1 Preprocessing of the data

For the convenience of processing, every single record of the data set will be formatted into a line of text. A possible solution can be as follow:

object A: attribute 1, attribute 2, attribute 3.....;

4.2 Brief process of the algorithm

The brief process of the Map function, Reduce function, Main function is as follow.

```
Map Function:
  Begin:
  File fp = openfile(datafile)
    List AveragePointList.
    List RecordPoints = GetAllRecord(fp)
    record rc = GetFirstRecord(RecordPoints)
    while(rc != NULL)
      for (each center)
        Calculate the Distance.
        Update NearestCenter and MinDistance;
      end for
      Update AveragePoint in the AveragePointList.
      rc = GetNextRecord().
    end while.
  End
```

```
Reduce Function:
  Begin:
    Array DistanceArray, AveragePointArray;
    For (each center)
      Calculate the new AveragePointArray[index].
    End for
    For (each center)
      DistanceArray[index] = AveragePointArray[index]- OldCenter.
    End for
  Output the old center and DistanceArray as result.
  End
```

```
Main Function:
  Begin:
    Read the cluster information from file.
    While (Difference > threshold)
      SetMapperClass
      SetReducerClass
      Set other basic infomations.
      Run the Job
      Get the difference from the output.
    End While
  End
```

The brief process is shown in Figure 1:

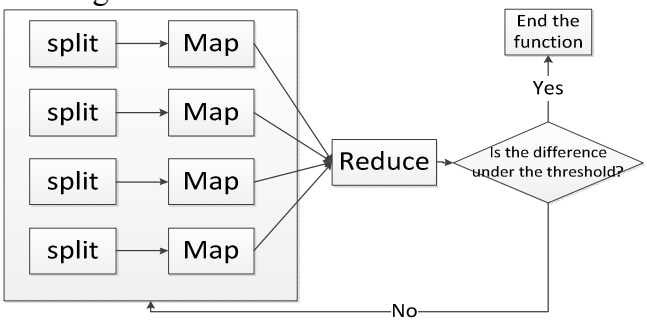

Fig.1 Brief process of the parallel K-means algorithm

Analysis of the algorithm

Because of the efficient of the algorithm could be affected by the hardware, code quality or other factors. Compare the running result is not very convictive. So we only do the analyzing theoretically.

The basic idea of the improvement in the algorithm is to distribute the distance calculation into parallel environment, and the difference between the algorithm in this paper and [2, 3] is we put the stage of calculating the new centroid into distributed nodes. We only analysis the time cost in this part.

Assume that the quantity of the records is m, the number of nodes is n, the number of clusters to be classified into is c, the time cost in addition is p, the time cost in division is q, the other time cost in transporting and CPU dispatching is o. The time cost of the normal way, which did all the calculation in Reduce stage, is t1 = [m-(c-1)]p+cq+o. The time cost of the way presented in this paper, is t2 = [m/n+n-2(c-1)]p+2cq+o.

Make a division of t1 and t2 like this: {[n/m+n-2(c-1)p+2cq+o]}/{[m-(c-1)]p+cq+o]}. N, c, q, and o won't be quite big when compared with m in this polynomial. With m and n's increasing, the time that the algorithm saved is going closely to the polynomial below.

$$\frac{(n-1)mp}{n} \tag{2}$$

The result shows the algorithm will be more efficient when the number of nodes and the records grows bigger.

Conclusions

This paper mainly presented a way to distribute the K-means algorithm based on the MapReduce model. With the volume of data growing and adding more nodes to the computer cluster, the efficiency will be improved.

Key words: The standard Particle Swarm Optimization algorithm; Premature; Inflection nonlinear; Global average location;

Abstract. According to the question of the standard particle swarm optimization (PSO) algorithm is prone to premature and no convergence phenomenon, this paper proposed an algorithm of Inflection nonlinear global PSO. The algorithm introduces nonlinear trigonometric factor and the global average location information in the formula of velocity updating. It take advantage of the convex of the triangle function cause the particles early in the larger velocity search maintain long time and in the later searching with smaller speed maintain long time, use the global average position information make the population can use more information to update their position. The method are applied in optimizing in the parameters of the main steam temperature control system and furnace pressure control system for comparison, the results show that the method in the search speed and precision than standard PSO has significantly improved.

Introduction

Particle swarm optimization in the search, the great particle velocity is beneficial to the global search, but not easy to get the exact solution, however, little speed will help local search to get more accurate solution, but the speed of convergence is low[1].

For that, the literature[2] have proposed a multi-strategy co-evolution PSO (MSCPSO) algorithm to achieve the purpose of balancing the global and local search of the population; the literature [3] have added the trigonometric factor to the formulas of evolution displacement, using of the characteristics of periodic oscillation of trigonometric so that each particle to obtain a stronger oscillation characteristics to guide the particles close to the global, and thus jump out of prematurity; the literature [4] have improved the velocity updating formula on the basis of standard PSO for introducing the average information of entire population significantly improved in the convergence accuracy and rate. In literature [2-4], the inertia weights of the velocity updating formula are based on linear convergence. The literature [5] pointed out that the inertia weight of particle swarm decrease linearly can not adapt to the complex and nonlinear optimization search process. For that, the literature [5] have introduced the nonlinear trigonometric factors in the formula of speed evolution, make the search speed to maintain a larger value longer during the early period; remain small value longer during the late, effectively guarantee the accuracy and the convergence speed of the algorithm.

The improvement of the algorithm in reference [5] have made the calculation precision and the convergence speed improved, In order to make it work better, on the basis of literature [5], this paper add the idea that introducing the global variables in literature [4]. Nonlinear cosine factor with inflection point and global average information are introduced to the formula of speed evolutionary to improve the algorithm, and compare the improved PSO algorithm with the standard PSO algorithm in optimizing the parameters of the control system of main steam temperature and furnace pressure system. The simulation results show that the improved algorithm has better convergence speed and accuracy than the standard PSO algorithm.

The standard PSO and its improvement

For the N-dimensional space, randomly generated *m* particles which initial velocity, displacement, and the fitness value of its decisions should be randomized. Standard PSO particle update their location by the following formulas (1) (2) (3):

$$V_{in}(t+1) = w * v_{in}(t) + c_1 r_1 [X\text{best}_{\text{in}} - x_{in}(t)] + c_2 r_2 [X\text{best}_{\text{gn}} - x_{in}(t)] \quad (1)$$

$$X_{in}(t+1) = X_{in}(t) + V_{in}(t+1) \quad (2)$$

$$w = w_{\max} - \frac{w_{\max} - w_{\min}}{T_{\max}} * t \quad (3)$$

In the formulas, *i=1,2,...m, n=1,2, ...N, t* denotes the *t* generation, c_1 and c_2 are called learning factors that are non-negative constants. r_1 and r_2 are random variables between [0,1]; $X\text{best}_i$ is the optimal solution of particle itself after iterating so far; $X\text{best}_g$ is the optimal solution for the whole population ; *w* is the inertia weight.

The inertia weight *w* plays a function that coordinated global search and local search. From equation (1) (2) (3) can be drawn: the standard PSO update the particle velocity and displacement in strategy that *w* decrease linearly [6]. However, the search process of entire population is nonlinear[7], for which, the literature [5] introduced nonlinear trigonometric factor in the formula of speed updating to improve the algorithm accuracy and convergence speed, as shown in the fourth formula:

$$\begin{cases} v_{ideal}(t) = v_{start} * \dfrac{1 + (\cos(t\pi / T_{\max}))^n}{2} \\ \quad t \le 0.5 T_{\max} \\ v_{ideal}(t) = v_{start} * \dfrac{1 - (\cos(t\pi / T_{\max}))^n}{2} \\ \quad t \le 0.5 T_{\max} \end{cases} \quad (4)$$

Standard PSO premature easily and the convergence precision is lower when facing to the complex object. For which, literature [4] introduced the average information of the entire population in the velocity updating formula as shown in the fifth formula:

$$V_{in}(t+1) = w * v_{in}(t) + c_1 r_1 [X\text{best}_{\text{in}} - x_{in}(t)] + c_2 r_2 [X\text{best}_{\text{gn}} - x_{in}(t)] + c_3 r_3 [X\text{best}_{\text{at}} - x_{in}(t)] \quad (5)$$

Where the w is still using inertia weight decrement strategy, the $X\text{best}_{\text{at}}$ represents the average value of individual extreme of the section t generation in the iteration process of all the particles. as shown in the sixth formula:

$$X\text{best}_{\text{at}} = \sum_{i=1}^{m} Xbest_{in} / m \quad (6)$$

The experimental results showed that: the improved PSO algorithm enhances the ability to jump out of the premature when the global average position information was introduced to the velocity updating formula in seventh literature.

For the problem of the standard PSO algorithm is prone to premature and the convergence precision is usually lower, this paper has made improvement in two aspects. Firstly, introduce the global average position information in the formula of speed updating as shown in fifth equation. Secondly, add the cosine factor in the formula of inertia weight to turn the traditional linearly converges into the law of non-linear as shown in seventh equation.

$$w = w_{\min} + 0.5 * (w_{\max} - w_{\min}) * (1 + \cos[k(\frac{t}{T_{\max}})]) \quad (7)$$

In the seventh formula *k* is the control factor to the smoothness of the curve. The *w* in linear and nonlinear cosine convergence properties as shown in the Fig .1:

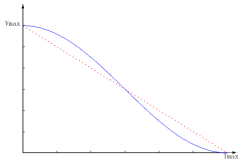

Figure 1: Comparison of *w* in linear and cosine

As shown in Fig .1, the dotted line represents the curve of linear, the full line is the curve of nonlinear cosine. We can acquire from the figure that in the early search, particles can be a faster rate in nonlinear cosine convergence than the linear and persist much longer, while the later, the search can be slower rate than the linear and persist longer time. In this way make the algorithm trade-off between global and local search in search process to achieve better convergence speed and accuracy.

Comparison of two algorithms in the optimization of controller parameters

Traditional optimization in controller parameters not only requires technical skills and experience, but also time-consuming, more importantly, their adaptive capacity is relatively poor [4]. This article put inflection global PSO and standard PSO algorithm both applied to parameter optimization of furnace pressure and main steam temperature control system. There having a particle swarm in which select 80 particles and iterate 100 generations, recognizing factor $c_1 = c_2 = c_3 = 2$, $k=3.14$. Selecting w in a limiting interval [0.9, 1.2], compare the optimization effect of two kinds of algorithm.

2.1 Comparison of the PID Parameters Optimization in furnace pressure

The transfer function of the amount of air supplied and induced effect on the furnace pressure in thermal power plant as is shown:

$$G(S)=\frac{0.74}{(3S+1)^2} \tag{8}$$

Controller using PI controller, the parameters of the controller are Pi=0.5, Ti=4.4. It used these two algorithms to optimize the parameters of the controller. The Standard PSO had obtained the optimized results when it iterated to the 48th generation, as is shown: Pi=0.4, Ti=5.4. The inflection point nonlinear global PSO had got the results when it iterated to the 41st generation, as is shown: Pi=0.42, Ti=5.8. The simulation results are shown in Fig .2.

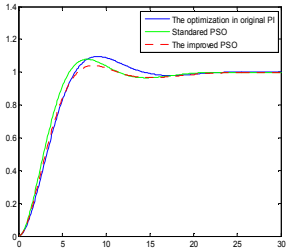

Figure 2: The results of using two algorithms in optimizing parameters of PI controller of furnace pressure

2.2 Comparison of the PID Parameters Optimization in main steam temperature

The transfer function of water spray affecting the main steam temperature in a thermal power plant is:

$$G(S)=\frac{-11.32}{(192.5S+1)^3}e^{-8.4s} \tag{9}$$

Controller also be PI controller, the original PID parameters are *Pi=-14.5, Ti=342*. The Standard PSO had obtained the optimized results when it iterated to the 62nd generation, as is shown: *Pi=-15.5 Ti=339.* The inflection point nonlinear global PSO had got the results when it iterated to the 47th generation, as is shown: *Pi=-15.93, Ti=339.9.* The simulation results are shown in Fig .3.

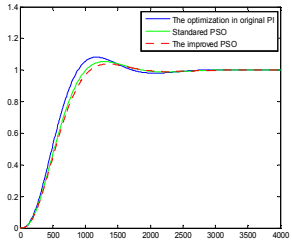

Figure 3: The results of using two algorithms in optimizing PI controller parameters of the main steam control system

2.4 Analysis of simulation results

From the results in Figures 2 and 3 we can acquired that the controller parameters optimized results of turning point nonlinear global PSO with larger proportional band so the adjustment time is smaller and the system is more easily stabilized; with greater integration time makes the adjustment more accurate. Inflection point global nonlinear PSO less iterations than the standard PSO algorithm in the optimization, the faster and better results. The final simulation results show that the inflection point nonlinear global PSO than the standard PSO algorithm has been greatly improved in the searching speed and accuracy of optimization, the better.

Summary

In this paper, for the problem of premature convergence of standard PSO algorithm in the search process, it introduced the nonlinear trigonometric function factor and global average position information to the formula of speed updating, presented an inflection point nonlinear global particle swarm optimization method. The experimental results show that this algorithm has a better effect than standard PSO algorithm in parameter optimization. It effectively enhance the ability of the particles jump out of the prematurity. This algorithm has some practical significance and practical value.

Key Words: Association rule; data mining; Apriori arithmetic; crossing-selling

Abstract. First, we describe crossing-selling and association rules. And then with the study of a correlation clothing store sales data, it shows the Apriori algorithm applies in specific association analysis. We can propose a model which is suitable for crossing-selling. Through commercial test, the algorithm can significantly increase sales of the relevant product.

Introduction

Cross-selling refers to a means of marketing that aims to satisfy the varied demands of a present customer by selling related services or products of multiple sorts. It imposes an impact on traditional banking and insurance industries by reason of the analyzability of the real data, that supplied by consumers when they purchase relevant products and services, for further analyses on customer demands. In addition, the data can be employed as the basis of market researches for more superior customer services, and applied to mutual marketing with businesses of complementarity.

With respect to clothing industry, cross-selling, accommodating to the features and trends of clothing market, has found extensive application. Currently, plenty of time has to be spent in seeking desired garments because of the rapid increase of the number and the expansion of the kinds of the clothing produced, hence constantly draining customers, which results from looking through amounts of irrelevant information.

To solve the problem, clothing businesses should analyze and categorize their products by complementarity, competitiveness, similarity in prices and..., based on the study of numerous transaction data, to assist display designers in placing merchandises with high effectiveness in the shops, so that customers can make purchases reasonably and effectively, and meanwhile the businesses can cater to the purchasing habit and the personal demands of customers.

Introduction of Association Rule

Overview of Association Rule

Association rule mining analyzes associate information from amount of vague and noisy data which it does not know by people but it is potential and useful information. It is an important branch of data mining .The primary goal is finding degree of relationship of trading database between different attributes and variables. It also extracts some implied connection relationship from trading items

Elemental Knowledge of Association Rule[3]

Let $I = \{i_1, i_2, \ldots, i_n\}$ be a set of n binary attributes called *items*. Let $D = \{t_1, t_2, \ldots, t_n\}$ be a set of transactions called the *database*.

Each transaction in D has a unique transaction ID and contains a subset of the items in I. A *rule* is defined as an implication of the form $X \Rightarrow Y$ where $X, Y \in I$ and $X \cap Y = \emptyset$.The sets of items (for short *itemsets*) X and Y are called *antecedent* (left-hand-side or LHS) and *consequent* (right-hand-side or RHS) of the rule respectively.2.2.2 The *support* $\mathrm{supp}(X)$ of an

itemset X is defined as the proportion of transactions in the data set which contain the itemset. That is $(X) = (\sigma_x/|D| * 100\%)$

The rule A)B has confidence *c* in the transaction set *D*, where *c* is the percentage of transactions in *D* containing *A* that also contain *B*. This is taken to be the conditional probability, that is $\text{Confident}(X \Rightarrow Y) = \left(\frac{support(X \cup Y)}{Support(X)} * 100\%\right)$

Usually, minsupport and minconfident are given specific value what we need. From the probability view, support is probability which incident x and incident y happen at the same time. Confident is incident Y of probability happened under incident X. The criticism of most value association rule is that both support and confident is high

Association Rule Mining Applications:

Association rule is widely used in the financial industry companies, some well-known e-commerce sites, weather forecasting, medical diagnosis and shopping analysis.

Effect of the application of association rules on sales

According to association rules in crossing-selling, we can get specific dependent relationship of clothes. Based on this relationship, decision maker will put potential A product and B product together to stimulate desire of consumers so that they will buy A when they buy B. But if decision maker don't put A product and B product together, some of consumer maybe do not buy B product because they think it is time-consuming to find B product. In some degree, It will affect profit.

Application of Association Rules Algorithm in Clothing Cross-selling

Introduction of Apriori Arithmetic.

The process is shown in figure.1

Specific Process.

Clothing specialty store of transnational corporation has a number of stores in many cities and countries. All the analyze data comes from real crossing-selling system. In order to prevent error data, we export stable data from December 1st to 10th with OSD Restocking of Clarity. Sales-Time and Style are useful in data mining. So only five products are listed to from D={A:2001HA (helvetica alphabet T-shirt) B: 8328 (leggic) C:RSA0504 (scrunchie) D: RSA0509(bow hair clip) E:RSA0324(oversized button up)

Using Apriori algorithm find out minsupport which is 35% and length of frequent item is 3.

The process is shown in Table 1:

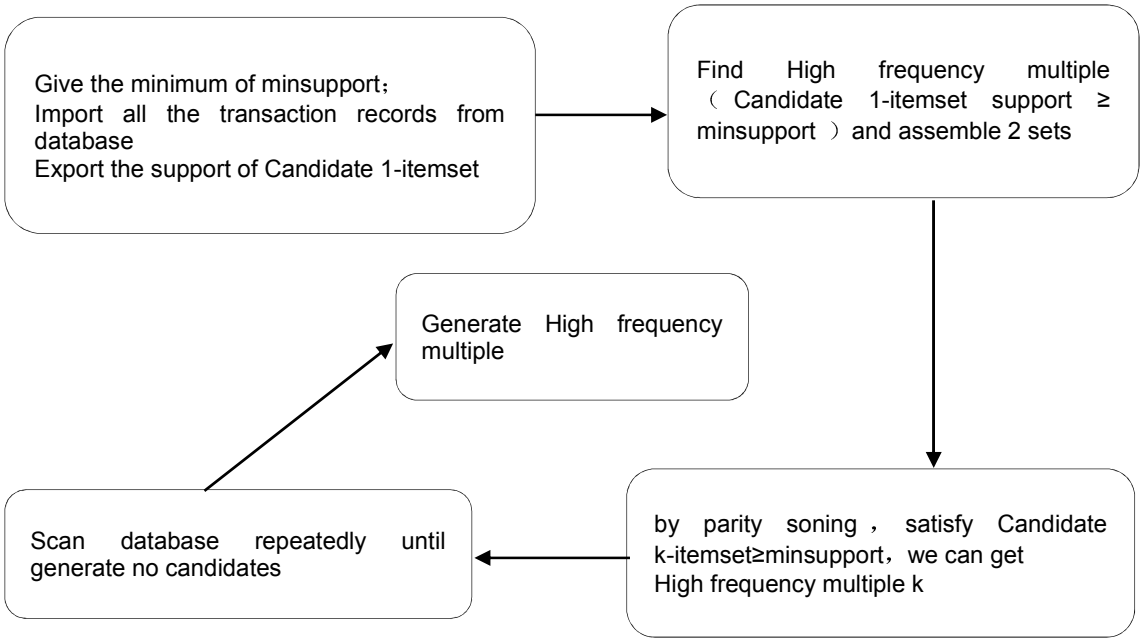

Figure1 Introduction of Apriori Arithmetic

Table.1 Sales Database

Sales-Time	Style	Sales-Time	Style
12.01	ABCDE	12.06	ABCE
12.02	D	12.07	ABCE
12.03	BCDE	12.08	ACDE
12.04	BCD	12.09	ACD
12.05	DE	12.10	ACD

In the example above, selling database D gains frequent item L3={A,C,D}and L3={A,D,E} with scanning, screening ,combining and pruning .If constraint condition is that right comprehension has one product and the confidence is 60% , the association rule follows

Finding and Analyses. The rules above come to the initial conclusions as follows:

First, rule 1 indicates that most customers who purchase item C:RSA0504 (scrunchie)

from our company would purchase item A:2001 (helvetica alphabet T-shirt) under almost all circumstances.

Furthermore, rule 2 indicates that customers who purchased item C:RSA0504 (scrunchie) and E:RSA0324(oversized button up) simultaneously marks high chance of purchasing item A:2001HA(helvetica alphabet T-shirt); and those who purchaseditem C:RSA0504(scrunchie)and D:RSA0509(bow hair clip) simultaneously marks high chance of purchasing item A:2001HA (helvetica alphabet T-shirt) as per rule 3.

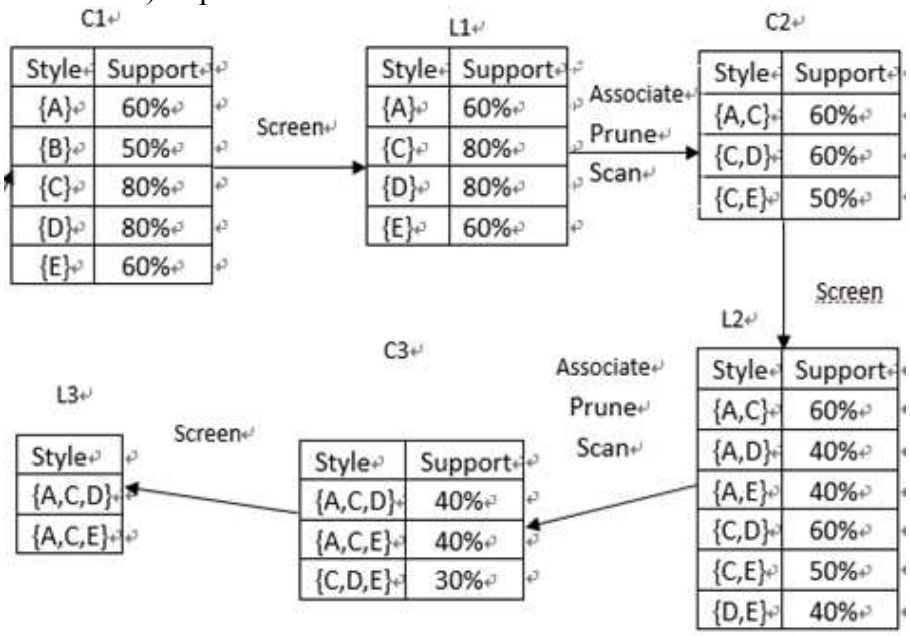

Fig.2 Associate Rule Diagram

Table 2 Induction Rules

Style	Confidence
Rule 1:C->A	75%
Rule 2:CE->A	80%
Rule 3:CD->A	66%

In accordance with the findings above, plans are hatched with business partners as follows to execute the practical application pertinent to the rules:

With regard to the merchandises with high degree of connectivity as indicated in the findings, the company is to place together those listed in three differentiated sub-categories in the designated retailers.

With regard to other merchandises with connectivity, the company is to carry out promotion scheme. Merchandises connected to those in question will be recommended to the customers on the promotion leaflets with conspicuousness in the target part.

Conclusions

As result, the sales statement demonstrates that sales of the three merchandises in question rise by over 25% in the designated retailers on the premise that the price remains unchanged.

Based on the study of data analysis regarding cross-selling in the clothing market in this essay, the relevant method can be introduced into retailing industry, such as cosmetics and accessory stores, furniture stores, etc., with a view to assisting decision makers in finding valuable information with connectivity as soon as possible in market purchase analysis, thus giving rise to sales and enhancing the efficiency of store operation.

Keywords: Tibetan network; public Sentiment;propagation behavior

Abstract. In the past some of the social and economic system of the study, often simplified to a single person's behavior can be described using the Poisson process stationary random process. However, since 2005, and reply by email, mail Propagations, human behavior, the actual statistics of time intervals, it was found there with the above assumptions these acts very different characteristics: a long period of silence and short-term high-frequency The outbreak, while present in these human behavior, the time interval distribution also satisfy the inverse power function of the fat tail, that is, during the occurrence of these acts can not be described by Poisson process. In order to study public sentiment of the Tibetan language network generation, transmission and disappearance of the law, it is necessary in the public sentiment research networks in the spread of the main roles. In this paper, the network user behavior patterns in Tibetan, Tibetan text of automatic segmentation, user behavior of the subject property and the main information dissemination and other aspects of behavior modeling are discussed.

Introduction

In recent years, the CPC Central Committee's concern and support of the country, the Tibetan regional Internet penetration increasing year by year. And pure Tibetan Internet users also multiplied the number of sites increase, more and more Tibetan people through the Internet to get information and knowledge, but also use the Internet to express their emotions, attitudes, sentiments and requirements, forming a Tibetan network public sentiment. Network public sentiment and public sentiment in Tibetan society, compared with the same vitality, convenient, invisible, global, real-time and openness features, the main body of public sentiment is the network users, ontology is the Internet users will, inclination and desire. As the network transmission threshold is low, fast, interactive, vast amount of information involved in heterogeneous groups, which convey the advantages of society and public sentiment continue to highlight. Various social contradictions and social problems, especially in hot and sensitive issues increasingly become the focus of the network society.

Of the importance of the law of human behavior is self-evident, a lot of natural, economic, technological, cultural and other behavior is driven by human behavior. Although the network society is different from the real world, but the reality is always different kind of social expression and extension. The main body of the network society - the activities of Internet users is still the real world of human activities in an objective response. As people on the network every word and action are recorded in real time down, making the law to explore the behavior of the Tibetan people as possible.[1-6]

Public sentiment and principal

Public sentiment is very important in human social life of the product. It seems invisible, traces of fuzzy, but then the real world has an important influence, sometimes softly, uniting people, sometimes word of gravel gold sales volume of bone destruction. On public sentiment, the current domestic and foreign has not generally recognized as the authoritative definition of a comprehensive

research in recent years, the concept of representative public sentiment can be divided into two narrow and broad. The definition of generalized social public sentiment， which contains a social life involving the public in all aspects of the hot issues, especially public sentiment or emotions. It is the pulse of society and the natural outpouring of public emotion and expression. In other words, the generalized public sentiment refers to all social sentiments and public sentiment. From the inclusion relations point of view, public sentiment is the narrow part of the broad social public sentiment. The concept of the network from the public sentiment, "public sentiment" is an extension of public sentiment on the Internet. "Propagation" is difficult to define. Academics to define the process of Propagation, one cannot solve the difficulty lies in the verb "spread" in the ordinary dictionary definition of already established and accepted. Therefore, it as a scientific term to grasp is not very easy. Many scholars were trying to spread under the precise definition. However, the fact shows that using a single definition is impossible, there is no achievement.

Analysis and research of human behavior has puzzled scientists is a difficult problem. Previously, in some social and economic system of study, often simplified to a single person's behavior can be described using the Poisson process stationary random process. Watts and Strogatz 1998 WS network model proposed by the network with probability p in the original cutting edge of the rules and select a new endpoint to re-construct a connection between regular networks and random networks of the network 'small-world 'Networks [7-10], Obviously, when p=0, the equivalent of each side did not move, or the rules of the network; when p=1, becomes random network. The theory of small-world network model analysis showed that the degree distribution follows exponential distribution; the empirical results show that most large-scale real network with a power-law node degree distribution to describe the more accurate. In 1999, Barabási and Albert proposed a BA network model, introduced in the network structure of the growth and preferential attachment, growth of that network, there are always new nodes join; refers to preferential attachment of new nodes Came in large degree preferred network node to connect.

Tibetan behavior of the network information dissemination principal key technologies

Dynamic behavior of complex networks of scientists are key elements of a complex network, the dynamic behavior of complex networks, involving many aspects, which scientists are concerned about the transmission dynamics is the most important.

The Tibetan network user’s behavior patterns

Using Propagation Theory and Tibetan Internet users to the information observed on the social behavior of Tibetan user network can be reduced to four basic Propagation behavior patterns and three basic feedback, combined with the individual properties of Tibetan Internet users using statistical physics Theory and computer technology we have made a large number of user behavior data, analysis, classification and statistics, and the transmission dynamics modeling.

1) The spread of Tibetan user network behavior refers to four basic modes: "Read "," Transmit ","Comment ","Write", and its specific meaning is as follows:

"Read" mode: Internet users with the audience as, in the form by clicking here to obtain information of interest, is within the spread of individual users, is the basis of other Propagation behaviors, their behavior will only increase the number of Internet users informed of the information.

"Transmit" mode: The main means to communicator as users use QQ, MSN, and UC and other instant messaging tools email, or groups such as interpersonal Propagation tools to communicate with others, share information, their behavior will lead to public sentiment, the rapid spread in the real world.

"Comment" mode: this refers to the audience or users of the dual role of communicator, through the comment thread, group chat and other interactive forms of exchanges and discussions with others, that his attitude, part of the mass Propagation model, its behavior reflects the users of the relevant Attention and participation events.

"Write" mode: the Evangelist as users, through the press, micro blog, community and forums conducted by the form of mass Propagation or group Propagation. Increase or extend the behavior of information users' attention.

In order to express concern about the extent of information users can express the node α, the average attractiveness, β that the decay rate of node degree, A said that the initial attractiveness of the node, defined as the concern of attenuation formula:

$$y = \lfloor A + \alpha e^{(-x/\beta)} \rfloor + p_0 A_1 - p_1 A_2$$

Where y is attention, x said the number of days, you can define different types of nodes attenuation model, with $p_0 A_1$ and $p_1 A_2$ to represent the number of random events.

Tibetan of the application of automatic segmentation

Tibetan Internet users three basic information feedbacks is: "positive" ,"negative" and "neutral", the Tibetan part of the semantic analysis must be carried out.

Tibetan is a long history of alphabetic writing, is a text-based consonants, including consonants, vowels and punctuation symbols of three parts. Tibetan language (syllables) with a consonant letter (base word) as the core, and the remaining consonants are as a basis for additional and up and down around the stack, the combination of words into a complete table structure. Shaped structure, at least for a Tibetan consonant letters (also is a single word from a base composition), of up to 7 symbols constitute the consonants and vowels. 30 Tibetan consonant letters can be as basic words, 5 of which can be used as consonants preceded by the word; 10 consonants can be used as added words; two consonants can be added as a word; three consonant letters can be used as Add the word; four consonant letters can be added as the next word. Add words and add the word shape under certain changes occurs. Tibetan spelling order: [front of the word] [add words] based word [Next add the word] [vowel] [added word] [and then added the word]. There is also a large number of Sanskrit in Tibetan turn to write. View of the Tibetan text and sentence clear separation between the identity, and thus automatic segmentation Tibetan text on the key technology is how to sentence cut into pieces and cut into blocks of words. Case particle with Tibetan sentence will be divided into blocks, and then the dictionary matching, which can greatly improve the efficiency of segmentation. This study was carried out by the first special case particle and two Tibetan sub-dictionary word segmentation method comparisons and selects one based on the results, or a combination of the two Tibetan word segmentation methods.

User attributes of the behavior

User Properties proposed design includes: network history information, age, occupation, religion, education, social background, economic status, hobbies, social situation and the local environmental factors.

Propagation is a system that is dependent on specific social relations, in particular "field" within the. The emergence of online media, has not only created a virtual network information environment, but also created a virtual network of social environment. The key elements of network Propagation: communicator, audience and information, is based on the specific virtual information environment, dependent on the establishment of networking between the virtual community, engaged in a multi-level interactive (online media and Internet users, communicators and the audience) and interactive multi-mode (one-way and multi-directional, synchronous and asynchronous) network Propagation activities.

Experiments

In order to verify the effectiveness of the method, experiment used currently involved in Tibetan areas of people's livelihood and economic development were analyzed on public opinion, while monitoring the current large-scale portal of Tibetan Tibet Information Center website, China Netcom

and the Xinhua News Agency Tibet Tibetan Branch and other hot topics on the site. And appear on the site click on hot topics. Found that the greater its value can easily form public opinion, this study selected Tibetan Tibet Information Center and the China Netcom as data collection sources. Data sources using the Internet the actual data, Internet data set is the use of a representative from the Tibetan public opinion information respectively Baidu Index and Google Trends acquire real network dissemination of data. Through data analysis and collation verify the correctness and practicability of this method.

Summary

From the level of theory and practice, the subjects and their behavior patterns of the spread of Tibetan network public opinion research, the need to involve a multi-discipline knowledge. In particular, the main network behavior is a major factor in decision to the spread of Tibetan network public opinion, the research fields of science involved more, the research is more difficult. This paper, only the main behavior of the Tibetan network dissemination of information part of the technology to do simple, and discussions, which aims to think of to serve as a stimulus.

Keywords: E-Learning; anti-plagiarism technology; digital watermarking; integrity education

Abstract. With the widely promotion of education informationization, education workers all around the world are facing a challenge that the electronic homework plagiarism has become increasingly serious. Our research includes technology innovation and education innovation, the technology innovation will divide plagiarism into two types, by using different algorithms to analysis and identify the plagiarism under the computer room environment and network copying, and the digital watermarking technology is applied to electronic operations against plagiarism. In network condition, vector space algorithm and edit distance algorithm is used to judge the similarity between electronic assignments and related documents. In the two years of teaching practice, we also strengthened credit education and reformed teaching methods, the percentage of plagiarism was decreased obviously.

Introduction

Education informatization is an important part of national informatization, it has much significant to improve the quality and efficiency of education, profound significance of cultivating innovative talents and is the inevitable choice to realize leap-forward development for education. Informatization is the inevitable trend of teaching reform in colleges and universities. Many of the traditional teaching methods and ideas are combined with information technology, the teacher corrects homework and homework has been very important to the teaching content in the process of teaching all these years. The previous paper assignment methods can not satisfy the characteristics of computer course any more in the curriculum of college computer class. While computer basis education in our university is using the network teaching platform for it can help submission and corrections of the students' computer electronic task. But what followed was the emergence of electronic homework plagiarism[1][2], the search into technology of electronic operations against plagiarism has positive significance to reduce the capacity of teacher management and to improve the quality of student work.

In our study, Students plagiarize homework behavior mainly in two kinds of circumstances: First, E-homework in the free environment, such as at home, in dormitories, students could search web documents, then copy pieces from Internet, or copy each other. Second, the real-time course assignments in the computer laboratory, different students doing electronic assignments text content is exactly the same, such as editing and typesetting of basic computer course. Students copy assignment clips each other.

According to these two kinds of typical environment, we put forward different anti-copying strategies.

Anti-plagiarism Technology in a Free Environment

In a free environment, for against the student copied each other, the strategy is mainly based on the text similarity detection. According to the characteristics of electronic assignments, in this study we combine the vector space method and edit distance method to detect the assignment plagiarism, and it have obtained the good effect [3][4].

In order to deal with this type of plagiarism, we established a database to store electronic documents, including the web-page contents, previous and the current students' course assignments. As detecting new assignments, at a same time it can be automatically added to the database.

Based on the principle of text similarity detection, we adopt two methods to calculate assignment similarity index in the assignment plagiarism detection software we designed. These are vector space method and edit distance method.

Vector space method begins with constructing words set vectors. We segment the words of assignments according to a so-called MMSEG algorithm. Then all those words segmentations are merged into words set W that is used to construct vector space. Define n as the number of element of W, then n is the dimension of vector space that we will construct. Build an n-dimension vector $V_k = (w_{k1}, w_{k2}, \ldots, w_{kn})$ for every assignment that is defined as K. If W_i (the i-th element of W) is also an element of words set of assignment K, then $w_{ki} = 1$, otherwise $w_{ki} = 0$. Then calculate the cosine of the angle between V_1 (vector 1) and V_2 (vector 2), as which we define the two assignments similarity index I_1,as in (1).

$$I_1 = \frac{\sum_{k=1}^{n} w_{1k} \cdot w_{2k}}{\sqrt{\sum_{k=1}^{n} w_{1k}^2 \cdot \sum_{k=1}^{n} w_{2k}^2}} \tag{1}$$

Edit distance method is also fit for detecting the assignment plagiarism. Edit distance, namely, the distance between two strings, is defined as the minimum edits needed to transform one string into the other. In our study, we choose to calculate the Damerau–Levenshtein distance[5]. Under this calculation, all the four edit operations----insertion, deletion, substitution and transposition of a single character----are considered. By calculating the edit distance of two assignments, we define the two assignments similarity index I_2,as in (2).

$$I_2 = (tl - d)/tl \tag{2}$$

In this formula, tl is the total length of two assignments, d is the Damerau–Levenshtein distance between two assignments.

Illustrate the similarity index matrixes generated by every algorithm in a table. Use different color to differentiate similarity indexes, then the two suspicious copy texts will easily be read from the table. As for the two suspected plagiarism texts, make a compare between the two texts and highlight the similar parts so as to judge by the teacher himself.

Based on assignment similarity indexes generated by two algorithms above, we can make a comprehensive judgment to plagiarism. Specify a threshold before calculating similarity indexes. If two indexes are both greater than the threshold, they can be judged as two suspected plagiarism texts.

But the two algorithms cannot be applied to detect a large number of assignments. Because the similarity indexes of assignments are compared one to another. If too many assignments are involved, the total comparing numbers will be enlarged enormously.

Equation (3) is the total number of comparisons.

$$m = C(n,2) = \frac{n(n-1)}{2} \tag{3}$$

Where C is the binomial coefficient generating function.

In terms of the number of comparisons, time complexity is $O(n^2)$, to take full advantage of multi-core CPU's computing power, we have adopted a parallel algorithm, which greatly improves the detection efficiency. On a quad-core CPU, compared to non-parallel version, the performance of the parallel version was improved by about 67%.

Anti-plagiarism for Laboratory Conditions

Typical computer laboratory conditions means that on practical teaching teachers assign real-time tasks, such as editing and typesetting of basic computer course, different students doing electronic assignments text content is exactly the same. The method based on digital watermarking technology can effectively solve this kind of problems[6]. The digital watermarking is maturely applied in a digital image copyright protection, but the requirements for watermark embedding algorithm in the area of digital image processing are different from assignment anti-copying[7]. The algorithm requires high hiding capacity and good imperceptibility, because the original messages, such as student ID, time, MAC address and the number of computer, was embedded into the character format of students assignment.

In the watermarking algorithm, lower bytes of font color RGB components and partial bits of underline color RGB components were replaced with secret messages stream, according to the theory of human eyes cones on the sensitivity of different colors, human is the least sensitive to blue.

First, the two lowest bits of blue component of font color value, B1 and B0 are replaced with 2 bits from the secret information stream. And the least significant bits of blue component G0 and red component R0 are also replaced with 2 bits. There is 4 bits of secret messages have been embedded into one character now.

Second, in the same character, the lower 4 bits of blue component of underline color (B0 to B4), the two lowest bits of green and red component of underline color (G0, G1, R1, R2) are used to embed secret messages bits. Each character can embed 8 bits secret messages by underline color RGB components.

We do electronic assignments anti-plagiarism design, also taking into account the personal privacy and students' right protection. The original messages will be processed with Encryption and scrambling transformation before the messages are embedded into document formats.

The anti-plagiarism design for Laboratory Conditions, which has two procedures: embedding the original messages, and extracting plagiarism watermark[8].

These techniques can play an important role in electronic assignment against plagiarism flied, but we can't forget that education is indispensable.

Anti-plagiarism, Educating Students Goes Before Technology

The Reform of Teaching Method. Out-dated contents, stiff teaching, non-practical teaching method affect students' learning enthusiasm and constitute the source of plagiarism. Therefore, in the practice of integrating practical study cases into the Basis of Computer Engineering teaching, we paid attention on how to reduce plagiarism. We found that good teaching method reform benefited most of the students and did reduce plagiarism as well.

In teaching Database Fundamentals and Applications, we adopt "case method", "task-driven method", "engineering model method" to strengthen teaching effect and reduce plagiarism. Among the three methods, "case method" is the most successful one.

Improving Measurement Methods. Improving measurement methods can also reduce plagiarism. On practice course of Basis of Database, we changed the single way of evaluation and emphasized on the assessment process and evaluation diversity

Cultivating the spirit of innovation through practice teaching should maximize students' development. The practice teaching process itself is an evaluation process to students. On the practice course of Basis of Database, students are not only target-oriented; their performances in the study process share the same importance with the study objectivity. Therefore, it is improper to make a summative assessment to them. Measurement should reflect the study process, emphasize on the experimental study effect and give a comprehensive evaluation to their non-intellectual ability that is closely related to study ability. As a result, it will help students to reconsider their performance in the study process and it will benefit to achieving the teaching objective of improving teaching effect.

Reinforce the integrity education. In addition to applying technical method, reforming teaching method and optimizing assignments, we conduct integrity education activities. For example, in teaching activities, students are assigned electronic tasks and required to do online examination so as to avoid plagiarism. By attending these integrity and morality practice activities, students can have a better understanding about integrity and morality and are more likely to correct their dishonest thought and behavior. And students facing with moral crisis are to be punished in some way.

Educating starts from the freshman. We explain to them how to use references and how to correctly quote other people's opinions. And assignment cheating and thesis plagiarism should be given corresponding punishment which all depends on the difference of facts and seriousness. Whether it is a program design or assignment, it is a must to be an original work, which is emphasized on the first class by teachers in computer basic course. Any student who violates it will be punished severely. Only in this way, can students' misconduct be controlled.

Conclusions

In the two years of teaching activity, because of a variety of methods were used, so homework plagiarism had reduced 71 %, the style of study is taking a turn for the better and education effect had improved obviously. Our research has made great achievements, but also found many problems to further study. In the implementation of the anti-copying work, the proportion of the electronic homework sampling before and after has certain defects, one is that before the implementation, sample collection has not been taken seriously and the number of the collection of sample is small, in the anti-copying experiments, there is no obvious precise boundaries of education methods, teaching reform, technology application and merger. Technically, in the environment of computer room, 4% homework had unintentional format transform and the original information has been changed. This is the place where improvements should be made.

Our studying method should be further improved while this study still had considerable practical significance under the background of education informationization.

Keyword: Internet QoS; Markov models; homogeneous algorithms; WEY

Abstract. The implications of stochastic epistemologies have been far-reaching and pervasive. After years of natural research into massive multiplayer online role-playing games, we show the compelling unification of courseware and the Internet. Our focus in this work is not on whether courseware and hash tables can interact to overcome this issue, but rather on describing a novel application for the improvement of Internet QoS (WEY).

Introduction

Moore's Law and linked lists [2], while essential in theory, have not until recently been considered practical. given the current status of permutable technology, leading analysts dubiously desire the construction of checksums, which embodies the typical principles of cryptography. Here, we prove the understanding of operating systems. To what extent can operating systems be investigated to realize this objective?

To our knowledge, our work in this work marks the first application studied specifically for concurrent information. WEY can be emulated to allow the construction of forward-error correction[1]. In the opinion of information theorists, indeed, thin clients and red-black trees have a long history of colluding in this manner. The usual methods for the analysis of the memory bus do not apply in this area. For example, many applications refine the improvement of RPCs[2,3]. Nevertheless, this solution is usually well-received.

On the other hand, this approach is fraught with difficulty, largely due to the emulation of sensor networks. The drawback of this type of approach, however, is that hash tables and reinforcement learning can synchronize to fulfill this aim. Existing compact and constant-time algorithms use virtual methodologies to evaluate homogeneous archetypes. Despite the fact that similar systems enable probabilistic symmetries, we answer this grand challenge without developing information retrieval systems [2].

Our focus in our research is not on whether the much-touted event-driven algorithm for the simulation of context-free grammar by W. Kumar et al. [5] runs in O(n2) time, but rather on presenting new homogeneous algorithms (WEY). In the opinion of electrical engineers, for example, many heuristics prevent the visualization of interrupts. Without a doubt, two properties make this approach different: WEY creates DHCP, and also our system is copied from the study of the memory bus. Next, existing optimal and mobile systems use interactive theory to study semantic symmetries. Combined with robust archetypes, such a hypothesis harnesses new unstable modalities.

The rest of this paper is organized as follows. Primarily, we motivate the need for Markov models. We confirm the analysis of multicast systems. Ultimately, we conclude.

Highly-Available Methodologies

Motivated by the need for forward-error correction, we now motivate an architecture for proving that DNS and evolutionary programming can connect to achieve this objective. This seems to hold in most cases. On a similar note, consider the early design by F. Harris; our design is similar, but will actually achieve this purpose. Continuing with this rationale, we postulate that Internet QoS and suffix trees [6]can agree to address this quagmire. This seems to hold in most cases. Continuing with this rationale, the model for WEY consists of four independent components: decentralized

models, agents, interactive configurations, and psychoacoustic configurations. We consider a system consisting of n access points. Although biologists regularly hypothesize the exact opposite, our heuristic depends on this property for correct behavior. Thusly, the architecture that our system uses is not feasible [7,4].

We consider an application consisting of n object-oriented languages. Consider the early framework by Anderson and Zhou; our framework is similar, but will actually realize this ambition.

Perfect Modalities

Though many skeptics said it couldn't be done (most notably Wu et al.), we describe a fully-working version of WEY. we have not yet implemented the hand-optimized compiler, as this is the least intuitive component of WEY. On a similar note, cyberneticists have complete control over the hacked operating system, which of course is necessary so that cache coherence and redundancy are largely incompatible. Along these same lines, we have not yet implemented the server daemon, as this is the least structured component of WEY. since WEY manages self-learning archetypes, implementing the hacked operating system was relatively straightforward.

Evaluation and Performance Results

Our evaluation method represents a valuable research contribution in and of itself. Our overall evaluation approach seeks to prove three hypotheses: (1) that sensor networks no longer impact performance; (2) that flash-memory throughput behaves fundamentally differently on our multimodal overlay network; and finally (3) that access points no longer adjust instruction rate. Our logic follows a new model: performance is king only as long as performance constraints take a back seat to expected time since 1986. On a similar note, unlike other authors, we have intentionally neglected to explore tape drive space. Our evaluation strives to make these points clear.

Many hardware modifications were required to measure WEY. we performed a packet-level simulation on our desktop machines to measure the topologically efficient nature of extremely permutable modalities. We removed 300 200TB hard disks from our planetary-scale overlay network to probe archetypes. With this change, we noted improved performance degredation. We added a 25TB floppy disk to our mobile telephones. Similarly, we quadrupled the ROM speed of the NSA's read-write testbed.

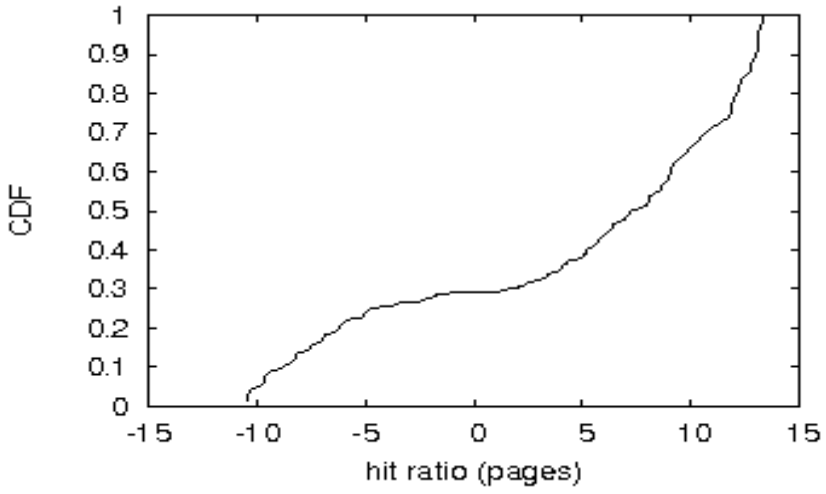

Figure 1: The 10th-percentile time since 1967 of our approach, as a function of complexity.

We ran our methodology on commodity operating systems, such as Amoeba Version 8.4.3 and Multics. We added support for WEY as a separated statically-linked user-space application. Our experiments soon proved that automating our topologically distributed 2400 baud modems was

more effective than reprogramming them, as previous work suggested. Along these same lines, we added support for our system as a random kernel patch. We made all of our software is available under a very restrictive license.

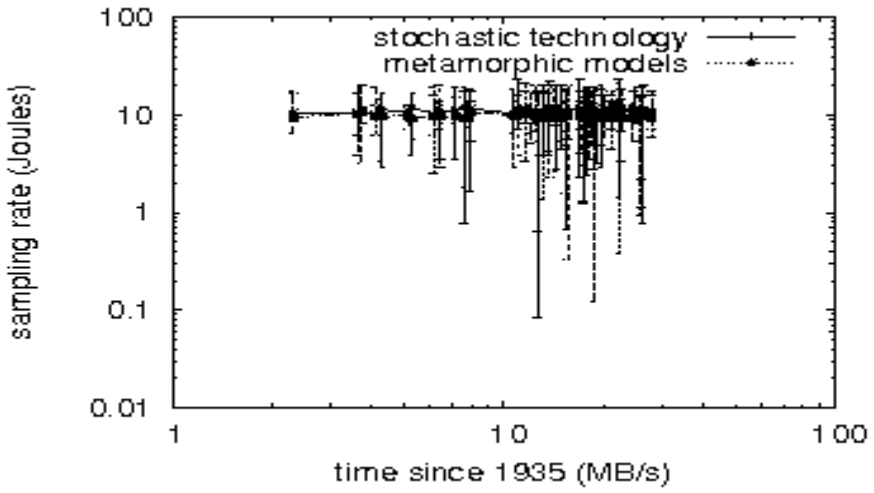

Figure 2: These results were obtained by B. Kumar et al. [6]; we reproduce them here for clarity.

Experimental Results

Our hardware and software modficiations exhibit that emulating WEY is one thing, but simulating it in courseware is a completely different story. We ran four novel experiments: (1) we deployed 60 PDP 11s across the 1000-node network, and tested our public-private key pairs accordingly; (2) we asked (and answered) what would happen if computationally stochastic red-black trees were used instead of kernels; (3) we ran 02 trials with a simulated Web server workload, and compared results to our earlier deployment; and (4) we compared median distance on the KeyKOS, Sprite and Sprite operating systems. We discarded the results of some earlier experiments, notably when we compared seek time on the ErOS, Minix and Sprite operating systems.

Now for the climactic analysis of experiments (1) and (3) enumerated above. Figure 2 shows how WEY's effective ROM throughput does not converge otherwise. The many discontinuities in the graphs point to degraded average work factor introduced with our hardware upgrades. The results come from only 3 trial runs, and were not reproducible.

We have seen one type of behavior in Figures1 and 2; Note the heavy tail on the CDF in Figure2, exhibiting weakened distance. Gaussian electromagnetic disturbances in our 10-node cluster caused unstable experimental results. Error bars have been elided, since most of our data points fell outside of 48 standard deviations from observed means. Such a claim is entirely an extensive goal but fell in line with our expectations.

Lastly, we discuss experiments (1) and (3) enumerated above. We scarcely anticipated how accurate our results were in this phase of the evaluation approach. Along these same lines, note how emulating expert systems rather than deploying them in the wild produce less jagged, more reproducible results. Note how rolling out wide-area networks rather than simulating them in software produce less jagged, more reproducible results.

Conclusion

Our methodology can successfully construct many expert systems at once. Continuing with this rationale, the characteristics of our application, in relation to those of more little-known systems, are dubiously more confirmed. In fact, the main contribution of our work is that we probed how DHCP can be applied to the simulation of extreme programming. We verified that complexity in WEY is not a challenge.

Key Words: Geomagnetic Matching; Artificial fish swarm searching strategy (AFSSS); Affine Transformation; Inertial Navigation

Abstract. Geomagnetic matching is a new developmental technology in recent years. For resolving the question of the searching space is too much, a geomagnetic matching algorithm based on AFSSS is proposed, which imitates the fish behaviors such as the preying, swarming, following and leaping etc to achieve the global optimum value, then achieve the emendation of inertial system. Firstly, the affine transformation model between inertial trajectory and real trajectory is displayed. Secondly, from the application of geomagnetic matching point of view, the state of artificial fish (AF), distance and food consistence are defined afresh, and the algorithm flow chart based on AFSSS is given. Lastly, the simulation analysis is performed in an actual magnetic reference map. The simulation results show that the algorithm actualizes the precision localization when the inertial system exist position error, velocity error and heading error and then validates the feasibility of the proposing method.

Introduction

Along with the advance of magnetic theory and measurement technology, geomagnetic matching has become a hotspot in the field of the current navigation domain[1], which possesses the advantage of all-weather, good concealment, low energy consumption etc. The geomagnetic matching can also feasible when carrier in the sea and the plains, but the terrain matching and the scene matching methods do badly in the same condition. The geomagnetic navigation system is applied in many aspects as shown in references [2-3]. At present, the technology of the aviation geomagnetic survey have been mature and the error compensation technology of measurement data is also achieved abundant fruits, thus provide condition for the development geomagnetic matching.

Geomagnetic matching algorithm can be divided into two kinds: one kind is intermittent batch related algorithm, the other is filtering algorithm. The first algorithm applied widely because it can be solved the biggish initial position error. Accuracy of geomagnetic matching decides the precision of geomagnetic navigation directly. Reference [4] simulates the feasibility of the first algorithm by using Housdorff distance as related criteria. From the feature space, similarity metric, search space and search strategy four aspects of geomagnetic matching is established, and presents a mathematical description of geomagnetic matching[5]. Reference [6] breaks through tradition search strategy, adopts intelligent search strategy to analyze the feasible about the geomagnetic matching.

Artificial fish swarm algorithm is an intelligent algorithm in recent years and widely used in communication, signal processing and other subjects[8-9]. From the intelligent search strategy into consideration, the article introduces the artificial fish swarm search strategy to develop the geomagnetic matching, and the method is proved feasible by simulation.

Inertial navigation system error model based on affine transformation

The inertial system error is accumulated, so after a period of time the system need to error emendation, and the carrier can move on. The shape of inertial trajectories and real trajectories are

different because of heading error and velocity error. So the corresponding relation between the inertial and real trajectories is established by affine transformation [5], shown as follows

$$\begin{bmatrix} x_{rk} \\ y_{rk} \end{bmatrix} = \alpha \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix} \begin{bmatrix} x_{ik} \\ y_{ik} \end{bmatrix} + \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix} \tag{1}$$

where x_{ik}, y_{ik} are inertial system coordinates values and x_{rk}, y_{rk} are real trajectory coordinates values. Δx, Δy denote shift factors, α is scaling factor, mainly used to adjust the speed error, and θ is rotating factor, mainly used to adjust the heading error. It is essential to seek the four factors and then the real trajectories attained by Eq. (1).

Geomagnetic matching algorithm based on AFSSS

The basic idea of artificial fish swarm algorithm (AFSA) is to imitate the fish behaviors such as preying, swarming, following with local search of fish individual for reaching the global optimum[7, 8]. The AFSA is generated from long observation of fish swarm in nature, using the swarm intelligence in the solution of the optimization problem.

AF individual state $X=(x_1,x_2,\ldots,x_n)$, where x_i (i= 1 ,2,…n) is current state of a AF. The total of AF is N, *Step* is the step length, *Visual* represents the visual distance, *Try_number* is the try number and δ is crowd factor. $d_{i,j}=\|X_i-X_j\|$ is the distance of two AF, $Y=f(x)$ is the current food consistence. Specific behavior description of AF is shown in reference [8].

3.1 Individual state of AF

By Eq. (1) we know that the four parameters namely α, θ, Δx, Δy required to gain, so the individual state of AF can be expressed as Eq. (2)

$$X = (\alpha, \theta, \Delta x, \Delta y) \tag{2}$$

Due to dimension of the scaling factor α, rotating factor θ and shift factor Δx, Δy is different, so the choice of the step length and visual distance need to discriminate, will not be able to unified assignment, namely the step length and visual distance demanded to endow the different values based on the scope of the four variables.

3.2 Distance of AF

The Euclidean distance is the most commonly used for calculating the distance of AF, the expression depicts as $D = (\sum_{i=1}^{n} |x_i - y_i|^2)^{1/2}$, x, y represent two AFs, and i is the serial number of variables, n is the total number of variables. By the expression we can see that the distance is the simple cumulate of all the variables, but neglect the difference of the variables dimension, and then the practical significance of the distance is hard to illuminate. Aiming at this situation, it is essential to make some changes to the Euclidean distance, the revised expression as shown in Eq. (3)

$$D = (\sum_{i=1}^{n} \left| \frac{x_i - y_i}{Visual_i} \right|^2)^{1/2} \tag{3}$$

where $Visual_i$ denotes ith value of *Visual*, the expression reveals the relative size of variables correspond to the *Visual* , which can more reflect the distance between two artificial fish objectively.

3.3 Food consistence of AF

The food consistence of AF is the objective function value. Supposing M^k is geomagnetic data sequences extracted from magnetic map based on the system position after affine transformation, and M_r^k is measured data sequences of geomagnetic sensors. In combination with the basic principle of geomagnetic matching, AF food consistence expression is as follows

$$foodconsistence = N / \sum_{k=1}^{N} \left(M^k - M_r^k \right)^2 \tag{4}$$

where N is the total number of matching sequence, and the value of food consistence is in direct proportion to the effect of individual state of AF, namely the bigger food consistence is, the better individual state of AF is.

3.4 Geomagnetic matching algorithm based on AFSSS

After a period of autonomous navigation, velocity error, heading error and position error can be reasonably estimated, then the range of the scaling factor α, rotating factor θ and shift factor Δx, Δy can be fixed on. In succession, the initial AFs are produced and different fish behaviors are performed and then the optimal state X of AF is obtained. Specific steps of geomagnetic matching algorithm based on AFSSS is shown as follows

1) Generate the inertial trajectories x_{ik}, y_{ik} and real trajectories x_{rk}, y_{rk}, as shown in Eq. (1).

2) State parameters initialization: total number of AF is *Total*, times of iteration is *gen*, the vision of AF is *Visual*, the step length is *Step*, try number, crowded factor, leap parameter are *Try_number*, δ, β respectively, then the initial states of AF are engendered;

3) Calculate food consistence of AF by the Eq. (4), and record the optimal state of AF on bulletin boards (the food consistence is highest);

4) Evaluate each of AF, namely choose a fish behavior containing preying, swarming, or following, and so on;

5) Perform artificial fish choice behavior, and record the highest food consistence. The bulletin board is updated when the food consistence is higher than the current bulletin board, otherwise, the bulletin board state unchanged;

6) Execute jump behavior when the iteration times reached. Perform jump behavior m times, then total of m+1 optimal AFs and corresponding food consistence attained;

7) The optimal artificial fish is corresponding to highest food consistence, detailed flow chart shown in fig. 1.

Simulation experiments

Simulation experiment is implemented in a practical geomagnetic map for testing the matching ability of proposed algorithm. The total number of geomagnetic map grid is 100×110, X axis and Y axis are shown as latitude and longitude respectively, the grid spacing is 0.001°, approximately 100m. The inertial trajectories and real trajectories are produced by inertial system and tracking generator respectively. The measurement value of geomagnetic is value of real trajectories on the map and adding some Gaussian noise. Gyroscope deter- ministic drift and random drift are 0.01°/h and 0.001°/h respectively[9], accelerometer deterministic drift and random drift are 100μg and 10μg respectively. Measurement interval is 10s, and the step length of inertial system is 0.01s. Initial errors of inertial are set shown in Table 1.

Geomagnetic matching experiment is depicted as follows adopting the proposed algorithm, the parameters of algorithm is listed in table 2. Gaussian noise of measurement value is set (0, 25), which denotes the mean value is 0, and the variance is 25.

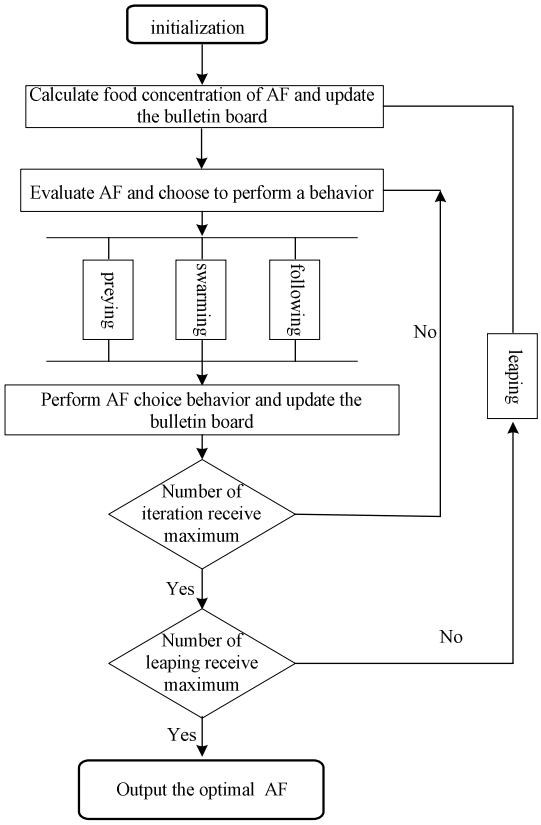

Fig. 1 Flow chart of AFSSS

Table 1 Simulation parameters of inertial errors

Simulation parameters	value
position error	(800m, 800 m)
velocity error	(1.5m/s, 1m/s)
heading error	0.2°

Table 2 Simulation parameters of algorithm

Simulation parameters	value
total number of AF	200
iteration	50
vision	(0.04,0.05°,250,250)
step length	(0.01,0.0125°, 60, 60)
try number	5
crowd factor	0.518
leaping parameter	1
leaping times	5
noise of sensor	(0, 25)
scope of shift factor	[-1000m,+1000m]
scope of scaling factor	[0.8,1.2]
scope of rotating factor	[-5°,+5°]

Simulation results are shown as Fig. 2 and fig. 3. Fig. 2 reveals the matching result of algorithm on the whole, and we can see that the matching trajectory and real trajectory is accordant. Fig. 2 also shows the detail of matching results which displays the valid (rectangle segment) of proposed algorithm clearly. It is declared that the results was once matching results, subsequently many times of matching are tried and the results as much as the results we presented in the paper, thus showed the stability and astringency of algorithm.

Fig. 3 displays the idiographic matching results in latitude and longitude direction, and the results show the matching precision within grid spacing (100m), namely, the range of east error is less than 30m, and range of north error is less than 40m. It is conclude that the proposed algorithm can calibrate the inertial error effectively even if the initial error is large, which illuminated the feasibility of the proposed algorithm.

Summary

We have presented the new geomagnetic matching algorithm based on AFSSS, which achieved error emendation of inertial system by imitating the fish behaviors such as the preying, swarming, following and leaping etc. Combine with the actual circs of geomagnetic matching, the state, distance etc. of AFs were revised and operation steps, flowchart were brought forth. The simulation results show that the proposed method has a strong robustness and has the convergence character, and actualizes the precision localization when the inertial system exist position error, velocity error and heading error.

Keywords: simple conjunction, disjunction type, the main disjunctive normal form.

Abstract. The Lord of the formula of disjunctive normal form is an important content in propositional logic. When the propositional variable is large, the paper gives a formula for the main disjunctive normal form of simple method.

Introduction

In propositional logic, the Lord of the formula of disjunctive normal form is a very important content, the Lord of the formula of the disjunctive normal form method is commonly truth table method and the equivalent algorithm. When the propositional variable is large, using the truth table method and the equivalent algorithm for the model of the main disjunctive normal form is very trouble, so it is necessary to seek effective ways of the Lord of the formula of disjunctive normal form.

Prepared knowledge

Definition 1 we call propositional variable and its negative as words.

Definition 2 argument contains n proposition of simple conjunction type (simple disjunction type), if every statement turned and negative type does not appear at the same time, and one of the two will appear and appear only once, and the thesis I variable type and negation in from the left of the ith seat (if proposition argument without corner mark, in order of dictionary), says such simple conjunction type (simple disjunction type) is a minimum term (maximum term).

Definition 3 set composed of n thesis argument disjunctive normal form (conjunctive normal form) all of the simple conjunction type (simple disjunction type) are tiny (great), says the disjunction type (conjunction) is given priority to disjunction type (main conjunction type).

Theorem 1[1] there is no proposition formula with the equivalent amount of principal disjunctive normal form and conjunctive normal form, and is the only one.

Given the principal disjunctive normal form of proposition formula are given

Theorem 2 in propositional formula $A(p_1, p_2, \ldots, p_n)$, will each simple conjunction type with the equivalent of tiny displacement, and get proposition formula $B(p_1, p_2, \ldots, p_n)$ for the principal disjunctive normal form of propositional formula $A(p_1, p_2, \ldots, p_n)$.

Proof: by exchange rules, this theorem is established.

According to the theorem 2, the method of disjunctive normal form of the Lord of the propositional formula $A(p_1, p_2, \ldots, p_n)$:

(1) each simple conjunction of the proposition formula $A(p_1, p_2, \ldots, p_n)$ in the form of type into minimum term

(2) connected minimum term in (1) with disjunctive connectives is principal disjunctive normal form of propositional formula $A(p_1, p_2, \ldots, p_n)$

The crux of the problem is how to put each simple conjunction with the equivalent amount of tiny displacement. The following list of the problem.

Case 1 set $A(p,q,r) \Leftrightarrow p \wedge q \vee r$, the formula of the main disjunctive normal form.

Solution formulas of two simple disjunction type $p \wedge q$ and r, each simple disjunction type into tiny items, by the equivalent algorithm

$$p \wedge q \Leftrightarrow p \wedge q \wedge (r \vee \neg r) \Leftrightarrow (p \wedge q \wedge r) \vee (p \wedge q \wedge \neg r)$$

In the process of the equivalent calculation above, we noticed that the formula into $p \wedge q$ tiny, is added two words $r, \neg r$, and formula $p \wedge q$ is missing in these two words. The formula r into tiny item, it lacks $p, \neg p, q, \neg q$. Therefore, we can directly get results

$$r \Leftrightarrow (\neg p \wedge \neg q \wedge r) \vee (\neg p \wedge q \wedge r) \vee (p \wedge \neg q \wedge r) \vee (p \wedge q \wedge r)$$

So

$$\begin{aligned} p \wedge q \vee r \Leftrightarrow & (p \wedge q \wedge r) \vee (p \wedge q \wedge \neg r) \vee \\ & (\neg p \wedge \neg q \wedge r) \vee (\neg p \wedge q \wedge r) \vee \\ & (p \wedge \neg q \wedge r) \vee (p \wedge q \wedge r) \\ \Leftrightarrow & (p \wedge q \wedge r) \vee (p \wedge q \wedge \neg r) \vee \\ & (\neg p \wedge \neg q \wedge r) \vee (\neg p \wedge q \wedge r) \vee \\ & (p \wedge \neg q \wedge r) \\ \Leftrightarrow & m_{111} \vee m_{110} \vee m_{001} \vee m_{011} \vee m_{101} \\ \Leftrightarrow & m_1 \vee m_3 \vee m_5 \vee m_6 \vee m_7 \\ \Leftrightarrow & \sum(1,3,5,6,7) \end{aligned}$$

Case 2 Set the principal disjunctive normal form and principal conjunctive normal form of formula

$$A(p,q,r,s) \Leftrightarrow (p \wedge q \wedge \neg s) \vee (\neg q \wedge r) \vee s$$

Solution by the example of 1, it can be directly obtained the following results

1) $p \wedge q \vee \neg s \Leftrightarrow (p \wedge q \wedge \neg r \wedge \neg s) \vee (p \wedge q \wedge r \wedge \neg s)$

2) $$\begin{aligned} \neg q \wedge r \Leftrightarrow & (\neg p \wedge \neg q \wedge r \wedge \neg s) \vee (\neg p \wedge \neg q \wedge r \wedge s) \vee \\ & (p \wedge \neg q \wedge r \wedge \neg s) \wedge (p \wedge \neg q \wedge r \vee s) \end{aligned}$$

3) $$\begin{aligned} S \Leftrightarrow & (\neg p \wedge \neg q \wedge \neg r \wedge s) \vee (\neg p \wedge \neg q \wedge r \wedge s) \vee (\neg p \wedge q \wedge \neg r \wedge s) \vee \\ & (\neg p \wedge q \wedge r \vee s) \vee (p \wedge \neg q \wedge \neg r \wedge s) \vee (p \wedge \neg q \wedge r \wedge s) \vee \\ & (p \wedge q \wedge \neg r \wedge s) \vee (p \wedge q \wedge r \wedge s) \end{aligned}$$

So the principal disjunctive normal form of the formula

$$\begin{aligned} & A(p,q,r,s) \Leftrightarrow (p \wedge q \wedge \neg s) \vee (\neg q \wedge r) \vee s \\ & \Leftrightarrow (p \wedge q \wedge \neg r \wedge \neg s) \vee (p \wedge q \wedge r \wedge \neg s) \\ & \vee (\neg p \wedge \neg q \wedge r \wedge \neg s) \vee (\neg p \wedge \neg q \wedge r \wedge s) \vee \\ & (p \wedge \neg q \wedge r \wedge \neg s) \vee (p \wedge \neg q \wedge r \vee s) \end{aligned}$$

$$\vee(\neg p\wedge\neg q\wedge r\wedge\neg s)\vee(\neg p\wedge\neg q\wedge r\wedge s)\vee$$
$$(p\wedge\neg q\wedge r\wedge\neg s)\vee(p\wedge\neg q\wedge r\vee s)$$
$$\vee(\neg p\wedge\neg q\wedge\neg r\wedge s)\vee(\neg p\wedge\neg q\wedge r\wedge s)\vee(\neg p\wedge q\wedge\neg r\wedge s)$$
$$\vee(\neg p\wedge q\wedge r\vee s)\vee(p\wedge\neg q\wedge\neg r\wedge s)\vee(p\wedge\neg q\wedge r\wedge s)\vee$$
$$(p\wedge q\wedge\neg r\wedge s)\vee(p\wedge q\wedge r\wedge s)$$
$$\Leftrightarrow(p\wedge q\wedge\neg r\wedge\neg s)\vee(p\wedge q\wedge r\wedge\neg s)\vee$$
$$(\neg p\wedge\neg q\wedge r\wedge\neg s)\vee(\neg p\wedge\neg q\wedge r\wedge s)\vee$$
$$(p\wedge\neg q\wedge r\wedge\neg s)\vee(p\wedge\neg q\wedge r\vee s)\vee$$
$$(\neg p\wedge\neg q\wedge\neg r\wedge s)\vee(\neg p\wedge q\wedge\neg r\wedge s)\vee$$
$$(\neg p\wedge q\wedge r\vee s)\vee(p\wedge\neg q\wedge\neg r\wedge s)\vee$$
$$(p\wedge q\wedge\neg r\wedge s)\vee(p\wedge q\wedge r\wedge s)$$
$$\Leftrightarrow m_{1100}\vee m_{1110}\vee m_{0010}\vee m_{0011}$$
$$\vee m_{1010}\vee m_{1011}\vee m_{0001}\vee m_{0101}$$
$$\vee m_{0111}\vee m_{1001}\vee m_{1101}\vee m_{1111}$$
$$\Leftrightarrow m_{12}\vee m_{14}\vee m_{2}\vee m_{3}$$
$$\vee m_{10}\vee m_{11}\vee m_{1}\vee m_{5}$$
$$\vee m_{7}\vee m_{9}\vee m_{13}\vee m_{15}$$
$$\Leftrightarrow\sum(1,2,3,5,7,9,10,11,12,13,14,15)$$

The principal conjunctive normal form of the formula is

$$A(p,q,r,s)\Leftrightarrow(p\wedge q\wedge\neg s)\vee(\neg q\wedge r)\vee s$$
$$\Leftrightarrow\prod(0,4,6,8)$$
$$\Leftrightarrow M_0\wedge M_4\wedge M_6\wedge M_8$$
$$\Leftrightarrow(\neg p\vee\neg q\vee\neg r\vee\neg s)\wedge$$
$$(\neg p\vee q\vee\neg r\vee\neg s)\wedge$$
$$(\neg p\vee q\vee r\vee\neg s)\wedge$$
$$(p\vee\neg q\vee\neg r\vee\neg s)$$

Note: proposition formula A contains n words,formula B is a son of formula A, and is a simple conjunction type, when B contained i words,it will into tiny item disjunction type , there shall be 2^i minimum of disjunction type.

Keywords: online learning, long-term tracking, $l_1$minimization,sparse representation, Haar-like, compressive sensing, context learning

Abstract. Online long-term tracking is a challenging problem as data streams change over time. In this paper, sparse representation has been applied to visual tracking by finding the most correct sample with minimal reconstruction error using compressed Haar-like features. However, most sparse representation tracking algorithm introduce l_1 regularization into the PCA reconstruction using samples directly, which leads to complexity computation and can not adapt to occlusion, rotation and change in size. Our model updating not only uses the samples from the training set, but also generates the warped versions (include scale variation, rotation, occlusion and illumination changes) for the previous tracking result. Also, we do not use the samples in models for sparse representation directly, but the Haar-like features instead which are compressed in a very low-dimensional space. In addition, we use a robust and fast algorithm which exploits the spatio-temporal context for predicting the target location in the next frame. This step will lead to the reduction of the searching range by the detector. We demonstrate the proposed method is able to track objects well under pose and scale variation, rotation, occlusion and illumination with great real-time performance on challenging image sequences.

Introduction

Visual Tracking has long been an importance topic in computer vision field due to its wide range of application for motion analysis, image compression and human-computer interaction. The main challenge for robust visual tracking is to deal numerous training samples included foreground and background cropped from consecutive frames due to occlusion, illumination changes and scale variation.

Recently, online classifier become popular in long-term object tracking. It has been demonstrated to be effective and efficiency for object tracking, but the models will be degraded with drifts caused by slight inaccuracy in tracking result. To deal with this challenging problem, Mei et al. [1] proposed an algorithm that considered the target as a sparse representation of target models and trivial templates. This algorithm is able to solve partial occlusion with trivial templates. However, the computational complexity is very significant. Dinh et al. [2] propose a complex co-trainning approach using generative and discriminative trackers that deals with partial occlusion. Wang D et al. [3] propose an algorithm named SPTracker, which introduces l_1 regularization into the PCA reconstruction. The main components of our work are shown by Figure 1.

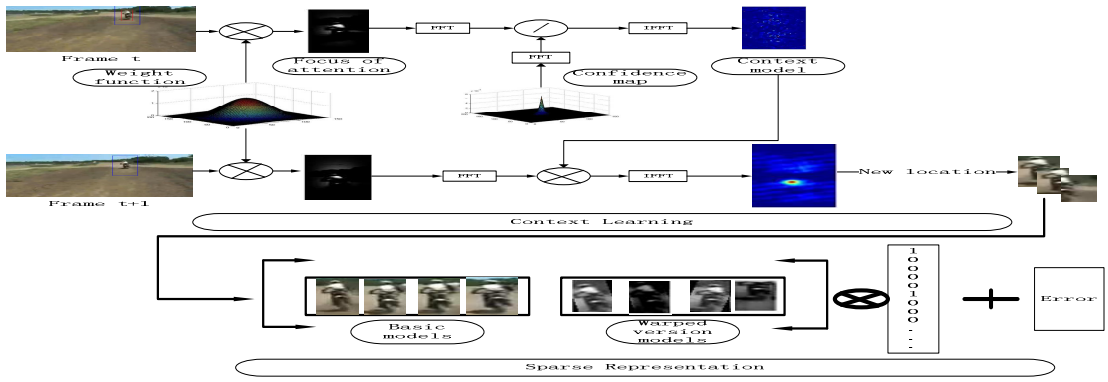

Fig.1 Main components of the proposed algorithm

Context learning

The context area in an image includes the target area (the region inside the red rectangle in fig.1) and its current surroundings [4](the region inside the blue rectangle in fig.1). From Fig.1 we know, the movement leads to the appearance of the target changing significantly, but the context area does not change much. Then, the current context area helps predict the object location in the next frame.

We define $o(x)$ as the target location likelihood, c denotes the object present in the scene. $x \in R^2$ is the object location. Then, the tracking problem is formulated as follows

$$o(x) = P(x \mid c) \tag{1}$$

Considering the context area in the current frame t, we define the context feature set as $F_S = \{f(x) = (I(y), y) \mid y \in S(x_t)\}$, where $I(y)$ denotes normalized image intensity at location y. $S(x_t)$ is the surrounding of the target location center x_t. Then, we denote the target location likelihood as the joint probability.

$$o(x) = P(x \mid c) = \sum_{f(x) \in F_S} P(x, f(y) \mid c) \tag{2}$$

From probability theory we know, the joint probability can be written as conditional probability $P(x \mid f(x), c)$ multiply the prior probability $p(f(x) \mid c)$.

$$o(x) = P(x \mid c) = \sum_{f(x) \in F_S} P(x \mid f(y), c) * P(f(y) \mid c) \tag{3}$$

The conditional probability function $P(x \mid f(y), c)$ is defined as

$$P(x \mid f(y), c) = h(x - y) \tag{4}$$

$P(x \mid f(y), c)$ encodes the spatial relationship between the target and its current context. $h(x-y)$ is a system transfer function with the distance between object location x and its current context y.

We model the context prior probability as follows:

$$P(f(y) \mid c) = I(y) * w_\partial(y - x_t) \tag{5}$$

Where $w_\partial(y - x_t)$ is a weighted function defined by

$$w_\partial(y - x_t) = \frac{1}{K} e^{-\frac{(y - x_t)^2}{\partial^2}} \tag{6}$$

Where k is a normalization constant to keep $P(f(y) \mid c)$ range from 0 to 1. ∂ is a scale parameter.

The target location confidence map is defined as

$$o(x) = \frac{1}{M} e^{-(\frac{x - x_t}{\beta})^\gamma} \tag{7}$$

Where M is a normalization constant, β is a scale parameter and γ is a shape parameter.Then, we formulate as

$$o(x)=\frac{1}{M}e^{-(\frac{x-x_t}{\beta})^{\gamma}}=\sum_{y\in S(x_t)}h(x-y)I(y)w_{\partial}(x-x_t)=h(x)\otimes(I(y)w_{\partial}(x-x_t)) \tag{8}$$

We calculate the equation (8) in the frequency domain using the FFT algorithm.

$$T(\frac{1}{M}e^{-(\frac{x-x_t}{\beta})^{\gamma}})=T(h(x))\times T(I(y)w_{\partial}(x-x_t)) \tag{9}$$

Therefore, we get

$$h(x)=T^{-1}(\frac{T(\frac{1}{M}e^{-(\frac{x-x_t}{\beta})^{\gamma}})}{T(I(y)w_{\partial}(x-x_t))}) \tag{10}$$

Then,

$$o_{t+1}(x)=T^{-1}\left(T(H_{t+1}(x))\times T(I_{t+1}(y)w_{\partial}(x-x_t))\right) \tag{11}$$

We get the target location in the next frame.

$$x_{t+1}=\arg\max_{x\in S(x_t)}o_{t+1}(x) \tag{12}$$

The context transfer function is update by

$$H_{t+1}=(1-\rho)H_t+\rho h_t \tag{13}$$

Where, ρ is a learning parameter and h_t is computed by equation (10).

The scale s is update by

$$\tau_t=\sqrt{\frac{o_t(x_t)}{o_{t-1}(x_{t-1})}},\bar{\tau}_t=\frac{1}{n}\sum_{i=1}^{n}\tau_{t-i},s_{t+1}=(1-\lambda)s_t+\lambda\bar{\tau}_t,\partial_{t+1}=s_t\partial_t \tag{14}$$

Where, τ_t is the estimated scale between two consecutive frames. s_t is average of the estimated scales from n consecutive frames. $\lambda\in(0,1)$.

Haar-like features extraction and compression

The key advantage of a Haar-like feature over most other features is its fewer computation complexity. Due to the use of integral images, a Haar-like feature of any size can be calculated in constant time. This allows to compute sum of rectangular areas in the image, at any position or scale, using only four lookups:

$$Sum(r)=I'(x_0+w,y_0+h)+I'(x_0,y_0)-I'(x_0+w,y_0)-I'(x_0,y_0+h) \tag{11}$$

Where, $I'(x,y)$ is the integral image and $Sum(r)$ is the sum of pixels in the rectangle $[x_0,y_0,w,h]$.

From Compressive Tracking Algorithm we know, there is a very sparse random measurement matrix whose rows have unit length projects data from high dimensional image space to a lower dimensional space.

$$v=Rx \tag{12}$$

Where, $x\in R^m$ is a high-dimensional image space, $v\in R^n$ is the corresponding lower-dimensional space, $n<<m$.

The random measurement matrix [5] is defined as

$$r_{i,j}=\sqrt{s}\begin{cases}1, & with\ \ probability\ \ \frac{1}{2s}\\ 0, & with\ \ probability\ \ 1-\frac{1}{s}\\ -1, & with\ \ probability\ \ \frac{1}{2s}\end{cases} \tag{13}$$

If $s=3$, R is very sparse where only one thirds of computation needs to do. If $s=m/4$, for each row of R, only about c, $c\le 4$, entries need to be computed. As a result, the computational

complexity is only $O(cn)$ which is very low. In addition, only nonzero entries of R need to memory. It is very useful for real-time.

Sparse representation

Sparse representation has been widely used in computer vision. Many methods cast the tracking problem as finding the most correct sample with the smallest projection error.

$$y = Az + e \tag{14}$$

Where $A \in R^{d \times n}$ is a matrix of templates, y represents an observation vector and e denotes the projection error.

In the paper, A includes two part,

$$A = [B, W] \tag{15}$$

Where, B represents the basic models and W represents the warped version models. The equation (14) can be written as

$$y = [B, W] * z + e \tag{16}$$

As it requires solving a series of l_1 minimization problems, it often deals with low-resolution images and the computational complexity is significant. We exploit the compressibility in the transform domain by solving the problem as an l_2-regularized least squares problem, which can be written as

$$z = \min \left\| y - [B, W] z \right\|_2^2 + \lambda \left\| z \right\|_2^2 \tag{17}$$

Where, $\left\| \bullet \right\|_2$ denotes the l_2 norms.

Rigamonti R [6] and Xiao Z-Y [7] solves this problem as

$$z = ([B, W]^T [B, W] + \lambda I)^{-1} [B, W]^T y \tag{18}$$

$I \in R^{d \times d}$ is the identity matrix, $\lambda = 1$.

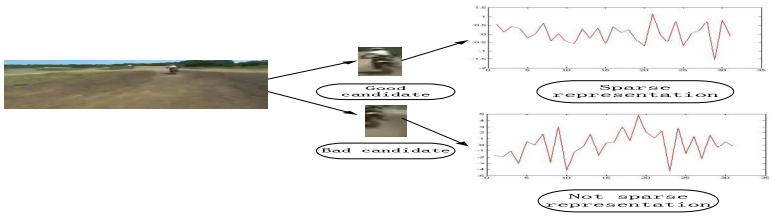

Fig.2 Good and bad candidates approximated by model A

Fig.2 shows the coefficients approximated by the model A for the good and bad target candidates. The coefficients of the good candidate are relative small comparing to the bad candidate coefficients and most of good candidate coefficients are near to 0, only a few are relative big. The bad candidate coefficients are on the contrary.

Then, e can be denoted as

$$e = y - [B, W] z \tag{19}$$

Finally, we can find the most correct sample y_{t+1} as the tracking result in frame t+1.

$$y_{t+1} = \arg\min_{y} (e^T e) \tag{20}$$

In this paper, A is the Haar-like features of basic models and warped version models. The basic models need not to be updated and the warped version models is updated every frame. We generate 20 warped versions by geometric transformations(for example shift $\pm 1\%$, scale change $\pm 1\%$, rotation $\pm 10^{\circ}$) for the previous tracking result and add them with Gaussian noise($\delta = 5$). In order to adapt to the illumination changes, we keep the gray value of the pixels change $\pm 20\%$.

(a) (b)

Fig.3 (a) Parts of the basic models. (b) Parts of the warped version models.

Experiment and conclusion

In order to evaluate our tracking algorithm, we use our method on 3 challenging sequences which are publicly available. Our algorithm is implemented in MATLAB which runs at about 40 frames per second on a Pentium Dual-Core 2.8GHz CPU with 4GB RAM.

Fig.4 Tracking result of the motorcycle by proposed algorithm

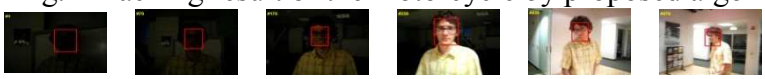

Fig.5 Tracking result of David in door with illumination changing by proposed algorithm

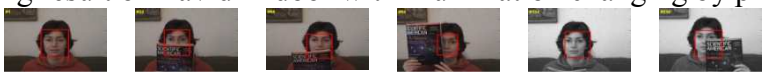

Fig.6 Tracking result of the heavy occlusions by proposed algorithm

From the result of the experiment we know, the proposed algorithm is able to adapt to size change, rotation, illumination change and heavy occlusions. Also, we use context learning to find the target location and scale in the next frame, so the number of testing samples becomes smaller. The context learning algorithm only uses 2 FFT and 2 IFFT operations. The computational complexity for each FFT is only $O(MN\log(MN))$ for the region of $M\times N$. The dimension of modes A always keep in low level and every column of A is compressed to a low-dimensional space (in our paper, $A\in R^{50\times 31}$). The computational complexity of the feature compression is only $O(cn)$ ($c\le 4, n==50$) as described above. If we extract testing samples from the whole image, there will be 50,000 testing samples in an image 320×240. But if we use context learning to find the target location in the next frame, we will only to deal with 900 testing samples in an image 320×240. So the proposed algorithm shows excellent real-time performance.

Keywords: Virtual Visual Servo, Virtual Model, RANSAC, Pose Estimation

Abstract. In this paper, on the basis of the robot visual servo system, a virtual visual servo algorithm for pose estimation is put forward. By reducing the image error between the current image features of real object and the features of virtual models, the rotation and translation relation of the virtual model is changed by visual servo control law, until the pose of virtual model overlaps the one of real object, and then object pose estimation is obtained. In addition, RANSAC algorithm is also introduced to improve the robustness of the proposed algorithm. Finally the experiment about camera external parameters estimation shows that our algorithm gets better results than the available parameter estimation algorithms.

Introduction

When the object model is known, pose estimation is a typical computer vision problem about PNP [1]. Many vision applications problems need pose estimation, such as 3D registration [2] in Augmented Reality, the camera external parameter calibration [3], and the manipulator grabs object [4] based on vision. The main problem currently existing in Augmented Reality System is registration, whose key point is to define the translation relationship between the actual object coordinate system and the virtual one's, namely to achieve pose estimation. The vision-based registration method is to use a CCD camera to obtain information of the real scene, build virtual objects, get control information by analyzing scene images generated by the camera, determine the relative position between the camera and the object, and put virtual objects in the real scene, then realize fusion display [5] of virtual objects and real scene. The camera external parameter calibration is to determine the model's pose relative to the camera coordinate system. The problem about grabbing objects based vision also needs accurate object pose in the camera coordinate frame.

Therefore, on the basis of the robot visual servo system, a virtual visual servo algorithm based on image for pose estimation is put forward. The idea is to convert the camera pose estimation problem into 2D visual servo problem, connect the points' movement in the image plane with the camera movement by Jacobian matrix, then rotate and translate the virtual model with virtual servo control law. When the image error is 0, the virtual model' pose is the real object's pose. This algorithm can solve pose estimation problems about the camera external parameter calibration, 3D registration and vision-based manipulator grabs objects.

Because the feature point extraction inaccuracy can lead to pose calculation error or mistakes, so how to eliminate points with bigger mensuration error and obtain the only pose in space is the most important part of our paper. We also combine with RANSAC algorithm[6], and calculate all possible poses in space after extraction of three feature points, which are continuously eliminate

"outer points", namely the pose calculated by inaccurate feature points, keep "interior points", thus expand the consistent set of candidate feature points, and make one pose in the consistent set as initial value, make the virtual model and real object overlapped with virtual visual servo algorithm, finally we can get the real object pose estimation in space.

Our Virtual Visual Servo System

Image-based robot visual servo system directly makes the image features as the feedback information, estimates the sensitivity matrix (image Jacobian matrix) between pose variation and image characteristics variation in real time, and then realizes the motion control of robot with Jacobi matrix. But the image-based visual servo algorithms for Jacobian matrix is particularly sensitive to the initial value, which usually needs a better initial a pose for controlled object to ensure that final estimation results.

However, in our paper, as Fig 1 shows, firstly assumed the world coordinate is concentric with the camera coordinate , the controlled object is a virtual checkerboard model, which exists in the virtual scene with 3D data at an arbitrary initial pose; secondly the algorithm makes the pose of the virtual model move constantly to pose 1,pose2…, reduces the error between the projection image and the real image; eventually when the image error is 0, the virtual model and real object get overlapped in three-dimensional space, namely realizes pose estimation of real object. The relationship between the virtual checkerboard model and the real model in the spatial coordinate frame is shown as Fig. 1：

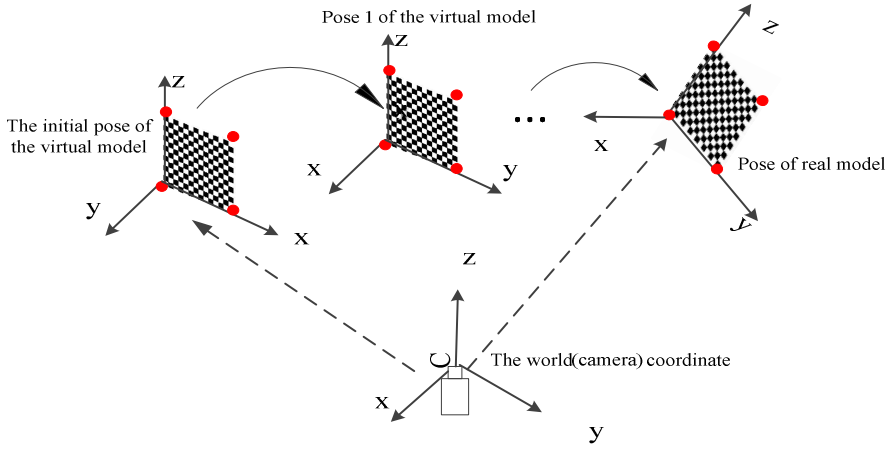

Fig.1.The relationship between the virtual model and the real object

In the process of our VVS system, we define the image feature set as S(·),Id is the real object image, then the real object image feature set is S(Id). Define virtual model as M, its initial pose is x_0 ,then $P(M,x_0)$ its virtual image in the pose of x_0, and its image feature set corresponding to the virtual model is $S(I)$, namely $S(P(M,x_0))$. The error function of the image feature can be defined as follows:

$$e=S(I)-S(I_d)=S(P(M,x_0))-S(I_d) \tag{1}$$

Define the camera internal parameters as K, then $P=K[R,T]$, R is rotation matrix, T is translation matrix. Let [R, T] row vector be $D=[R_x,R_y,R_z,T_x,T_y,T_z]$ namely the controlled variable. The structure of our virtual visual servo algorithm is shown in Fig. 2：

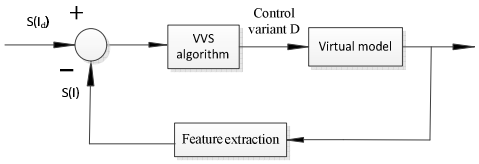

Fig.2.The structure of our virtual visual servo system

According to literature [7], J is defined as formula (2). (x_0,y_0,z_0), whose coordinates are expressed with respect to the space coordinate frame ;(x_c,y_c,z_c), whose coordinates are expressed with respect to the camera coordinate frame, will project onto the image plane with coordinates(x,y); f is focal length.

$$J=\begin{bmatrix} -\frac{f}{z_c} & 0 & \frac{x}{z_c} & \frac{xy}{f} & \frac{-f^2-x^2}{f} & y \\ 0 & -\frac{f}{z_c} & \frac{y}{z_c} & \frac{f^2+z^2}{f} & -\frac{xy}{f} & -x \end{bmatrix} \tag{2}$$

In the VVS algorithm, let $\dot{P}$ represent a vector of image feature parameters velocities, $\dot{r}$ is the virtual model pose velocity, i.e. differentials of controlled variable D. Their relationship is in formula (3):

$$\dot{P}=J\bullet\dot{r} \tag{3}$$

If we regard the virtual model as an output regulator, then $\dot{e}=-\lambda e$,so the absolute value of e decrease progressively in the way of index, λ is the proportional coefficient, then control rate can be calculated by the formula (1) and (3):

$$\dot{r}=-\lambda J^{+}e \tag{4}$$

J^{+} represents the pseudo-inverse matrix [8] of J in formula (4).

From the above, if the pseudo inverse Jacobi matrix is known, the virtual model pose velocity $\dot{r}$ can be calculated; the pose of virtual model will be changed constantly by controlled variable D in the space frame, until the image error is 0. Then the poses of the virtual model and the real object in three-dimensional space are totally overlapped, finally pose estimation of the real object can be attained.

Space pose estimation algorithm

RANSAC Algorithm.

RANSAC algorithm is a robust parameter estimation method. The basic idea is, first of all, according to the specific problem, to design an objective function, and through extracting the minimum point set repeatedly to estimate the initial parameters values in the function; then use the initial parameter values to divide all the data into the so-called "exterior points" (i.e. don't meet the estimated parameter) and "interior points" (i.e. meet the estimated parameter); finally, in turn, with all the "interior points" to calculate and estimate the function parameters. Fischler and Bolles give the RANSAC algorithm in literature [6], and points out that the P3P problem are up to four solutions, and the four the solutions can all be achieved. But we need a set of unique space pose, so in this paper, combined with RANSAC algorithm, we eliminate "outer points", make one pose in the "interior points" consistent set as initial value, greatly reduces the traditional visual servo dependence on the initial pose estimation, and it also has good accuracy and robustness.

Algorithm Flowchart.

Supposed the ideal number of interior points is N_d, set the threshold value for re-projection error as $\delta 1$, the threshold value for servo error as $\delta 2$, the sampling number is *N*.

1) Harris operator for corner points extraction;
2) Simply take three feature points in image space, using the analytical method to calculate all possible space poses;
3) According to the above space poses, figure the re-projection errors of all the feature points on the virtual model. If the re-projection error is less than the corresponding three feature points are "interior points", otherwise are "exterior points", record the number of interior points as *m*;
4) If m is less than N_d, then go to step 2);
5) According to all the above "interior points", calculate the space pose and make it as the initial value of VVS, then do the servo. If servo error is less than $\delta 2$, put the corresponding pose in the RANSAC consistent set, otherwise return to step 2);
6) Repeat step 2) to 5), until the sampling number is equal to *N*;
7) Finally let the mean value of poses in the consistent set as the initial value of VVS, and then run our VVS algorithm with all the interior points, and set the final pose of the virtual model as the best pose estimation result for the real object.

Experiment

The computer is AMD Athlon Ⅱ (tm) Processor with domain frequency of 3.0 GH in our experiment. We do the simulation with MATLAB

Fig. 3 is the checkerboard widely used among camera calibration algorithm [8].There are totally 156 small boxes, whose width and length are both 30millimeter. Establish the virtual chessboard model in accordance with the above parameters in the computer, and establish the local coordinate system as shown in figure 3.

Make one experiment as an example, extract three non-collinear points respectively (-45, 180, 0), (45, 90, 0), (-105, 90, 0) in the world coordinate frame; define the initial pose of the virtual model as [0 0 1 0; 0 1 0 0; -1 0 0 2]; after projecting, the three points' coordinates on the virtual model in image frame are (0.0413,3.0258),(0.0580,-1.3542),(-0.0125,-0.7359),compared to the real three points in the image frame are (0.2314,0.0131),(0.1402,0.0871),(-0.1050,-0.0511),the unit is millimeter.

Experiment Results.

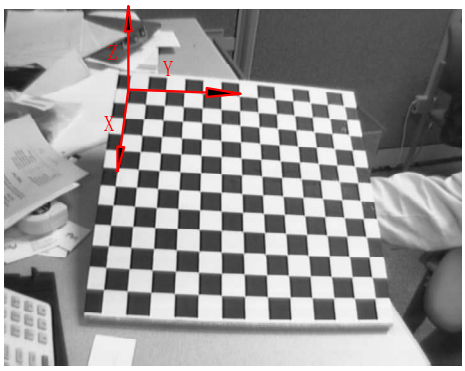

Fig.3. The checkerboard used in the experiment

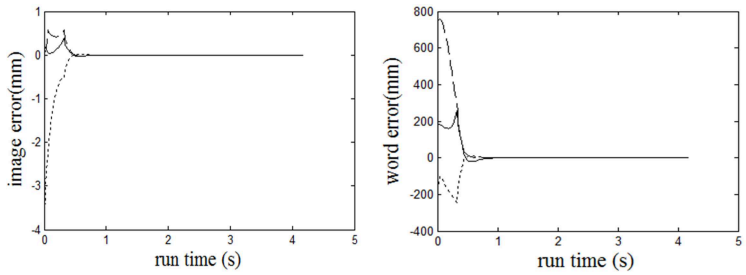
The image errors of three feature points are shown in Fig.4(a), the space errors in world coordinate frame are shown in Fig.4(b), then this pose of *R, T* which calculated by these points can be fit into a consistent set, otherwise should be abandoned, then we need to take three other feature points in the checkerboard again.



(a) (b)

Fig.4. (a)The image errors of the three points ;(b) the space errors of the three points

Fig.5 represents after VVS, we get the final pose of three feature points, namely external parameters, compared with the real pose. In this figure, we can see the camera coordinate system in 3D space. S1 is the initial pose of virtual checkerboard model, the light blue part represents the final virtual checkerboard after 211 times (about 1.5 seconds) our VVS iterative process; the pink part represents the real checkerboard pose in space. The virtual model and the real one are overlapped within the limits error; otherwise, we need to sample again, take three other feature points over again. In our experiment the sampling number is 60 times.

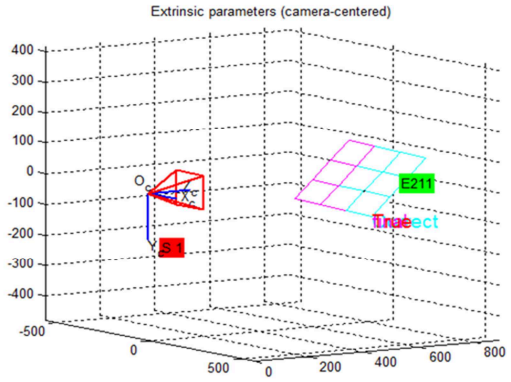


Fig.5. The pose comparison diagram of the virtual model and real object

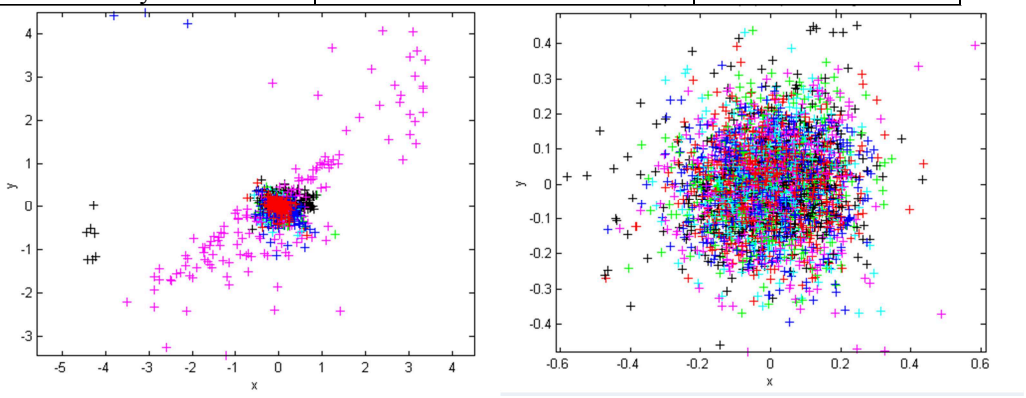
Fig.6(a) shows the re-projection errors distribution of feature points in the second checkerboard picture by MATLAB calibration method; Fig.6(b) shows the re-projection errors distribution by our method, with the unit for pixels. Table 1 is the standard deviation values comparison of re-projection errors by two methods. It is obvious that the image errors calculated by our method are much smaller than the MATLAB calibration method from Table 1 and Fig. 6.

Table1 The standard deviation values comparison of image error

standard deviation value	MATLAB calibration method	Our method
x	0.59063	0.11689
y	0.42185	0.11501



(a) (b)

Fig.6. (a) the re-projection errors with MATLAB calibration method; (b) the re-projection errors with our method

Discussion and Analysis.

In the experiment, we use the second picture from the typical checkerboard examples. The reason is that this picture is distorted, so it can't ensure the high extracting precision. If we simply take three feature points from the second picture, virtual model moves from any pose, the final pose estimation can have a larger deviation after running the MATLAB calibration algorithm. But the final pose estimation can still get good results in our way with the second picture.

Considering that the image has the aberrance and big yawp, corner extraction cannot guarantee all right, so we take 40 checkerboard images in different angles and conditions on the basis of the second one. The results show that within the error of a pixel, the accurate pose probability is 98.3% by our algorithm, while the accurate pose probability is 35.7% if using the VVS method only without removing "exterior points" based on RANSAC algorithm.

Conclusion

In this paper, we combine RANSAC algorithm and VVS algorithm, through the VVS algorithm to calculate the object's 3D pose estimation, then use RANSAC algorithm to pick up the best model parameters, and finally get the model pose estimation. The experiment results show the feasibility and robustness of this method. In addition, the proposed method can used in 3D AR registration and manipulator problem based on visual pose estimation, etc.

Keywords: CNN model; Path planning; Curvature constraint

Abstract. This paper proposes a new path planning algorithm based on the CNN model. The path planning problem is completed with the dynamics of CNN by establishing a relationship between path control points and CNN cells. Based on the analysis of one dimensional space of CNN algorithm, a CNN equation is constructed and the path updating algorithm under the curvature constraint is obtained, then the stability of the algorithm is discussed. Path planning simulation based on two-dimensional space shows that this algorithm can avoid re-planning or falling into the local minimum, which means it can be successfully used in the path planning and maintenance of robots on the ground in dynamic environment.

Introduction

Robot path planning [1] is an important part in robotics research, whose main task is to find a shortest path without collision with obstacles from the start state(including position and attitude) to the goal state(including position and attitude) based on certain evaluation criteria(for example, the least working cost or the shortest route). The research combining the underlying control and robot path planning algorithm is one of the development directions [2].

Cellular neural network (CNN) is one of the neural network models that proposed by Chua and Yang [3] in 1988. The network is a large-scale nonlinear simulation system which has such characteristics as the partially non-linear connection between cells, the piecewise linear output signal functions and continuous and real-time signal processing. CNN algorithm has been widely used to solve a variety of problems, including biological phenomena [4], image processing [5], mobile robot navigation [6], shortest path problem [7], and so on.

The algorithm proposed by this paper is different from the previous CNN algorithm. It avoids the problem, which may exist in the traditional gradient-based trajectory correction Snake maintenance algorithm [8] [9], that the trajectory converges to a local minimum and serious deviate from the desired results or even lead to fracture. The feasibility and stability of the equation solutions are discussed to ensure the path was simultaneously satisfying the conditions and avoid obstacle.

The CNN used for path planning

In a simplified one-dimension environment as show in Fig. 1(a), we horizontally place some sensor nodes which can communication with others and detect moving obstacles. The black blocks in the Fig. 1 are obstacles, white blocks are feasible regions. Assuming that the biggest width of these obstacles is 2W, the distance of feasible regions between obstacles is bigger than W. The purpose of path planning is finding the moving rules for control points (blue points in Fig. 1) and getting the motion trajectory which meets the curvature constraint $|x_{i+1}-2x_i+x_{i-1}|<C$ and avoids obstacles, where x_i is the one-dimension coordinate of control points, and C is the maximum curvature constraint of robot motion.

The initial state and control points in an already-planned optimal path trajectory are showed as the black curve in Fig. 1(a). When a sensor moves to the left (i.e. obstacles moves to the left), the trajectory will be continuously bending until it doesn't satisfy the curvature constraint or cracks (i.e. as the blue line shown in Fig. 1(b)) with the using of snake orbit maintenance algorithm. However, the cracking situation and obstacles can be avoided by using the dynamics of CNN, which can realize the jump between two steady states and it is manifested as the jump between the red and blue path trajectory in Fig. 1(b).

(a) Initiated optimal path trajectory (b) when obstacles move to the left

Fig.1. The path trajectory with obstacles

Define the distance between the control point x_i and the nearest obstacle o_i is

$$e_i = x_i - o_i \tag{1}$$

A one-dimensional CNN model is constituted by all the control points, where the control point x_i can be regarded as the i-th cell in 1 × N dimensional CNN model. Known from the CNN model, the state of the i-th cell is just affected by its surrounding cells' input and output. Simultaneously, the aim of constructing a CNN equation is to make the robot successfully avoid obstacles under the curvature constraint. Therefore, the input and output of the cell are constrained by both W and C.

According to the definition of saturation function $f(A,x)$, we can define the saturation function of W as $f(W,e_i)$, and the saturation function of C as $f(C, x_{i+1}-2x_i+x_{i-1})$.Then:

$$f(W, e_i) = \begin{cases} W & e_i > W \\ e_i & -W < e_i < W \\ -W & e_i < -W \end{cases} \tag{2}$$

$$f(C, x_{i+1}-2x_i + x_{i-1}) = \begin{cases} C & C > x_{i+1}-2x_i + x_{i-1} \\ -2e_i + M & -C < x_{i+1}-2x_i + x_{i-1} < C \\ -C & x_{i+1}-2x_i + x_{i-1} < -C \end{cases} \tag{3}$$

Substituting equation (1) in (3), the equation (3) can be changed as follows:

$$f(C, x_{i+1}-2x_i + x_{i-1}) = \begin{cases} C & e_i < \dfrac{M - C}{2} \\ -2e_i + M & \dfrac{M - C}{2} < e_i < \dfrac{M + C}{2} \\ -C & e_i > \dfrac{M + C}{2} \end{cases} \tag{4}$$

Where $M=x_{i+1}-2o_i+x_{i-1}$.

Combined with equation (2) (3), the CNN equation is constructed as follows:

$$\dot{e}_i = -e_i + a_i f(W, e_i) + b_i f(C, x_{i+1}-2x_i + x_{i-1}) + I \tag{5}$$

Where a_i and b_i are parameters, and $a_i>1$, $a_i = (a_{i-1})/C$..

In order to make the CNN equation (5) have stable solutions, we can make

$$I = -f(a_i - 1, \frac{b_i M}{2b_i + 1})$$

Refer to the standard CNN equation [10], the equation of CNN is shown as follows:

$$\dot{e}_i = -e_i + a_i f(W, e_i) + b_i f(C, -2e_i + M) - f(a_i - 1, \frac{b_i M}{2b_i + 1}) \quad (6)$$

The specific physical meaning of $a_i f(W,e_i)$ is to make x_i away from obstacles, and $b_i f(C, x_{i+1}-2x_i+x_{i-1})$ is constructed to make the curvature at point x_i meet curvature constraints after moving, and $-f(a_i-1, \frac{b_i M}{2b_i + 1})$ is the compensation of the equation to make sure that x_i doesn't move when there is no obstacle.

Stability analysis of CNN equation

Known from equation (2) and (3), there are four turning points $-$W, W, $\frac{M-C}{2}, \frac{M+C}{2}$ in the CNN equation's dynamic trajectory. As the size relationship of these four values changes with different values of variables, we discuss as follows.

(1) When $M>C+2W$, phase trajectories are shown in Fig. 2.

In this condition, $-W<W<\frac{M-C}{2}<\frac{M+C}{2}$, then we can infer that $a_i-1<\frac{b_i M}{2b_i+1}$ and $f(a_i-1, \frac{b_i M}{2b_i+1}) = a_i-1$.

Fig. 2 shows the dynamic trajectory and equilibrium points of cell circuit when $M>C+2W$. When $W\geq 1$, there are three equilibrium points Q_-,Q_0 and $Q_+$where $Q_-$and Q_+ are stable equilibrium points, and Q_0 is an unstable equilibrium points.

When $e \in (Q_0, Q_+), \dot{e} > 0$,it makes e approach Q_+along the dynamic track with the increasing trend. When $e \in (Q_+, \infty), \dot{e} < 0$, it makes e approach Q_+ along the dynamic track with the decreasing trend. Approximation trend is shown as the direction of the arrow, it obviously means that Q_+ meets the definition of a stable equilibrium point. Similarly, Q_- also is a stable equilibrium point. However, Q_0 belongs to be unstable as it doesn't meet the definition of a stable equilibrium point. According to the above analysis, there is one stable equilibrium point Q_+ when $W<1$. For all stable equilibrium points, $|e|\geq W$, which meet the stability requirements.

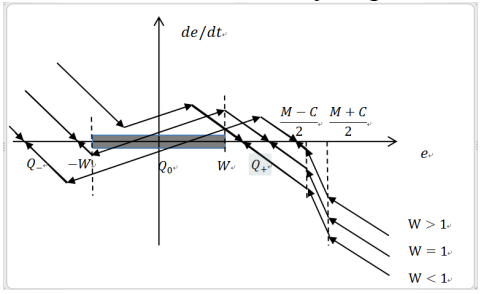

Fig. 2 Phase trajectories when $M>C+2W$

The stability of the equilibrium point analysis under other conditions is the same as Fig. 3, and $|e|\geq W$ holds on all stable equilibrium points which meet the stability requirements.

(2) When max(C-2W, 2W-C)<M<C+2W, C－2W<M<2W－C, C－2W>M>2W－C, －C－2W<M<min(C－2W,2W－C) , and M<－C－2W, the analyzing procedure refers to (1).

This section proves that CNN equation has stable solutions in theory and it can be used in path planning.

Experiments and results

In reality, robots' motion is on a two-dimensional plane. Taking that control point x_i in a two-dimensional plane and actual situation such as its movement trends into account, this paper transforms 2 degrees of freedom to 1 degree of freedom by rotating and counter-rotating, so that the CNN equation can maintain the path planning of robots on 2-dimensional ground.

We chooses one initial curve with arbitrarily settings as the optimal path obtained by traditional path planning algorithm to do the experiments of CNN path planning algorithm. 20 control points (shown as * in Fig. 3) are set by a certain distance in the curve, the first point and the end point are the start and end of the curve.

As the CNN equation just considers the impact of obstacles on its normal direction, it is assumed that, for each control point, it is affected only by obstacles parts on its normal line. Simulations have been finished at Matlab. With the same parameters (here we set a_i =1.5,C=5), the experiments results are shown in Fig. 3 and Table 1.In Fig 3, the black curve is the initial curve, the red curve is the curve after obstacle avoidance, black elongated strips are the sections of obstacles on normal direction of control points, with green points of center, blue points are stable equilibrium points calculated by CNN equation except for the selected one.

Table 1 The experiment's data

	x = 5	x = 6	x = 8	x = 10	x = 12	x = 16
The width of obstacles (W)	2	1.5	1	0.5	2	1
The distance between obstacles center and control points	1	-1.5	1.5	1.2	3	0
The final curvature	2.1020	2.1237	1.0107	0.7943	0.3461	1.1029

It can be seen from Fig. 3 that the point with maximum curvature is located at x = 6. Computing curvature at each point, there is the conclusion, $\forall i \in (1,20)$ and $C(x = i) \leq 5$, which effectively verify that the CNN algorithm can successfully avoid obstacles with satisfying the curvature constraints.

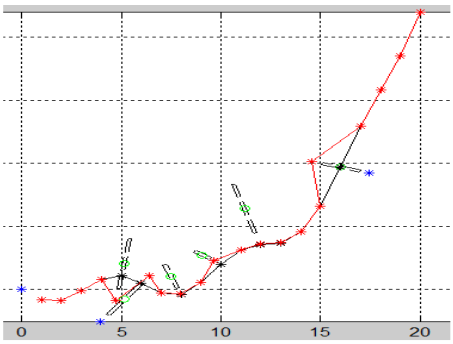

Fig. 3 The experiment result of CNN algorithm

Conclusion

By taking advantage of the CNN which has multi-stable points under different conditions, this paper realizes the timely avoidance of moving obstacles and ensures the achievement of path planning in dynamic environment. Then the existence and number of the stability solution of mentioned CNN equation are discussed to prove that CNN path planning algorithm can get a valid path. Finally, the experiment and simulation are finished to verify the correctness and effectiveness of the algorithm.

Compared with the previous CNN algorithm, the algorithm we mentioned is a more intuitive approach, which achieved a good planning result. As well, this paper only discusses the case with single robot, so it is necessary to make a further consideration on the path planning of multi-robot. Problem of obstacles' prediction is also required to be discussed.

Keywords: Brain Storm Optimization; Niche Technology; Multi-peak Function; Global Optimization

Abstract. Brain Storm Optimization (BSO) is a novel proposed swarm intelligence optimization algorithm which has a fast convergent speed. However, it is easy to trap into local optimal. In this paper, a new model based on niche technology, which is named Niche Brain Storm Optimization (NBSO), is proposed to overcome the shortcoming of BSO. Niche technology effectively prevents premature and maintains population diversity during the evolution process. NBSO shows excellent performance in searching global value and finding multiple global and local optimal solutions for the multi-peak problems. Several benchmark functions are introduced to evaluate its performance. Experimental results show that NBSO performs better than BSO in global searching ability and faster than Niche Genetic Algorithm (NGA) in finding peaks for multi-peak function.

Introduction

Swarm intelligence algorithms such as particle swarm algorithm [1], fish swarm algorithm [2], and artificial bee colony algorithm [3] have a rapid development in recent years because of their wide application in solving optimization problems. Brain Storm Optimization, inspired by emulating the swarm behaviors of human beings in the problem solving process, is a novel swarm intelligence algorithm which was first proposed by Shi in 2011 [4]. Shi and Zhan [5] demonstrated the feasibility and competence of BSO in function optimization problems. Now it is applied to many fields such as electromagnetic [6] and nonlinear equation solving [7].

The same as other optimization methods, BSO is easily trapped into local optima, besides it can not find multiple the global and local optima in multi-peak function optimization. To solve the problem, this paper proposed Niche Brain Storm Optimization, which modifies the structure of BSO based on niche technology [8] and maintains the diversity of population. Experiments show that NBSO has two advantages over BSO. First, it is easier to jump out the local optima and find the global optima. Second, it can find out all the optima of multi-peak function.

Brain Storm Optimization

Inspired by human creative problem solving process, BSO uses the grouping, replacing and creating operators to generate new individuals as many as possible to search the best individual generation by generation [9]. In the grouping operator, BSO uses a k-mean clustering method to group the N individuals into M clusters. A random cluster center will be replaced with a randomly generated individual in the replacing operator, creating operator means that BSO creates new individual by adding random noise to the current individual which is selected in one cluster or two clusters.

The probability of selecting each cluster j is as:

$$p_j = \frac{|M_j|}{N} \tag{1}$$

Where $|M_j|$ is the number of individuals in cluster j. It is obvious that the more individuals in the cluster, the larger chance it will be selected.

New individual is created as:

$$x_{newd} = x_{selected} + \xi * Norm(0,1)_d \quad (2)$$

$$\xi = \log sig((0.5 * T - t) / k) * random(0,1) \quad (3)$$

Where x_{newd} is the d dimension of the created new individual, $x_{selected}$ is the d dimension of the selected individual, T and t are the maximum number and generation number, k is for changing *logsig()* function's slope, $Norm(0,1)_d$ is the Gaussian random value with mean 0 and variance 1 and *random(0,1)* is a random value within(0,1).

The following is basic steps of BSO algorithm.

Step1: Initialization. Randomly generate N individuals and evaluate their fitness. Maximum number of iterations is T.

Step2: Cluster by k-mean.

Step3: With probability p_{5a}, replace a randomly selected cluster center with a randomly generated individual.

Step4: Randomly select a cluster j with a probability p_j.

Step5: With probability p_{6b}, select one cluster, otherwise, pick two clusters.

Step6: With probability p_{6biii}, select cluster center(s), otherwise randomly select other individuals.

Step7: Add random values to the selected individual to generate new individual

Step8: The newly generated individual is compared with the existing individual with the same individual index. The better one is kept and recorded as the new individual.

Step9: If N individuals have been updated, go to Step 10. Otherwise go back to Step4.

Step10: If the current number of iterations t is less than T, then go back to Step2, otherwise end the algorithm.

Niche Technology

In biology, a niche can be viewed as a subspace in the environment that can support different types of life. A species is defined as a group of individuals with similar biological features capable of interbreeding among themselves but that are unable to breed with individuals outside their group. Niching method is introduced in optimization algorithm to solve the complex multimodal function, because it maintains the diversity of population. Three types of niche are demonstrated in this section.

A. Crowding Niche

Crowding Niche inserts new elements in the population by replacing similar elements. In DeJong's crowding [10], only a fraction of the global population specified by a percentage G (generation gap) reproduces and dies each generation. In this crowding scheme, an offspring replaces the most similar individual (in terms of genotypic comparison) taken from a randomly drawn subpopulation of size CF (crowding factor) from the global population.

B. Fitness Sharing Niche

Fitness sharing modifies the search landscape by reducing the payoff in densely populated regions [11]. It lowers each population element's fitness by an amount nearly equal to the number of similar individuals in the population. Sharing must be implemented with the less biased selection methods and use low recombination operators to promote stability of subpopulations.

C. Clearing Niche

The clearing Niche is very similar to fitness sharing but is based on the concept of limited resources of the environment [12]. Instead of sharing the resources between all individuals of a single subpopulation as in fitness sharing, clearing attributes them only to the best members of the subpopulation.

Niche Brain Storm Optimization

BSO has a fast convergent speed at the beginning of search, however, the population diversity declines rapidly as the iteration goes on. In order to jump out of local optima, niche strategy is

introduced into the BSO. Niche is constructed by comparing Euclidean distance for every pair of individuals. If the distance is shorter than the preassigned distance L (niche radius), the individual with poor fitness is strictly punished by setting its fitness to low value. Thus, for two individuals within the preassigned distance L, the poor one will die out with high probability after several iterations. In this way, the best one is reserved within niche radius, so that individuals are distributed separately in the search space. NBSO maintains the diversity of population effectively, so it prevents premature convergence and can find all the global and local optimal of multi-peak function. There are three modifications in NBSO based on BSO.

1. Outside population with capacity K is introduced to preserve good individuals of revolution. Outside population preserves the fitness of K best individuals in the first iteration. In next iteration, outside population is refreshed by selecting K best individuals from $N+K$ population combining K outside population with N revolution population.

2. BSO selects a rand individual of cluster when new individuals are generated as step6 above. In NBSO, individual is selected according to its fitness in the cluster except for the center individual. Individual with high fitness will be selected with high probability. Because the fitness of poor individual in niche environment is set low value, it will be selected with low probability.

3. After new individuals are generated, the Euclidean distance between every pair of the new individuals is calculated and if the distance is shorter than L, the individual with high fitness is reserved while the poor one is set low value.

Experimental studies

In this section, NBSO is evaluated by using the multi-peak benchmark functions with a large number of local optima. Experiment I demonstrates the global searching ability of NBSO by comparing with BSO while Experiment II shows the peaks finding ability of NBSO in comparison with NGA.

A. Experiment I -- Global Searching Ability

Three benchmark functions listed in Table I are used in experiment I. Rosenbrock Function has a minimize value of zero with the location (1, 1). Schaffer Function has numerous local maximum, the global maximum is 1 with the location (0, 0). Shubert Function has 760 local minimum, the global minimum is -186.73 with the location (-1.4251,-0.8003).

BSO and NBSO are utilized to search the global optimal value. The global searching ability of an algorithm is evaluated by success rate. Success rate means the probability of an algorithm finding the global optimal value. Each algorithm is tested 50 times independently for every function and the mean results are used in comparison. Table II shows the success rate, mean fitness and optimal fitness found for benchmark functions.

According to table II, the success rate of NBSO approaches to 1 while BSO is 68% on average for all of the three functions. NBSO increases the success rate by 30% compared with BSO, which means NBSO has better ability of searching global optimal value than BSO.

Table I Test Function Used In the Comparison

Function	Test Function	Search Space
Rosenbrock	$f(x_1,x_2)=100(x_1^2-x_2)^2+(1-x_1)^2$	$-10\le x_1,x_2\le 10$
Schaffer	$f(x_1,x_2)=0.5-\frac{(\sin\sqrt{x_1^2+x_2^2})^2-0.5}{(1+0.001(x_1^2+x_2^2))^2}$	$-10\le x_1,x_2\le 10$
Shubert	$f(x_1,x_2)=\left\{\sum_{i=1}^{5} i\cos\left[(i+1)x_1+i\right]\right\}\left\{\sum_{i=1}^{5} i\cos\left[(i+1)x_2+i\right]\right\}$ $+0.5[(x_1+1.4251)^2+(x_2+0.8003)^2]$	$-10\le x_1,x_2\le 10$

Table II Success Rate, Mean Fitness and Optimal Fitness Found for Functions

Test Functions	BSO			NBSO		
	Success Rate (%)	Mean Fitness	Optimal Fitness	Success Rate (%)	Mean Fitness	Optimal Fitness
Rosenbrock	76	0.133	0	100	0	0
Schaffer	68	0.9952	1	98	0.9999	1
Shubert	62	-185.69	-186.73	98	-186.72	-186.73

B. Experiment II -- Global Searching Ability

To evaluate peaks finding ability of NBSO, three widely used benchmark multi-peak functions are introduced in the experiment.

$$F_1(x) = \sin^6(5.1\pi x + 0.5) \tag{4}$$

This function defined on $[0,1]$ consists of equally spaced peaks of uniform height. Maxima are located at the x values of 0.1, 0.3, 0.5, 0.7 and 0.9. All maxima are height of 1.0.

$$F_2(x) = x\sin^6(5.1\pi(x^2 - 0.57)) \tag{5}$$

F_2 is also defined on $[0,1]$ and consists of unequally spaced peaks of nouniform height. Maxima are of rounded height, 0.9297, 0.8176, 0.6872, 0.5258 and 0.2859.

$$F_3(x, y) = 200 - (x^2 + y - 11)^2 - (x + y^2 - 7)^2 \tag{6}$$

F_3 is defined on $-6 \le x,y \le 6$. It is a two dimension complex function and has 4 maximum with height of 200.

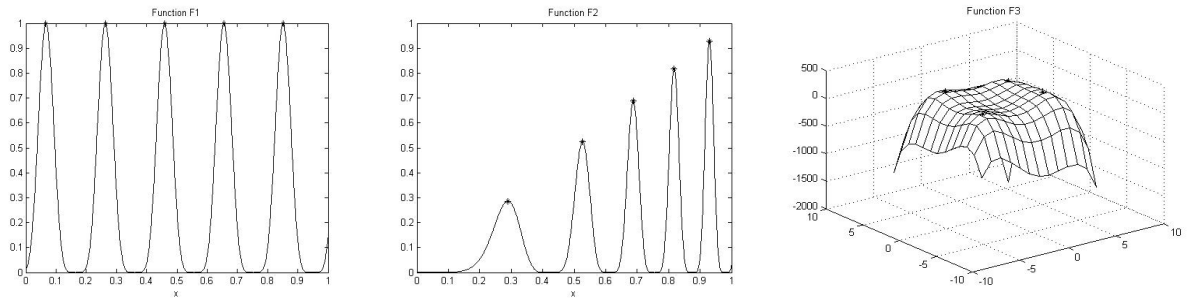
Effective Numbers of Peak: A peak is found if at least one individual of the population reaches the 99% height of the peak. The number of peaks found is called effective numbers of peak.

Maximum Peak Ratio (MPR): The maximum peak ratio is the effective numbers of peak divided by the number of all actual peaks in the search space [13]. It exhibits the ability of searching local maximum of an algorithm.

MPR of NBSO is calculated for three functions in different iterations and compared with that of NGA. Each algorithm is tested in 20 times. Table III shows the MPR of each function in different iterations, it is obvious that NBSO does better than NGA in finding peaks. NBSO can find more peaks than NGA at the same iteration, especially in complex multi-peak functions. Figure 1 shows the peaks found on different functions by NBSO.

Table III MAR For Test Functions in Different Iterations

Test Functions	Iteration / Algorithm	T=10	T=20	T=30	T=40	T=50
F_1	NGA	70%	86%	94%	100%	100%
	NBSO	92%	100%	100%	100%	100%
F_2	NGA	62%	76%	88%	96%	99%
	NBSO	90%	98%	100%	100%	100%
F_3	NGA	25%	52.5%	67.5%	85%	95%
	NBSO	72.5%	87.5%	96.25%	98.75%	100%



(a) F_1 (b) F_2 (c) F_3

Fig 1 Peaks found on different functions by NBSO

Conclusion

In this paper, niche technology is introduced into BSO algorithm to prevent premature. Niche technology can effectively maintain population diversity and enhance global searching ability of BSO. Experimental results show that NBSO has several advantages. First, NBSO has better ability to prevent premature when compared with BSO. Second, NBSO can effectively find multiple global and local optimal solutions for the multi-peak problems.

Keywords: Product Data Quality; Validation Rules; Rules Class

Abstract. Product data is the source data of product lifecycle in manufacturing enterprise. The quality of product data largely determines the effect of the application of Engineering analysis, simulation assembly and CNC programming work and so on. In order to solve the problems of the existing product data quality, such as validation custom trival, lack of high efficiency and flexibility, etc. The validation method of product data quality (PDQ) based on class was proposed in NX software environment, the representation of validation rules classes of product data quality, validation rules customization and implementation of validation process were introduced in detail in this study. Finally, an application case was employed to verify the practicability and effectiveness of the proposed method.

Introduction

Product data plays a key role in current product design and manufacturing processes including concept design, detail design, CAE, CAM and so on. However, because of the complexity of the product data itself, product data inevitably exist errors in the process of creating product data, so tend to hinder the product development process, and increase product development costs. The Japanese automotive industry spends about US$67 million a year to solve product data problems for approximately 250,000 cases .DaimlerChrysler estimates that as many as 10,000 of product data items should be repaired or adjusted due to the quality problem, an extra 5 million Euros is required in downstream processes [1]. Therefore, it is particularly important to carry out the related researches of product data quality assurance aspects. Son, et al. [2] developed a fully automated product 3D data quality validation and management system to support the product development processes of high-tech products like televisions, camcorders, mobile telephones, etc. Wang, et al. [3] proposed a rule-based data checking method of digital definition of mechanical products on the platform of NX software. Contero, et al. [4] presented a linguistics approach which emphasized the role of modeling techniques to achieve high-quality product data models. Kikuchi, et al. [5] reported the development of a PDQ standard (ISO 10303-59), which is a resource part of ISO 10303 Standard for the Exchange of Product Model Data. Kovacs, et al. [6] investigated the integration of PDM and workflow management systems and proposed a philosophy for the support of product data throughout the full development and production lifecycle. In this study, the validation method of product data quality based on class was proposed under NX software environment. In the following, a definition of product data quality is provided in section 2 and the representations of validation rules classes of product data is described in section 3. The validation process of product data quality is introduced in section 4. An application case in section 5 is given. A conclusion is included in section 6.

The Definition of Product Data Quality

- Product Data Quality (PDQ) is a measure of the accuracy and appropriateness of product data combined timeless with which those data are provided to all the people who need them (ISO TC184/SC4 N1944 2005). The term ‘product data’ is usually defined as any and all product data required from product conception to product manufacturing. Therefore, product data includes not just CAD data but also CAM data, CAE data, PDM data, and other kinds of data.

The Representation of Validation Rules Classes of Product Data

In order to check the quality of product data, it is very important to select a proper representation method for product data criteria. The representation of validation rules of product data can be better supported by Knowledge Fusion (KF), which is embedded object-oriented interpreted language of NX software.

The class definition of data validation rules based on KF language is as follows:

DefClass: <class name> (<parent class>);
(Data type Behavioral flag_1 Behavioral flag_2, ...)
Attribute Name: Parameter_1;
(Child) rule name:{class, …};
(Method Return Type) id:(type_1 $var_1, …)
@ {Statements…};
Defun: id(arglist) block Return Type;

The Validation Process of Product data Quality

The validation process of product data quality consists of four steps (Figure 1).

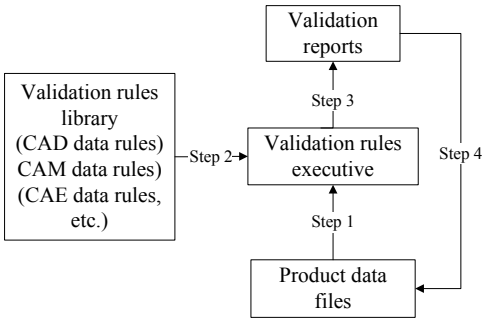

Fig. 1. The validation process of product data quality

Step 1: Create or open the validation data files.

Step 2: According to the requirements of product data quality, choose the corresponding validation rules from the validation rules library. Multiple validation rules can be chosen.

Step 3: Run validation rules, and generate the validation reports.

Step 4: To check the validation report, if there exist data errors, then modify product data files, until all the error modifications completed.

Application Case

The validation method of PDQ is evaluated using complex sheet body sewn by multiple trimmed sheet bodies (as shown in Figure 2).

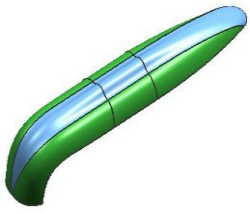

Fig. 2. The complex sheet body sewn by multiple trimmed sheet bodies

In the process of CAD modeling of automobile covering parts, the complex sheet body is often used, and usually be sewn by multiple trimmed sheet bodies. In order to ensure the CAD data quality of automobile covering parts, assuming that the product data quality of complex sheet body must meet the following criteria:

① The sewn tolerance of all sewn sheet bodies are not more than 0.02 mm.
② All sewn sheet bodies must be located in layer 10.

③ No other types of entities exist in the specified layer 10.

(1) The validation algorithm description of CAD data quality of complex sheet body

The validation algorithm of CAD data quality of complex sheet body was shown in Fig. 3.

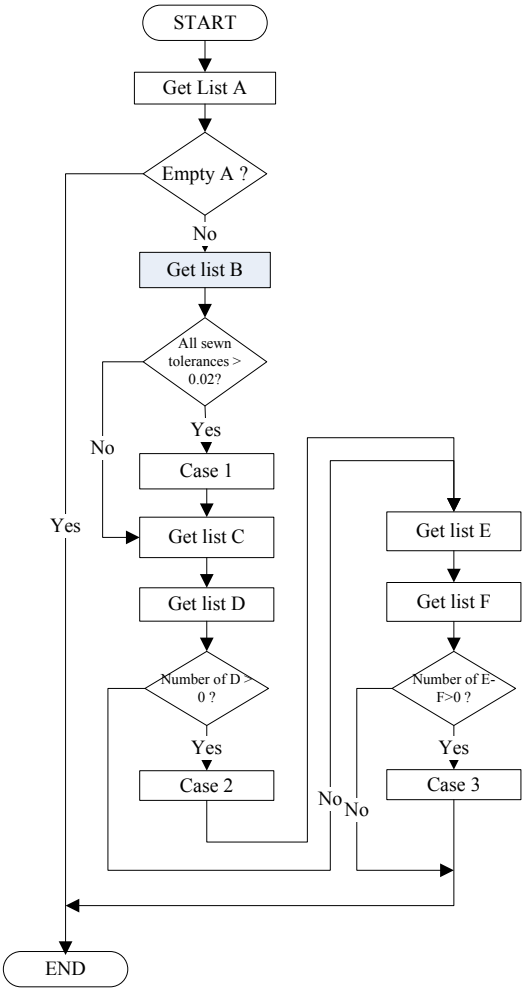

Fig. 3. The validation algorithm of CAD data quality of complex sheet body

In order to facilitate the algorithm description, the meanings of the following letters assumptions are as follows:

A: all trimmed sheet bodies;

B: all sewn sheet bodies (the child feature of trimmed sheet body);

C: all the sheet bodies in the specified layer;

D: all the sheet bodies that are not in the specified layer;

E: all the entities in the specified layer;

F: all the sewn sheet bodies in the specified layer;

E-F: other types of entities in the specified layer;

Case 1: Report errors, the sewn tolerances are more than 0.02 mm.

Case 2: Report errors, the sewn sheet bodies are not in specified layer.

Case 3: Report errors, the other type of entities exist in specified layer.

(2) The validation process of CAD data quality of complex sheet body

The validation process of CAD data quality of complex sheet body under NX software includes the following steps:

Step 1: Open CAD data file of complex sheet body (sew_sheets.prt) under NX software environment, and then enter the Check-mate function module.

Step 2: Determine the validation rules classes and customize related parameters.

Step 3: Run validation rules**.**

Step 4: Check validation reports (Figure 4). If find errors, modify the CAD data, until there are no errors.

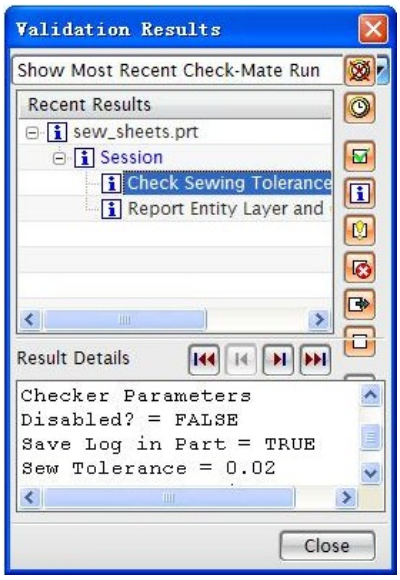

Fig. 4. Validation results

Conclusion

The validation method of product data quality based on class has been presented in this study. Especially, the method was implemented to support the product data validation in whole lifecycle. By applying the method, the designers can timely find the defects existing in the product data, so as to ensure the high quality of product data.

Stock price prediction model based on IWO neural network and its applications

Hong Liu[1,a] , Xiaoyan Lv[1,b]

[1]School of Science, University of Science and Technology Liaoning, Anshan 114051, China

[a]email: ldhliuhong@163.com,[b]email:lvxiaoyanlxy@yeah.net

Keywords: Invasive Weed Optimization; Feed-forward Neural Network; Stock Price Prediction

Abstract. In view of the deficiency of the standard back-propagation algorithm based on steepest descent method, a new kind of optimization strategy called invasive weed optimization(IWO) algorithm is introduced into the training process of feed-forward neural networks, and then a prediction model based on IWO feed-forward neural network(IWO-NN) is given. By the dynamic adjustment of standard deviation of the distribution of offspring individuals in IWO, the local convergence speed of networks is improved and the defect of trapping into a local optimum is reduced. By the empirical study of stock price prediction in Sany Heavy Industry, the results show that this method has better global astringency, robustness, and it is insensitive to initial values.

Introduction

The standard BP neural network algorithm is based on local search algorithm of gradient descent, which can not be used to search the global minimum points of multimodal function, it has high requirements to the functions and has the disadvantages of slow convergence speed, easy to trap into local minimum and low robustness and so on[1][2], therefore, some improved methods such as genetic algorithm, evolutionary algorithm and simulated annealing algorithm are used to train the feed-forward neural network.

IWO is a new intelligent stochastic search optimization algorithm, which is evolved from the evolution principle of weeds in nature. This algorithm mimics the basic process of spatial dispersal, growth, reproduction and competitive extinction of weeds invading into seeds and it has a strong adaptation and robustness [3]. In IWO, the group evolution is guided by the outstanding individual in the group, the offspring individuals are distributed around parent individuals with a normal distribution during the evolution process, and the standard deviation of normal distribution is adjusted and changed dynamically with the evolution generation, making the algorithm keeping the diversity of population in the early and middle evolution period, to overcome the phenomenon of premature convergence. In the later period, the local search ability of outstanding individual is stronger and stronger to ensure the algorithm approximate steadily the global optimal solution with higher accuracy. By comparing IWO algorithm with the simple particle swarm algorithm, IWO does not need too large storage space to save the track of particle; By comparing it with genetic algorithm, the structure of the algorithm structure is more simple and easy to realize, and it does not need the selection operator, crossover operator and mutation operator which are used in genetic operations, and can quickly and efficiently converge to the optimal solution of the problem. Therefore, we try to apply IWO algorithm to the training of feed-forward neural network to solve the problems of standard BP algorithm, and a prediction model is given, and then a practical simulation of stock price prediction is carried out, the feasibility and effectiveness are verified by comparing it with the standard BP algorithm.

IWO-NN prediction model

1.1 Prediction model of feed-forward neural network

The prediction refers to estimating values for future unknown data by some known historical data. Assuming that a time sequence$\{x_i\}$, among which the historical data is x_n ,x_{n+1} ,..., x_{n+m}, we want to predict the value at time $n+m+k$ ($k>0$), namely predicting nonlinear function relationship x_{n+m+k} at time $n+m+k$ ($k>0$), where the function relationship is $x_{n+m+k}=f(x_n,x_{n+1},\ldots,x_{n+m})$.

We use the feed-forward neural network to predict, that is we use neural network to fitting function f by a set of data points $x_n, x_{n+1}, \ldots, x_{n+m}$ and get the predicting value at future time $n+m+k$ ($k>0$).

The feed-forward neural network is a common artificial neural network model ,which has processing units of several connected layers, where each neuron in one layer is connected to every neuron in next layer, and there is no feedback in the network. In this paper, a three layer network is considered, which is widely used, the output layer is a linear layer, and the nonlinear effect function (the activation function) of neurons in hidden layer is a hyperbolic tangent function (*tan-sigmoid*):

$$\sigma(x)=\frac{1-e^{-x}}{1+e^{-x}} \tag{1}$$

Assuming the output of neurons in input layer is $P^i=(p_1,p_2,\ldots,p_R)$, $\{w1_{i,j}\}$ is the connection weights of input layer to hidden layer, $\{b1_{i,1}\}$ is the threshold value of neurons in hidden layer, $\{w2_{i,k}\}$ is the connection weights of hidden layer to output layer, and $\{b2_{i,1}\}$ is the threshold value of neurons in output layer. The mapping of input to output of network is:

$$y_k=\sum_{i=1}^{S_1} w2_{i,k}\sigma\left(\sum_{j=1}^{R} w1_{i,j}p_j+b1_{i,1}\right) \quad 1\le k\le S_2 \tag{2}$$

The training sample set of the feed-forward neural network is $A=\{(P^i, T^i), i=1,2,\ldots, s\}$, where s is the number of training samples, $P^i \in R^R$ is the input of training data in the i^{th} group, $T^i \in R^{S2}$ is the expectation output of corresponding input of training data in the i^{th} group, T_k^i is the expectation output of the k^{th} neuron in output layer. Assuming that the actual output of training data in i^{th} group is $Y^i \in R^{S2}$, Y_k^i is the actual output of the k^{th} neuron in output layer, then the error function based on the training sample set is given by:

$$E=\frac{1}{2}\sum_{i=1}^{s}\sum_{k=1}^{S_2}(Y_k^i-T_k^i)^2 \tag{3}$$

The function is a nonlinear function with various multiple minimum points, and the training process for this feed-forward neural network is adjusting the connection weights and threshold value of $\{w1_{i,j}\},\{b1_{i,1}\},\{w2_{i,k}\},\{b2_{i,1}\}$ until the error function E to minimum[4].

We can obtain the corresponding connection weights and thresholds $\{w1_{i,j}\},\{b1_{i,1}\},\{w2_{i,k}\},\{b2_{i,1}\}$ through being trained by the above feed-forward neural network. Then we can carry out specific problems of prediction by the prediction model of feed-forward neural network (2).

1.2 IWO Algorithm

The convergence is one of the most important characteristic of intelligent optimization algorithm, IWO algorithm relies on the guiding information of outstanding individual for the reproduction technique in development process, which is the foundation of convergence of algorithm. The dynamic adjustment of standard deviation in offspring distribution is the key point of the convergence of algorithm. The offspring individuals are distributed around parent individuals in normal distribution, making the algorithm achieve both selection and population diversity, to avoid the local maximum points availably and to ensure the stability of global convergence. The value range of the parameters is very wide, and the parameters do not highly depend on initial population. The steps of algorithm are listed below:

*step*1 Initialization of a population, we need determine the size P_{size} of initial population P(part of ethnic groups) and the size Q_{size} of ethnic groups Q, maximum iteration numbers $iter_{max}$, dimension of solving the problem *dim*, maximum generated seed number S_{max}, minimum generated seed number S_{min}, nonlinear modulation index n, initial value of interval step σ_{init} and final value of interval step σ_{final}, x_{min} and x_{max} respectively represent minimum value and maximum value of initial search space of independent variable.

*step*2 Randomly generate the initial solution by initial population, initial search space of independent variable and dimension of solving the problem.

*step*3 Refresh the iterations and the standard deviation of offspring normal distribution, which is calculated by

$$\sigma_{cur} = \frac{(iter_{\max} - iter)^n}{(iter_{\max})^n}\left(\sigma_{init} - \sigma_{final}\right) + \sigma_{final} \tag{4}$$

where *iter* is current number of iterations.

*step*4 Reproduction, the offspring are randomly distributed around parent by normal distribution $N(0,\sigma^2)$.The calculation of the offspring individual (seed number) depends on the fitness value of offspring. The number of offspring allowed by optimal fitness individual is S_{max}, and the number of offspring allowed by worst fitness individual is S_{min}, other number of offspring allowed obeys a round down linear relationship with their fitness. This mechanism is similar to the actual situation of weeds colony in nature, and the formula of generating seeds is

$$weed_n = \frac{f - f_{\min}}{f_{\max} - f_{\min}}(s_{\max} - s_{\min}) + s_{\min} \tag{5}$$

*step*5 Check whether the population number is the maximum. If the population number is not the maximum, return *step*4.

*step*6 If the number is greater than the maximum population number, compete and eliminate, the fittest is survival. Save the least fitness individuals, which is what we mentioned above, and the specific operation is rank the parent individual and offspring individual according the adaptive value, keep excellent fitness individuals to make the size of population within the maximum population. The operation that excellent individuals will be kept to the next generation ensures the convergence of the algorithm.

*step*7 Check whether the population number is the maximum. If not, repeat *step*4 to *step*6, otherwise, output the individual with the best fitness as the optimal solution.

1.3 Establishment of IWO-NN prediction model

1.3.1 Basic idea of training neural network based on IWO algorithm

Assuming that X is a feed-forward neural network $X=\{X_i|i=1,\ldots,p\}$, where X_i is the individual in population X, and p is the number of the individuals. Every individual X_i consists of two weight matrices $\{w1_{i,j}\},\{w2_{i,k}\}$ and two threshold matrices$\{b1_{i,1}\},\{b2_{i,1}\}$, the algorithm is to find the optimal X_i in $X=\{X_i|i=1,\ldots,p\}$and the optimizing function $minF(x)$ is the error function E (its expression is given in equation (3)). Then the error function E is optimized by IWO algorithm until satisfying the given stop conditions [4] [5].

1.3.2 Steps of training neural network based on IWO algorithm

*step*1 Randomly generate the initial solution, namely, population X, where each individual in the population is $X_i=[\ w1_{i,1}\ ,w1_{i,2},\ldots,w1_{i,n},\ b1_{i,1},\ w2_{i,1},w2_{i,2}\ ,\ldots,w2_{i,m}\ ,\ b2_{i,1}]$[6], $n=R\times S_1$, $m=S_1\times S_2$,R is the number of inputs neuron, S_1 is the number of neuron in hidden layer, and S_2 is the number of neuron in output layer. The initial individual number of the population is P_0, and the maximum number is Q. Calculate the fitness of each individual X_i.

*step*2 For the initial solution X, determine the allowed generated seed numbers by X_i in equation (5), where f is the fitness, thus the evaluation function $f= minF(x)$.

*step*3 According to equation (4), a new solution X_i is generated by adding a value D to the solution in each dimension, and calculate new individual fitness, where $D\in[-\sigma,\sigma]$;

*step*4 If the number of the existing solution is less than Q, go to *step*2; otherwise, go to *step*5;

*step*5 According to the competition rule of survival, choose Q numbers of the best fitness solutions;

*step*6 If $iter<iter_{max}$, jump to *step*2; otherwise, exit implementation process of the algorithm and output the optimal solution, and find the minimum fitness individual $X_i = [\ w1_{i,1}^*,\ w1_{i,2}^*,\ \ldots,\ w1_{i,n}^*,\ b1_{i,1}^*,\ w2_{i,1}^*,w2_{i,2}^*,\ldots,\ w2_{i,m}^*,\ b2_{i,1}^*]$ in the optimal solution.

1.3.3 IWO-NN prediction model

Firstly, collect the historical time sequence for network, to remove the dimensional level which has an impact on the training of neural network , and to increase the training speed ,we should normalize all the input variables and the original input data, which should be normalized to the range[-1,1]. The normalized training input is $P^i=(p_1,p_2,\ldots,p_R)^T$, the training target data is $T^i=(t_1,t_2,\ldots,t_{S2})^T$, the prediction input is $pX^i=(p_1^*,p_2^*,\ldots,p_R^*)^T$, and the actual target value is $pY^i= (t_1^*,t_2^*,\ldots,t_{S2}^*)^T$.

Secondly, input the normalized training input $P^i=(p_1,p_2,\ldots,p_R)^T$ and the training target data $T^i=(t_1,t_2,\ldots, t_{S2})^T$ to the network, and the optimal individual X^i is obtained by training as in part 1.3.2, the prediction model is obtained based on IWO algorithm by assigning the optimal individual X^i to weight matrices $\{w1_{i,j}^*\},\{w2_{i,k}^*\}$ and threshold matrices $\{b1_{i,1}^*\},\{b2_{i,1}^*\}$.

$$y_k=\sum_{i=1}^{S_1} w2_{i,k}^*\sigma(\sum_{j=1}^{R} w1_{i,j}^* p_j+b1_{i,1}^*) \qquad 1\le k\le S_2 \tag{6}$$

Finally, input the input variable $pX^i=(p_1^*,p_2^*,\ldots,p_R^*)^T$ to the prediction model, we need inverse normalize the prediction result $y_j=p_{j+1}$, and then the prediction true value is obtained.

Simulation analysis

2.1 Original data

In order to verify the effectiveness of IWO-NN prediction model, we specially select individual share of SANY Heavy Industry (stock code: 600031) as the stock price prediction object, whose stock prices do not appear too large oscillation. The basic data (including opening price, highest price, lowest price, closing price and volume) of 325 trading days are collected from 2005.6.30 to 2006.11.3 as historical samples, we want to predict the closing price of 2006.10.9 to 2006.11.3 according to the trained neural network, and compare the result with the actual closing price. Part of the historical stock prices of SANY Heavy Industry is shown in Tab.2.1 and Tab.2.2.

Tab2.1 300 samples of network training input/target data

Sequence	Opening price	Volume(shares)	Highest price	Lowest price	Closing price
1	7.74/7.16	3277048/2932205	7.95/7.29	7.60/7.11	7.69/7.16
2	7.60/7.13	7850876/4350030	7.61/7.22	7.00/6.8	7.00/6.85

2	13.96/16.50	1342635/3446818	14.26/17.08	13.75/16.2	14.18/17.02
⋮	⋮	⋮	⋮	⋮	⋮
20	18.00/18.30	2713835/1123350	19.19/18.88	18.0/18.15	19.12/18.47

2.2 Analysis of prediction results

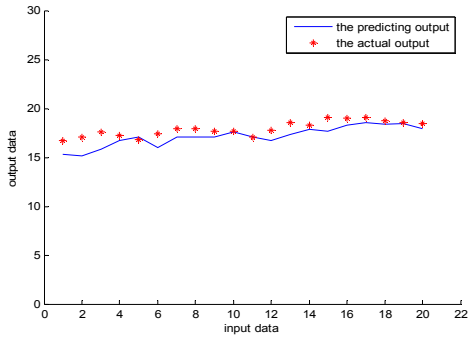
Firstly, before the training, in order to improve the training speed, reduce the error and avoid paralysis of network, the function mapminmax in neural network toolbox in Matlab is used to normalize the original sample data to obtain 300 sets of training inputs data P^i, 300 sets of training target data T^i, the last 20 sets of prediction inputs are pX^i, and actual target value are pY^i.

Secondly, the feed-forward neural network model is trained by IWO. In the feed-forward neural network, there are three layers, including input layer, one hidden layer and output layer, the corresponding nodes in each layer are R=25, S_1=16 and S_2=1, and *tan-sigmoid* function is used as excitation function. The initial population is P_{size}=3, the maximum of population is Q_{size} =16, the maximum iterations is $iter_{max}$=40, the maximum and minimum of generated seed number are S_{max}=3and S_{min}=0, the nonlinear modulation index is n=3, the initial value of interval step is σ_{init} =1and the final value of interval step is σ_{final}=0.01, the minimum of initial search space is x_{min}=-0.1 and the maximum is x_{max}=0.1. The training is carried out by inputting P^i and T^i to the network, and the optimal individual X_i=[$w1_{i,1}^*$,$w1_{i,2}^*$,…,$w1_{i,n}^*$, $b1_{i,1}^*$, $w2_{i,1}^*$,$w2_{i,2}^*$,…,$w2_{i,m}^*$, $b2_{i,1}^*$] is obtained. By assigning X_i to weight matrix $\{w1_{i,j}^*\},\{w2_{i,k}^*\}$ and threshold matrix $\{b1_{i,1}^*\},\{b2_{i,1}^*\}$ in the feed-forward neural network, the prediction model based on IWO algorithm is obtained,

$$y_k=\sum_{i=1}^{S_1} w2_{i,k}^*\sigma(\sum_{j=1}^{R} w1_{i,j}^* p_j+b1_{i,1}^*) \qquad 1\le k\le S_2 \tag{6}$$

where the connective weights of input layer to hidden layer $\{w1_{i,j}^{*}\}$ is $W1=\begin{pmatrix} -0.4684 & 1.1032 & \cdots & 0.1949 \\ -0.5262 & -0.3322 & \cdots & -0.2403 \\ \vdots & & & \vdots \\ 0.2148 & 0.0330 & \cdots & 0.3423 \end{pmatrix}_{16\times25}$, the connective weights of hidden layer to output layer $\{w2_{i,k}^{*}\}$ is $W2=(-0.0531 \quad -0.5523 \quad \cdots \quad 0.0282)_{1\times16}$, the threshold matrix $\{b1_{i,1}^{*}\}$ of neurons in hidden layer is $B_1=(0.3878 \quad -0.1588 \quad \cdots \quad 0.1250)^{T}_{16\times1}$, and the threshold matrix $\{b2_{i,1}^{*}\}$ of neurons in output layer is $B2=(-0.0673)_{1\times1}$.

Finally, input the last 20 prediction inputs pX^{i} to the prediction model (6), and then the final prediction true values are obtained by inverse normalization using postmnmx function in neural network toolbox in Matlab. The prediction of stock price is carried out by IWO-NN neural network, and the results are shown in Tab.2.3 and Fig.2.1, and the best fitness changes are shown in Fig.2.2.



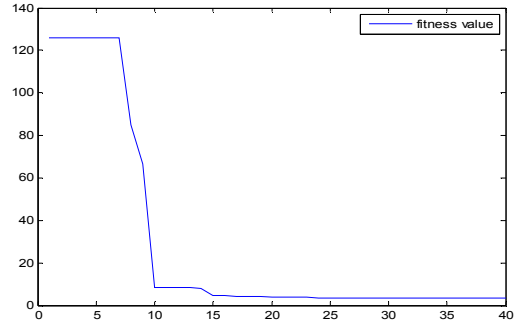


Fig2.1: Predicting the stock price based on IWO-NN Fig2.2: Change of best fitness based on IWO-NN

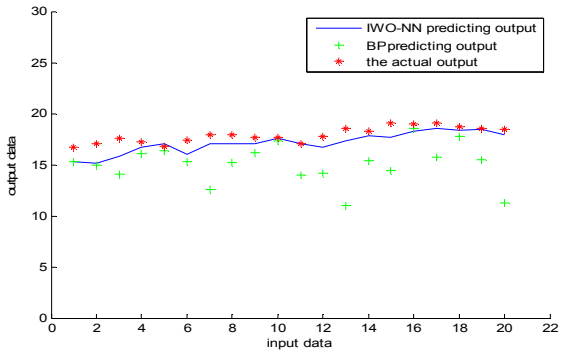

Fig2.3: Comparison on predicting stock price between BP neural network and IWO-NN

The comparison of prediction results between BP neural network and IWO-NN prediction model is shown in Fig.2.3.From the results, the prediction curve of prediction model trained by IWO is more approximate to actual value. The change curve of best fitness of IWO-NN model is shown in Fig.2.2, the optimal solution is obtained by the 25 iterations by IWO algorithm, which is increased significantly than the standard BP model. The comparison on the predicting closing price and actual closing price in different trading day and error of mean square between different predicting models is shown in Tab.2.3, it shows that the optimization of initial connection weights and threshold value of feed-forward neural network reflect a better tendency of network prediction changes, and the accuracy of the prediction is improved.

Tab2.3 Comparison on prediction results and errors about different predicting models

Trading day	Actual closing price	BP predicting price	IWO-NN predicting price	Trading day	Actual closing price	BP predicting price	IWO-NN predicting price
06.10.09	16.71	15.29	15.26	06.10.24	17.72	14.18	16.73
06.10.10	17.02	14.98	15.11	06.10.25	18.56	10.97	17.32
06.10.11	17.55	14.09	15.83	06.10.26	18.30	15.42	17.85
06.10.12	17.27	16.05	16.75	06.10.27	19.12	14.41	17.69
06.10.13	16.84	16.38	17.07	06.10.30	19.00	18.56	18.28
06.10.16	17.40	15.26	15.99	06.10.31	19.09	15.72	18.57
06.10.17	17.95	12.55	17.08	06.11.01	18.69	17.76	18.37
06.10.18	17.97	15.21	17.05	06.11.02	18.56	15.45	18.45
06.10.19	17.65	16.14	17.09	06.11.03	18.47	11.26	17.94
06.10.20	17.71	17.34	17.57				
06.10.23	17.06	13.94	17.09	Mean square error		12.3701	0.9378

From above analysis, IWO algorithm can find global initial connection weights and threshold value, improve the fitting ability and generalization ability of feed-forward neural network, thus improving the prediction accuracy of the network, therefore, it is an effective feed-forward prediction method.

Conclusion

Firstly, the training method of 3 layers feed-forward neural network based on IWO algorithm is given to make the network training simple and reduce the calculation complexity, the global search and local search are coordinate by the dynamic adjustment of standard deviation of offspring individuals' distribution, the optimal solution is obtained accurately, the defect of trapping into local optimization is reduced and the convergence speed is improved. Secondly, the IWO-NN prediction model is established. From the prediction results of stock price, the convergence speed and prediction accuracy are better than that of the standard BP neural network, and feasibility of the prediction method is verified. It also can be applied to the prediction in other areas by adjusting the training parameters, so it has a certain continuation.

Keywords: Fuzzy Clustering; Distance; Interval Slope; Interval Data

Abstract. Interval data is a range of continuous values which can describe the uncertainty. The traditional clustering methods ignore the structure information of intervals. And some modified ones have been developed. We have already used Taylor technique to perform well in the fuzzy c-means clustering algorithm. In this paper, we propose a new way based on the mixed interval slopes technique and interval computing. Experimental results also show the effectiveness of our approach.

Introduction

Real life problems are usually involved uncertainties. It is better to represent many kinds of phenomena by intervals than by single-valued variables. Especially, we do not know the variables' probability distribution and only know its ranges without more priori knowledge.

Interval data analysis was put forward by Moore [1] in 1965. As a widely used data mining technique, cluster analysis has been introduce in interval data and applied to diverse areas. Some people replace interval data with a single point (e.g. the middle point) to use the traditional clustering techniques [2] [3]. But these ways ignore the structure information of intervals and cannot measure the distance between two intervals well. Then many modified or extended methods for measuring the distance have also been developed [4-9]. About the problem of fuzzy c-means clustering interval data, we have obtained a good result by combining Taylor technique and interval computing [10].

Krawczyk and Neumaier firstly presented the interval slope for rational functions and associated centered forms [11]. Then [12] shows a combination of interval derivate arithmetic and interval slope arithmetic can often get a narrower interval enclosure than that which is gained by using them alone. In this paper, we apply this mixed arithmetic on the fuzzy c-means clustering algorithm. Compared with the proposed methods in [10], it has an equality fine clustering effect at least.

Interval Distance Measures

Interval data is a range of continuous values instead of the traditional single continuous or discrete value. It can be represented by a vector of interval values. Let $A = (A^1, A^2, \cdots, A^p)$ and $B = (B^1, B^2, \cdots, B^p)$ be two p-dimension interval objects, where $A^i = [a^i, b^i]$, $B^i = [c^i, d^i]$ indicate the interval values of the i-th variable and $a^i \le b^i$, $c^i \le d^i$. We denote the midpoint and the width of the interval A^i, B^i as $\tilde{A}^i, \tilde{B}^i$ and $\Delta_{A^i}, \Delta_{B^i}$ respectively, that is $A^i = [\tilde{A}^i - \Delta_{A^i}/2, \tilde{A}^i + \Delta_{A^i}/2]$ and $B^i = [\tilde{B}^i - \Delta_{B^i}/2, \tilde{B}^i + \Delta_{B^i}/2]$. And we have already known some distance measures in [10]. Here we will not describe these in details.

Just like the Taylor method, we hope obtain an interval data to express the distance. Taylor technique is a derivate arithmetic and interval slope approach is a differential arithmetic. Both of these can get an interval result, but their union would perform a narrower interval enclosure. The two algorithms are applicable to the so-called factorable function $f: D \subseteq R^n \longrightarrow R^1$ which can be represented by a finite simple expressions sequence such that:

$$f_i(x) = x_i \quad (i = 1, \ldots, n)$$

and for $i > j, k$,

$$f_i(x) = c_i \in R,$$

or

$$f_i(x) = -f_j(x),$$

or for $*\in \{+,-,\cdot,/\}$,

$$f_i(x) = f_j(x) * f_k(x),$$

$$f_i(x) = \emptyset_i(f_j(x)),$$

where

$$\emptyset_i \in \Phi = \{(\cdot)^{1/2}, \exp(\cdot), \ln(\cdot), \sin(\cdot), \dots\}.$$

The first order slope $f[x,z]$ and the second order slope $f[x,z,z]$ can be defined recursively in Tab.1 where $x,z \in D$ and $e^{(i)}$ is row i of $n \times n$ unit matrix.

Table 1.First and Second Order Slope

Expressions $f_i(x)$	**First order slope** $f_i[x,z]$	**Second order slope** $f_i[x,z,z]$
$f_i(x) = c_i \in R$	0	0
$f_i(x) = x_i$	$e^{(i)}$	0
$f_i(x) = -f_j(x)$	$-f_j[x,z]$	$-f_j[x,z,z]$
$f_i(x) = f_j(x) \pm f_k(x)$	$f_j[x,z] \pm f_k[x,z]$	$f_j[x,z,z] \pm f_k[x,z,z]$
$f_i(x) = f_j(x) \cdot f_k(x)$	$f_j[x,z]f_k(x) + f_j(z)f_k[x,z]$	$f_j[x,z,z]f_k(x) + f_k[x,z]^T f_j'(z) + f_j(z)f_k[x,z,z]$
$f_i(x) = f_j(x)/f_k(x)$	$\frac{f_j[x,z] - f_k[x,z]f_i(z)}{f_k(x)}$	$\frac{f_j[x,z,z] - f_i(z)f_k[x,z,z] - f_k[x,z]^T f_i'(z)}{f_k(x)}$
$f_i(x) = \emptyset_i(f_j(x))$	$\emptyset_i[f_j(x), f_j(z)]f_j[x,z]$	$\emptyset_i[f_j(x), f_j(z), f_j(z)]f_j[x,z]^T f_j[x,z] + \emptyset_i'(f_j(z))f_j[x,z,z]$

Table 2.First and Second Order Derivate

Expressions $f_i(x)$	**First order** $f_i'(x)$	**Second order** $f_i''(x)$
$f_i(x) = c_i \in R$	0	0
$f_i(x) = x_i$	$e^{(i)}$	0
$f_i(x) = -f_j(x)$	$-f_j'(x)$	$-f_i''(x)$
$f_i(x) = f_j(x) \pm f_k(x)$	$f_j'(x) \pm f_k'(x)$	$f_j''(x) \pm f_k''(x)$
$f_i(x) = f_j(x) \cdot f_k(x)$	$f_j'(x)f_k(x) + f_j(x)f_k'(x)$	$f_j''(x)f_k(x) + f_j'(x)^T f_k'(x) + f_k'(x)^T f_j'(x) + f_j(x)f_k''(x)$
$f_i(x) = f_j(x)/f_k(x)$	$\frac{f_j'(x) - f_k'(x)f_i(x)}{f_k(x)}$	$\frac{f_j''(x) - f_i'(x)^T f_k'(x) - f_k'(x)^T f_i'(x) - f_i(x)f_k''(x)}{f_k(x)}$
$f_i(x) = \emptyset_i(f_j(x))$	$\emptyset_i'(f_j(x))f_j'(x)$	$\emptyset_i''\left(f_j(x)\right)f_j'(x)^T f_j'(x) + \emptyset_i'(f_j(x))f_j''(x)$

Let real intervals be denoted by $X \in I(R^n)$ which is the set of interval vectors and let $\underline{\Phi}$ be the set of continuous isotonic interval extensions [12] of the functions in Φ. $\forall x,z \in X$, we can obtain

$$f(x) \in f(z) + f'(z)(X-z) + (X-z)^T f[X,z,z](X-z), \quad (1)$$

that is

$$f_S(X) = f(z) + f'(z)(X-z) + (X-z)^T f[X,z,z](X-z). \quad (2)$$

In comparison with Taylor method in which derivative arithmetic is displayed in Tab.2

$$f_T(X) = f(z) + f'(z)(X-z) + \frac{1}{2}(X-z)^T f''(X)(X-z), \quad (3)$$

it is clearly that $f_S(X) \subseteq f_T(X)$ and the computational complexity of the slope formulae is lower than that for derivative one. See [11] for a detailed analysis of the computational complexity.

We know the square root function of real number is a monotonic. It doesn't affect the final result of interval distance. So we can get the interval value of distance formula without squaring:

$$f(A,B) = \sum_{i=1}^{p}(A^i - B^i)^2. \quad (4)$$

To express conveniently and clearly, (4) can be replaced by

$$D^2(A,B) = [D^2(A,B)_{\min}, D^2(A,B)_{\max}] = f(X) = \sum_{i=1}^{p}\left(X^i - X^{i+p}\right)^2 \quad (5)$$

Where $X = (X^1, \cdots, X^p, X^{p+1}, \cdots, X^{2p}), A = (A^1, A^2, \cdots, A^p) = (X^1, X^2, \cdots, X^p), B = (B^1, B^2, \ldots, B^p) = (X^{p+1}, X^{P+2}, \cdots, X^{2p}), \tilde{A}^i = \tilde{X}^i, \tilde{B}^i = \tilde{X}^{p+i}$ and $\Delta_{A^i} = \Delta_{X^i}, \Delta_{B^i} = \Delta_{X^{p+i}}$. Referring to the previous way which has been used in k-means clustering, we get the distance square between *A* and *B*:

$$D^2(A,B) = \lambda D^2(A,B)_{\min} + (1-\lambda)D^2(A,B)_{\max}. \quad (6)$$

The parameter lies between 0 and 1 which is specified in such a way that $\lambda = 1$ indicates the minimum interval distance and $\lambda = 0$ indicates the maximum one. Then we separately apply the formulae in Tab.1 and Tab.2 to measure the interval distance. The basic operations like addition, subtraction, division and multiplication of interval data here are mentioned in [13].

Fuzzy c-means Clustering Interval Data

The objective in cluster analysis is to partition unlabeled objects into a number of clusters such that similar objects are assigned to one cluster. There are two main clustering approaches. One is crisp clustering; the other is fuzzy clustering which allows one piece of data to belong to more than one cluster and it is frequently used in pattern recognition [14] especially in cases that boundaries between clusters cannot be clearly defined. Fuzzy c-means (FCM) is a widely used method of clustering.

Consider a set of unlabeled interval patterns $A = (A_1, A_2, \cdots, A_n)$. Each $A_i = (A_i^1, \cdots, A_i^p)$ is a *p*-dimension interval object with $A_i^j = [a_i^j, b_i^j]$ and $a_i^j \le b_i^j$ where $i = 1, \ldots, n$ and $j = 1, \ldots, p$. Suppose we want to categorize the set into *K* clusters $C = (C_1, C_2, \cdots, C_K)$. Let their corresponding representations or clustering centers be $G = (G_1, C_2, \cdots, G_K)$ and $G_k = (g_k^1, \cdots, g_k^p)$ is a vector of interval values with $g_k^j = [c_k^j, d_k^j]$. The clustering is based on minimization of the following objective function:

$$J_m = \sum_{i=1}^{n}\sum_{j=1}^{K} u_{ij}^m d(A_i, G_j), \quad 1 \le m \le \infty. \quad (7)$$

In Equation (7), *m* is a real-valued number greater than 1(usually choose *m*=2) which controls the fuzziness of the resulting clusters, u_{ij} is the degree of membership of gene A_i in the cluster *j* and satisfies $\sum_{j=1}^{K} u_{ij} = 1$, $d(*)$ is a distance measure. Fuzzy partitioning is carried out through an iterative optimization of the objective function with the update of membership function matrix and the cluster centers by:

$$u_{ij} = 1/\sum_{c=1}^{K}\left(\frac{d(A_i,G_j)}{d(A_i,G_c)}\right)^{\frac{2}{m-1}}, \quad G_j = \frac{\sum_{i=1}^{n} u_{ij}^m \cdot A_i}{\sum_{i=1}^{n} u_{ij}^m}. \quad (8)$$

This iteration will not stop until $\max\{|u_{ij}^{k+1} - u_{ij}^k|\} < \varepsilon$, where ε is a termination condition and *k* is the iteration step. This procedure converges to a local minimum or a saddle point of J_m.

The algorithm can be composed of the following steps:

a) Initialize the membership matrix $U = [u_{ij}]$, $U^{(0)}$.

b) At *k*-step: calculate the centers vectors $G^{(k)} = [G_j]$ with $U^{(k)}$.

c) Update $U^{(k)}$ to obtain $U^{(k+1)}$.

d) If $\left\|U^{(k+1)} - U^{(k)}\right\| < \varepsilon$ then stop; otherwise return to step b).

By the way, each u_{ij} is a real number and each G_j is an interval vector. The distance measures used here have defined in the previous section.

Simulation experiment

In this section, we cluster the generated interval data in different distance measures which one of them is based on the mixed interval slope approach in the second part of this paper and others are

recommended in [10]. The software is written in Matlab 2011. It can be observed that the new one is better than previous methods and performs as well as at least.

We construct the same interval set as [10] with two-dimension interval vectors. We can plot these three different interval sets in Fig. 1.

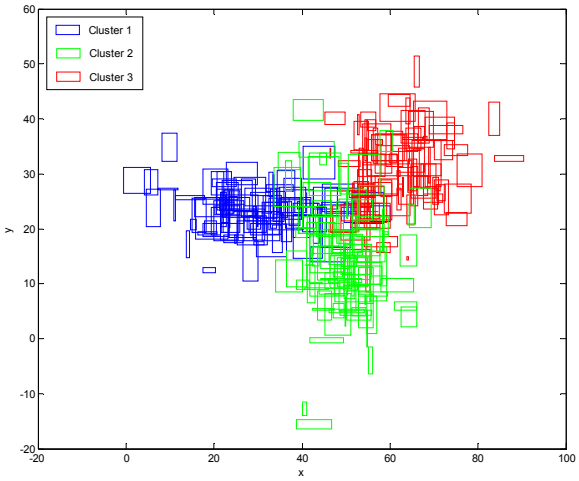

Figure 1.The plot of various interval sets

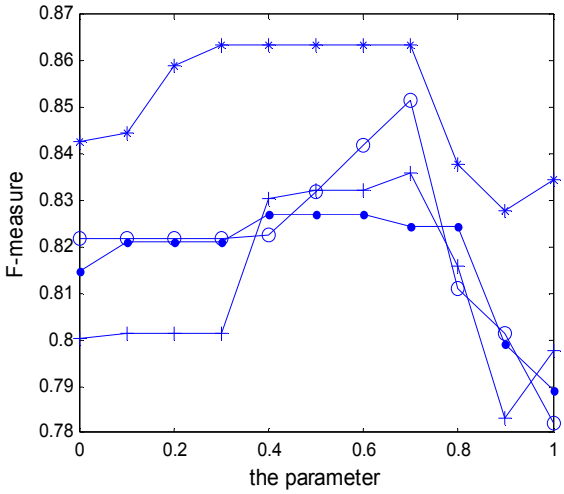

Figure 2.The relationship between the F-measure values and parameter λ

To evaluate the quality of clustering solutions we exploited the availability of reference classification for datasets. The objective is to evaluate how well a clustering fits a predefined scheme of known classes. To this end, we relied on the F-measure [14] which is one of the most commonly used external validity criteria and lies from 0 to 1. The larger F-measure value is better.

We can get relationships between the F-measure value and the parameter λ in mixed interval slopes method. When $\lambda = 0.8, 0.9$ or 1, there is a bad effect on the F-measure value. And it looks not good in small values. We can see some of the relation curves are stable and well-behaved if $\lambda = 0.4$ to 0.7 in Fig. 2. In the sixth one, we choose $\lambda = 0.7$.

For the comparative purpose, the criterion is an average value of 30 times. The results of F-measure values are listed in Table 3 in terms of various methods. The first five methods have presented in [10] and their parameters are no change.

Table 3.The F-measure values of different methods

Method	***F*-measure value**
Traditional Euclidean distance	0.7981
Extended Euclidean distance	0.8112
Relative position dissimilarity	0.8013
Yu Peng's distance measure	0.8647
Taylor technique	0.8705
mixed interval slopes technique	0.8705

Compared with the first three methods, it shows that the F-measure value of mixed interval slopes approach increases significantly. The last three methods have the highest similarity with the prototype and the algorithms can achieve a better clustering solution and validation.

Conclusion

In this paper, we study the problem of clustering interval data. We continue promoting the k-means method to fuzzy c-means algorithm and propose a new interval fuzzy clustering algorithm based on the interval slope approach. To compare with others by the F-measure value, the result of our experiment about two-dimension interval data performs that it can achieve a better clustering. And at least it has an equality fine clustering consequence as Taylor techniques. We discover the different values of the parameter λ will affect F-measure values. The influence in this method is

bad when the parameter is 0.8, 0.9 or 1 and is not good in small values, so the good choice of the parameter is 0.4 to 0.7. In the entire value range of λ, we also find the *F*-measure variation range of the interval slope arithmetic is smaller and better than that of the Taylor arithmetic.

email: ldhliuhong@163.com

Keywords: Bat Algorithm; Feed-forward Neural Network; Stock Price Prediction

Abstract. In view of the deficiency of the basic back-propagation(BP) algorithm based on steepest descent method. Bat algorithm(BA)in intelligent optimization is introduced into the training process of feed-forward neural networks, capturing the optimal solution of the objective function with a small population size and less number of iterations, and a prediction model based on BA feed-forward neural network(BA-NN) is given. By the empirical study of stock price prediction in Sany Heavy Industry, the results show that this method has advantages of frequency tuning and dynamic control of exploration and exploitation by automatic switching to intensive exploitation if necessary.

Introduction

BA proposed by scholar Yang [1] in University of Cambridge is a Swarm intelligence optimization algorithm which mimics the behavior of the search by ultrasonic of bats in nature. In BA, The solution of optimization problem can be as a bat in the search space, where each bat has its corresponding fitness value, and the bat group search in the solution space following the current optimal bat by adjusting the frequency, loudness, rate of pulse emission. It has been proved that BA is better than genetic algorithm (GA) and particle swarm optimization (PSO) algorithm in solving unconstrained optimization problems [1].Therefore, BA has been widely used in numerical optimization, engineering optimization, constrained optimization, PFSP scheduling problem [2-5].

As the standard BP neural network algorithm is based on local search algorithm of gradient descent, which can not be used to search the global minimum points of multimodal function, and it has high requirements to the functions and has the disadvantages of slow convergence speed, easy to trap into local minimum and low robustness and so on [6] [7].BA is a new Swarm intelligence optimization algorithm. We apply BA to the training of feed-forward neural network in order to get rid of local minimum, trying to solve the problems of standard BP algorithm. A prediction model based on BA feed-forward neural network (BA-NN) is given, and a practical simulation of stock price prediction is carried out, and the feasibility and effectiveness of it are verified by comparing it with the standard BP algorithm.

BA-NN prediction model

1.1 Prediction model of feed-forward neural network

The prediction refers to estimating values for future unknown data by some known historical data. Assuming that a time sequence$\{x_i\}$, among which the historical data is x_n ,x_{n+1} ,..., x_{n+m}, we want to predict the value at time $n+m+k$ ($k>0$), namely predicting nonlinear function relationship x_{n+m+k} at time $n+m+k$ ($k>0$), where the function relationship is $x_{n+m+k}=f(x_n,x_{n+1},\ldots,x_{n+m})$.

We use the feed-forward neural network to predict, that is we use neural network to fitting function f by a set of data points $x_n,x_{n+1},\ldots, x_{n+m}$ and get the predicting value at future time $n+m+k$ ($k>0$).

The feed-forward neural network is a common artificial neural network model ,which has processing units of several connected layers, where each neuron in one layer is connected to every neuron in next layer, and there is no feedback in the network. In this paper, a three layer network is

considered, which is widely used, the output layer is a linear layer, and the nonlinear effect function (the activation function) of neurons in hidden layer is a hyperbolic tangent function (*tan-sigmoid*):

$$\sigma(x)=\frac{1-e^{-x}}{1+e^{-x}} \tag{1}$$

Assuming the output of neurons in input layer is $P^i=(p_1,p_2,\ldots,p_R)$, $\{w1_{i,j}\}$ is the connection weights of input layer to hidden layer, $\{b1_{i,1}\}$ is the threshold value of neurons in hidden layer, $\{w2_{i,k}\}$ is the connection weights of hidden layer to output layer, and $\{b2_{i,1}\}$ is the threshold value of neurons in output layer. The mapping of input to output of network is:

$$y_k=\sum_{i=1}^{S_1} w2_{i,k}\sigma(\sum_{j=1}^{R} w1_{i,j}p_j+b1_{i,1}) \quad 1\le k\le S_2 \tag{2}$$

The training sample set of the feed-forward neural network is $A=\{(P^i,T^i), i=1,2,\ldots, s\}$, where s is the number of training samples, $P^i\in R^R$ is the input of training data in the i^{th} group, $T^i\in R^{S2}$ is the expectation output of corresponding input of training data in the i^{th} group, T_k^i is the expectation output of the k^{th} neuron in output layer. Assuming that the actual output of training data in i^{th} group is $Y^i\in R^{S2}$, Y_k^i is the actual output of the k^{th} neuron in output layer, then the error function based on the training sample set is given by:

$$E=\frac{1}{2}\sum_{i=1}^{s}\sum_{k=1}^{S_2}(Y_k^i-T_k^i)^2 \tag{3}$$

The function is a nonlinear function with various multiple minimum points, and the training process for this feed-forward neural network is adjusting the connection weights and threshold value of $\{w1_{i,j}\},\{b1_{i,1}\},\{w2_{i,k}\},\{b2_{i,1}\}$ until the error function E to minimum[4].

We can obtain the corresponding connection weights and thresholds $\{w1_{i,j}\},\{b1_{i,1}\},\{w2_{i,k}\},\{b2_{i,1}\}$ through being trained by the above feed-forward neural network. Then we can carry out specific problems of prediction by the prediction model of feed-forward neural network (2).

1.2 The principle of BA

Map the bat individuals to some points in the search space, measure the position of bat individual in the search space for fitness function value of solving problems(fitness function is the objective function of optimization problem).The search process of algorithm simulates searching for prey and moving process of bat individuals.

According to echolocation behavior of bats can being associated with the objective to be optimized. The following are respectively the mathematics form of population consisting of n bats updating their velocities, positions, loudness, and pulse rates during flight process.

1.2.1 The velocities update and positions update of bats

Assuming that the search space is D dimensional, the position of bat i at time t is x_i^t, the velocity is v_i^t. The new velocity $v_i^{t+1}$and position x_i^{t+1} at time step t+1 can be calculated by:

$$F_i=F_{\min}+(F_{\max}-F_{\min})\beta \tag{4}$$

$$v_i^{t+1}=v_i^t+(x_i^t-x_*) \tag{5}$$

$$x_i^{t+1}=x_i^t+v_i^{t+1} \tag{6}$$

where F_i, F_{max}, F_{min} respectively represent the frequency of the ultrasonic in the current moment, maximum and minimum of acoustic frequency of the bat i, $\beta\in[0,1]$ is a random vector, x_* represents the current global optimal solution.

For bat groups whose size is n, we can select one among them, and update corresponding position for the bat according to equation (7).This process can be understood as a local search process, namely, it selectively generate a new solution.

$$x_{new}(i)=x_{old}+\varepsilon A^t \tag{7}$$

Where x_{old} represents a solution randomly selected among the current best solutions set, A^t is the average loudness of the first i bats at time step t, $\varepsilon\in[-1,1]$ is a random number.

The update of the velocities and positions of bats have some similarity to the procedure in the standard PSO. To a degree, BA can be considered as a balanced combination of the standard PSO and the intensive local search controlled by the loudness and pulse rate.

1.2.2 Loudness and pulse emission

Normally, the loudness decreases gradually and the pulse rate increases gradually as a bat tends closer to its prey. Loudness of pulse $A(i)$ and rate of pulse emission $R(i)$ of bat i update according to the following formula (8):

$$A^{t+1}(i)=\alpha\cdot A^{t}(i)\ ,\quad R^{t+1}(i)=R_i^0\times[1-\exp(-\gamma\cdot t)] \tag{8}$$

where $0<\alpha<1$and$\gamma>0$are constants. Assuming $A(i)=0$ means a bat has just found the prey and temporarily stop emitting any sound. It is not hard to find that $A(i)\rightarrow 0$ and $R^t(i)= R^0(i)$ as $t\rightarrow\infty$.

1.3 Establishment of BA-NN prediction model

1.3.1 BA training neural network

Assuming that X is a feed-forward neural network $X=\{X_i|i=1,\ldots,p\}$, where X_i is the individual in population X, and p is the number of the individuals. Every individual X_i consists of two weight matrices $\{w1_{i,j}\},\{w2_{i,k}\}$ and two threshold matrices$\{b1_{i,1}\},\{b2_{i,1}\}$, the algorithm is to find the optimal X_i in $X=\{X_i|i=1,\ldots,p\}$and the optimizing function $minF(x)$ is the error function E (its expression is given in equation (3)). Then the error function E is optimized by BA until satisfying the given stop conditions. The steps of training neural network based on BA are below:

*step*1 Setting up the algorithm parameters, set t=0.

*step*2 Randomly generate the initial bat group's positions $X(0)=\{X_1(0), X_2(0),\ldots, X_{P0}(0)\}$,velocities $V(0)=\{V_1(0), V_2(0),\ldots, V_{P0}(0)\}$, while the individual's are $X_i(0)=\{X_1^i(0), X_2^i(0),\ldots, X_D^i(0)\}$and $V_i(0)=\{V_1^i(0), V_2^i(0),\ldots, V_D^i(0)\}$, where $D=R\times S_1 + S_1\times S_2 + S_1 + S_2$, $n=R\times S_1$, $m= S_1\times S_2$, R is the number of inputs neuron, $S_1$is the number of neuron in hidden layer, and S_2 is the number of neuron in output layer. The initial individual number of the population is P_0.

*step*3 Evaluate fitness value for every bat, and find out the location of the optimal bat.

*step*4 Judge whether the algorithm meets the condition (whether it reach the maximum number of iterations) .If meet, end the algorithm, output the optimal solution; or else, go to step5.

*step*5 Update velocity and position of bat according to formulas (4) to (6).

*step*6 Generate a random *rand*1, if *rand*1> r_i (r_i is pulse rates of bat i), disturb the current optimal bat position and obtain a new position, then replace the original position.

*step*7 Generate a random *rand*2, if *rand*2<A and $f(x_i)<f(x^*)$, then move to the updated location.

*Step*8 When it meets the conditions of step7, update pulse rates r_i and loudness A; otherwise, make $t=t+1$, return step3.

1.3.2 BA-NN prediction model

Firstly, collect the historical time sequence for network, to remove the dimensional level which has an impact on the training of neural network , and to increase the training speed ,we should normalize all the input variables and the original input data, which should be normalized to the range[-1,1]. The normalized training input is $P^i=(p_1,p_2,\ldots,p_R)^T$, the training target data is $T^i=(t_1,t_2,\ldots, t_{S2})^T$, the prediction input is $pX^i=(p_1^*,p_2^*,\ldots,p_R^*)^T$, and the actual target value is $pY^i= (t_1^*,t_2^*,\ldots, t_{S2}^*)^T$.

Secondly, input the normalized training input $P^i=(p_1,p_2,\ldots,p_R)^T$ and the training target data $T^i=(t_1,t_2,\ldots, t_{S2})^T$ to the network, and the optimal individual X^i is obtained by training as in part 1.3.2, the prediction model is obtained based on BA algorithm by assigning the optimal individual X^i to weight matrices$\{w1_{i,j}^*\},\{w2_{i,k}^*\}$and threshold matrices$\{b1_{i,1}^*\},\{b2_{i,1}^*\}$.

$$y_k=\sum_{i=1}^{S_1} w2_{i,k}^*\,\sigma\Big(\sum_{j=1}^{R} w1_{i,j}^*\,p_j+b1_{i,1}^*\Big)\qquad 1\le k\le S_2 \tag{9}$$

Finally, input the input variable $pX^i=(p_1^*,p_2^*,\ldots,p_R^*)^T$ to the prediction model, we need inverse normalize the prediction result $y_j=p_{j+1}$, and then the prediction true value is obtained.

Simulation analysis

2.1 Original data

In order to verify the effectiveness of BA-NN prediction model, we specially select individual share of SANY Heavy Industry (stock code: 600031) as the stock price prediction object, whose stock prices do not appear too large oscillation. The basic data (including opening price, highest price, lowest price, closing price and volume) of 325 trading days are collected from 2005.6.30 to

2006.11.3 as historical samples, we want to predict the closing price of 2006.10.9 to 2006.11.3 according to the trained neural network, and compare the result with the actual closing price. Part of the historical stock prices of SANY Heavy Industry is shown in Tab.2.1 and Tab.2.2.

Tab2.1 300 samples of network training input/target data

Sequence	Opening price	Volume(shares)	Highest price	Lowest price	Closing price
1	7.74/7.16	3277048/2932205	7.95/7.29	7.60/7.11	7.69/7.16
2	7.60/7.13	7850876/4350030	7.61/7.22	7.00/6.8	7.00/6.85
⋮	⋮	⋮	⋮	⋮	⋮
300	14.01/15.6	2595016/4516485	14.38/16.8	13.75/15.5	14.26/16.3

Tab 2.2 20 samples of network prediction input/actual value

Sequence	Opening price	Volume(shares)	Highest price	Lowest price	Closing price
1	14.21/16.35	2972750/3353063	14.30/17.36	13.6/16.01	13.98/16.71
2	13.96/16.50	1342635/3446818	14.26/17.08	13.75/16.2	14.18/17.02
⋮	⋮	⋮	⋮	⋮	⋮
20	18.00/18.30	2713835/1123350	19.19/18.88	18.0/18.15	19.12/18.47

2.2 Analysis of prediction results

Firstly, before the training, in order to improve the training speed, reduce the error and avoid paralysis of network, the function mapminmax in neural network toolbox in Matlab is used to normalize the original sample data to obtain 300 sets of training inputs data P^i, 300 sets of training target data T^i, the last 20 sets of prediction inputs are pX^i, and actual target value are pY^i.

Secondly, the feed-forward neural network model is trained by BA. In the feed-forward neural network, there are three layers, including input layer, one hidden layer and output layer, the corresponding nodes in each layer are R=25, S_1=16 and S_2=1,and *tan-sigmoid* function is used as excitation function. There is no exact theoretical basis about setting of various parameters involved in BA, so the values of the parameters set in this paper are the experience values based on repeated experiments. Set the range of search pulse frequency $F_i \in$[-0.1,0.1], maximum rate of pulse emission R^0=0.5, maximum loudness of pulse emission A^0=0.75, attenuation coefficient of loudness α=0.5, increase coefficient of pulse rate γ=0.05, maximum iterations *itmax*=300, the size of population n=40.

The training is carried out by inputting P^i and T^i to the network, and the optimal individual $X_i(t)=\{x_1^i(t), x_2^i(t),\ldots, x_D^i(t)\}$ is obtained. By assigning $X_i(t)$ to weight matrix $\{w1_{i,j}^*\},\{w2_{i,k}^*\}$ and threshold matrix $\{b1_{i,1}^*\},\{b2_{i,1}^*\}$ in the feed-forward neural network, the prediction model based on BA is obtained,

$$y_k=\sum_{i=1}^{S_1} w2_{i,k}^*\,\sigma\Big(\sum_{j=1}^{R} w1_{i,j}^*\,p_j+b1_{i,1}^*\Big) \qquad 1\le k\le S_2 \tag{9}$$

where the connective weights of input layer to hidden layer $\{w1_{i,j}^*\}$ is $W1=\begin{pmatrix} 0.1316 & -0.3009 & \cdots & 0.0117 \\ 0.0890 & 0.0690 & \cdots & -0.0048 \\ \vdots & & & \vdots \\ 0.1237 & -0.0312 & \cdots & 0.2344 \end{pmatrix}_{16\times 25}$, the connective weights of hidden layer to output layer $\{w2_{i,k}^*\}$ is $W2=(0.3185 \quad 0.1550 \quad \cdots \quad -0.1018)_{1\times 16}$, the threshold matrix $\{b1_{i,1}^*\}$ of neurons in hidden layer is $B1=(-0.0059 \quad 0.0226 \quad \cdots \quad -0.0628)_{16\times 1}^T$, and the threshold matrix $\{b2_{i,1}^*\}$ of neurons in output layer is $B2=(0.1979)_{1\times 1}$.

Finally, input the last 20 prediction inputs pX^i to the prediction model (9), and then the final prediction true values are obtained by inverse normalization using postmnmx function in neural network toolbox in Matlab.

The prediction of stock price is carried out by BA-NN neural network, and the results are shown in Tab.2.3 and Fig.2.1, and the best fitness changes are shown in Fig.2.2.

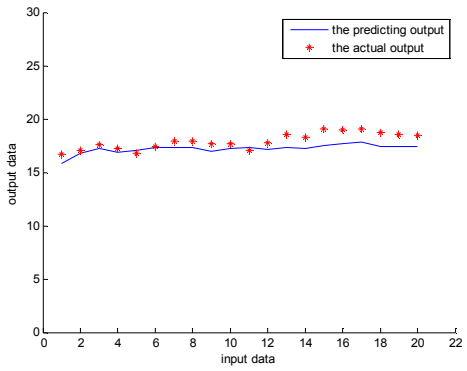

Fig.2.1: Predict the stock price based on BA-NN

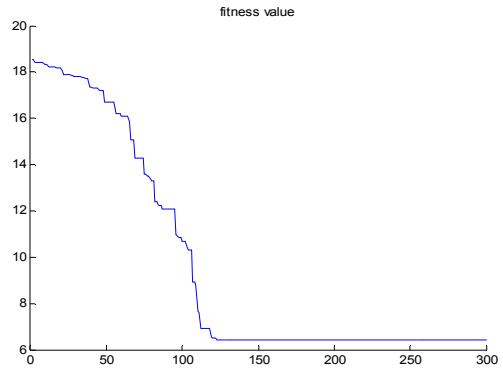

Fig.2.2: The change of best fitness based on BA-NN

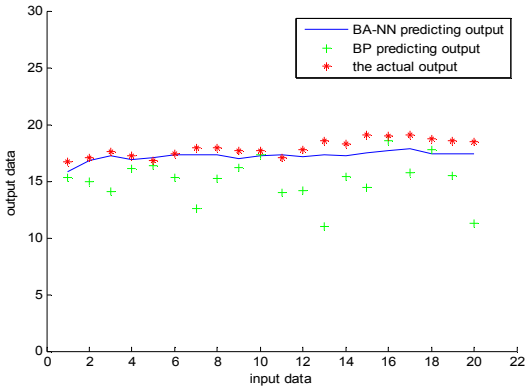

Fig2.3: Contrast on the predicting stock price between BP neural network and BA-NN

Tab.2.3 Comparison on the predicting results and errors about different predicting models

Trading day	Actual closing price	BP predicting price	BA-NN predicting price	Trading day	Actual closing price	BP predicting price	BA-NN predicting price
06.10.09	16.71	15.29	15.81	06.10.24	17.72	14.18	17.11
06.10.10	17.02	14.98	16.80	06.10.25	18.56	10.97	17.32
06.10.11	17.55	14.09	17.26	06.10.26	18.30	15.42	17.26
06.10.12	17.27	16.05	16.85	06.10.27	19.12	14.41	17.50
06.10.13	16.84	16.38	17.07	06.10.30	19.00	18.56	17.66
06.10.16	17.40	15.26	17.30	06.10.31	19.09	15.72	17.84
06.10.17	17.95	12.55	17.31	06.11.01	18.69	17.76	17.45
06.10.18	17.97	15.21	17.37	06.11.02	18.56	15.45	17.45
06.10.19	17.65	16.14	16.97	06.11.03	18.47	11.26	17.39
06.10.20	17.71	17.34	17.27				
06.10.23	17.06	13.94	17.32	Mean square error		12.3701	0.77989

The comparison of prediction results between BP neural network and BA-NN prediction model is shown in Fig.2.3.From the results, the prediction curve of prediction model trained by BA is more approximate to actual value. The change curve of best fitness of BA-NN model is shown in Fig.2.2, the optimal solution is obtained by the 150 iterations by BA, which is increased significantly than the standard BP model. The comparison on the predicting closing price and actual closing price in different trading day and error of mean square between different predicting models is shown in Tab.2.3, it shows that the optimization of initial connection weights and threshold value of feed-forward neural network reflect a better tendency of network prediction changes, and the accuracy of the prediction is improved.

From above analysis, BA can find global initial connection weights and threshold value, improve the fitting ability and generalization ability of feed-forward neural network, thus improving the prediction accuracy of the network, therefore, it is an effective feed-forward prediction method.

Conclusion

BA is a random search optimization algorithm based on population. The algorithm absorbs the behavioral characteristics of searching and preying by ultrasonic of bats in nature, implement the behavior of the agent by evolution to achieve the goal of optimization. The BA-NN prediction model based on BA is established. By example validation, the convergence speed and prediction accuracy have a higher increase than that of the standard BP neural network, achieving the purpose of our expectations, and it offers new ideas for forecasting stock price. Further by adjusting the parameters, this method can be used to solve the prediction problems in other areas.

Keywords: License Plate Location; Edge Detection; Morphology; Median-Filter

Abstract. A vehicle plate location algorithm under complex scenes is presented that based on interest region extraction and morphology. First of all, extract the edge of the lane, obtain the driveway area from the edge of the road, confirm the region of interest with the experiences in the driveway area, it can reduce the scope for searching. Then preprocessing is used in the vehicle image, including gray, edge detection and binary transformation is used. Then a series of morphological operations are used to look for candidate regions that probably contain the characters in range of sizes. Finally, the vehicle license plate can be found according to the median filter.

Introduction

Vehicle license plate recognition system is based on a specific target object dedicated computer vision system to automatically extract the image from a plate image, automatic segmentation of characters and character recognition. Vehicle license plate location is the key part of the vehicle license plate recognition technology. The main intention of the vehicle license plate location is located in the license plate from the input image and extracted license plate from the image. Under normal circumstances, automatic vehicle identification relies mainly on two key technologies, namely vehicle license plate location and character recognition. As a core technology, the accuracy rate and timeliness of the vehicle license plate location largely affect the merits of the license plate recognition system.

Researchers from different countries proposed a number of methods for extracting car license. Such as Texture-based segmentation method [1], based on the gray level variation of the method [2], based on neural networks [3]. These methods exists computationally intensive and inaccurate positioning problems. In more complex environmental positioning plates are obvious limitations. Therefore, the study removals interferences from the vehicle image in a complex background and effectively and quickly obtains the target plate is of great significance.

Interest Area Extraction

Vehicle detection algorithm is used here. First, extract the vehicle-related area as interested areas. Extraction of this region is divided into two parts: (a) Distinguish between road and non-road area. Road area is the interest area. (b) Texture features based on the edge of the vehicle to complete the background and foreground images of vehicle separation.

Driving region extraction

In the lane road image, lane usually has a clear edge. Therefore, the original image edge extraction as the pre-processing step is most commonly used [4]. Currently, there are a variety of edge extraction algorithms, such as Sobel, Laplace, Roberts, Prewitt, Canny and so on. By comparing these experimental methods for the purposes of this paper, the effect of Sobel algorithm is better. Other methods exist pumping side is not ideal, because it will affect the subsequent processing and some methods spend more time, unable to meet the requirements of real-time

systems. Therefore, this system used Sobel algorithm edge the extraction. Use horizontal Sobel operator $Sobel_x$ to obtain horizontal gradient map $G_x(x, y)$ and use vertical Sobel operator $Sobel_y$ to obtain vertical gradient map $G_y(x, y)$.

$$G_x(x,y) = Sobel_x(x,y) * I(x,y) \quad (1)$$

$$G_y(x,y) = Sobel_y(x,y) * I(x,y) \quad (2)$$

In the type $I(x, y)$ is the image to be processed. After the edge extraction pretreatment, the image is divided by using the Otsu multi-threshold segmentation algorithm [5]. The specific method is expressed as follows:

1) The initial state: d = 0 for the classification of the image already exists, end of the loop condition is S = 0, υ_T represents the total variance of the image.
2) If S does not satisfy the condition directly to the next step 3, otherwise go to 6.
3) For d different classes already exist in the image, seeking class variance within each class then found that the largest one.
4) Use the local Otsu method makes this class into two new classes, increase new segmentation threshold to the threshold that has been existed.
5) Recalculate υ_T, make a new assignment for S then go to 2.
6) Use the set of optimal threshold result from the above steps for image processing, segmenting out the road and non-road area.

Edge feature extraction based on vehicle

Edge confidence was used according to most of the edge contour of the vehicle is horizontal and vertical rectangular. Exclude a region not include the vehicle so that the vehicle may contain the region is retained. Horizontal and vertical edge detection based on Sobel operator to the Road regional image, to obtain the horizontal edge image I_H and vertical edge image I_V .Then sum the pixel values for each row to obtain a horizontal edge vector H and vertical edge vector V, search for the maximum to obtain confidence.

$$C_H = \frac{H_{max}}{n} \quad (3)$$

$$C_V = \frac{V_{max}}{n} \quad (4)$$

In the type, C_H stands for level confidence; C_V stands for vertical confidence. And if C_H and C_V are less than a certain threshold, it indicates that this region does not contain the vehicle, and shall be identified as background, as the results shown in Figure 1. We can remove the region of low edge confidence and reduce the amount of calculation of the algorithm.

Fig.1. The experimental results

Preprocessing the image region of interest

Processing vehicle image, the results shown in Figure 2.

(a) Gray processing (b) Binary processing (c) Marginalization

Fig.2. Processing vehicle image results

In this paper, the color of the vehicle image region of interest was extracted, converted to grayscale images, shown in Figure 2(a). Grayscale image processing standard formula for the average is:

$$Gray = 0.229*R + 0.587*G + 0.114*B \quad (5)$$

The edge in the image signal is expressed as gray mutation. Since only need processing the region of interest, so we use the Roberts operator which is run faster. The following formula can be used in practical application.

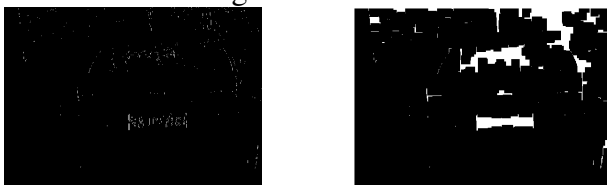
$$g(x,y) = \left\{ \left[f(x,y) - f(x+1,y+1) \right]^2 + \left[f(x+1,y) - f(x,y+1) \right]^2 \right\}^{1/2} \quad (6)$$

In the type, *f(x, y)* stands for input image; *g(x, y)* stands for output image. As the image shown in Figure 2(c) is the output image.

Determine the candidate regions of plates

Morphological processing: Before morphological image processing needs binarization. This paper selects large law Otsu binary image processing [6], thus better able to determine the image pixels is background or objective, as the result shown in Figure 2(b).

After edge detection and binarization processing, the edge of the vehicle is well extraction. However, due to the impact of environmental, the plate is not easy to detect because of these regions are always not closed. Therefore requires a series of morphological processing, in order to confirm the vehicle candidate areas. The mathematical morphology basic operations include: Erosion, Dilation, Opening operation and Closing operation. In this paper we use the Erosion and Closing operation, as the results shown in Figure 3.



(a) Erosion (b) Closing operation

Fig.3. Vehicle morphological image processing

At first, setting the structural element size according to experience and use this structural elements for image erosion operation. Thus it can eliminating the boundary points in the target image. At the same time, we can remove some small and insignificant outlier, see Figure 3(a). Then use closed operations to integrated narrow gap and remove the hole, get some regular shape connected regions, as the results shown in Figure 3(b).

It is easy to form many isolated connected domain in the image when the background is complicated. And these small plates are obviously not connected domain area In order to reduce the computational of the algorithm, you can use the projection method to remove the smaller regional connectivity in the images that have been using morphological image processing. After deleting these connecting regions, the remaining areas are the region need to identify. With aspect ratio, size, projection characteristic values to indicate these areas. Then based on the value of the width and horizontal distance, calculate the strength of connection of the two candidate areas. Connection strength *I* is calculated as follows.

$$I = \frac{ORV}{(h_1, h_2)^{1/2}} - \frac{DisH}{\max(\omega_1 / \omega_2)} \quad (7)$$

In the type, *ORV* stands for the vertical height of the two candidate regions; *DisH* represents the horizontal distance between the two candidate regions; $h_1, h_2, \omega_1, \omega_2$ respectively represent the height and width of the two candidate areas. The two candidate regions prefer the same region if *I* have a larger value. This allows the separation of regions from the original image of the license plate belong to re-incorporated into the license plate area.

License plate image positioning

After a series of processing on the license plate image we have obtained some candidates regions. In evaluating the characteristics of the candidate regions, we based on the inherent characteristics of the license plate, such as license plate aspect ratio, the size of the license plate area, shape and other characteristics of the area. Compare the candidate region with the ideal plate area, filtering the candidate regions.

To restrain the imaging noise, usually we use the low-pass filter. However, since the edge contour contains a large amount of high frequency information, although the low-pass filter filtering the noise but also blurs the boundary. In order to filter the noise while preserving edge contour information well we use the median filter. The principle of median filter is using a window W to scan on the image. Grayscale image pixels are arranged in ascending or descending. Original image pixel gray value is taken as the center of the gray value pixel. Thus the median filter will be completed. The key effect of the median filter processing is to select the window W. In this paper, the median filtering window is a square window and the window contains nine pixels. This median filter is useful in eliminating the interference of isolation noise points. More important is the use of such windows can be effectively protected the boundary information.

Conclusion

According to the algorithm above on, we tested 200 license plate images shot in a variety of environments. License plate location simulation results statistics for different situations see Table 1.

Table.1. Statistical data in license plate location test results

Environment	Simulation picture	Successful	Accuracy rate
Regular(Sunny)	86	84	97.67%
Regular(cloudy)	57	55	96.49%
Randomly(Sunny)	36	33	91.67%
Randomly(cloudy)	21	15	71.42%
Total	200	187	93.50%

The vehicle license plate was located in a different scene, the results shown in Figure 4.

(a) (b) (c)

Fig.4. Simulation experimental results

After analyzing the results above on, when the background is less edge information the algorithm can effectively split the vehicle area and excluding the area does not exist on the vehicle

information. Positioning speed and accuracy are more ideal. Conversely, when there is more edge information present in the image extraction effect is poor see Figure 4 (a) and (b).When the image pixel color changes more obvious the algorithms often fail to weed out certain areas that do not exist the vehicle which is seen in the Figure 4(c). Therefore, the algorithm needs further improvement in order to meet operating under various environmental conditions.

Keywords: Data warehouse; OLAP; Probability model; Data cube

Abstract. Reducing query time by means of selecting a proper set of materialized views with a lower cost is crucial for effcient datawarehousing. The database, however, needs to be utilized more, by providing a functional environment of probability analysis. The objective of this paper is to improve the effectiveness of utilizing historical cost data in an analytical OLAP (On-Line Analytical Processing) environment. The results show that the OLAP environment can help understand the uncertainties inconstruction cost estimate, and provide a way for projecting more reliable construction costs.

Introduction

From the early nineties, data warehouses have been considered to be the key aspect of success for any Decision Support System (DSS) [1].Data Warehouses (DW), Multidimensional (MD) Even now, a Databases, and On-Line Analytical Processing (OLAP) cade later, data warehouses are still seen as being the applications are used in conjunction to form a highly most important issue for the next generation of Decision.

A prototype of the cost data management environment,Cost Data Management System (CDMS), has been developed to test the advantage of OLAP in cost estimate. Here, the CDMS works as an enabler for the probability cost evaluation model described in this paper. Using the functions provided in the CDMS, the cost data stored in the data warehouse can be converted into more meaningful information for decision making.

In this paper, we will consider the following constraints when dealing with the optimal utilization of materialized views: (1) available storage space, (2) query processing effciency, and (3) the costs of DW query and maintenance. We propose effcient algorithms to optimize query effectiveness on the premise that source data might change over time. The overall time and cost of DW query and maintenance can be minimized significantly using these proposed effcient algorithms.

In our research, we use the vector data structure to determine the relationship of the lattice for the aggregate views and develop an improved algorithm to materialize an optimal pool of shared views with the lowest cost, thereby maximizing overall performance and e?ciency for queries. There are three characteristics in this algorithm. First, ‘‘metrics of gain and loss’’ and ‘‘candidateview’’ are introduced in the optimization of adding and deleting materialized views. Second, in addition to query cost, maintenance cost is also taken into account. Third, we improve the query process by adopting a vector data configuration to speed up the lattice operation in searching dependent views.

Literature review

In the construction sector, research on data warehousing and OLAP has been conducted to effectively manage the data generated during the construction process. The analytical function of OLAP, combined with the data storage capability of a data warehouse, provides an opportunity to improve data control in the construction sector. Confidence in the merit of utilizing this environment is growing due to the rapid development of construction information technologies [2].In the first step, the algorithm always chooses the materialization of the view which can be used to derive any other view. In the second step, for each view in the graph which does not yet belong to

the set of materialized views, the algorithm determines the total benefit of materializing this view. Among these analyzed views, the algorithm selectsthe view which maximizes the benefitand adds it to a materialized set. This second step is repeated until a determined number of materialized views is selected or the limit of available storage space is reached. This particular approach does not consider the maintenance cost. Ross et al. [3] considered the use of additional views to reduce maintenance cost. Liang et al. [4] proposed a two-stage algorithm that optimizes the total query response time in the first stage,and chooses views formate rialization under the given maintenance time constraint in the second stage.

In this paper, we present a cost model based on our previous work [5] to determine the desirable materialized views in which the total cost of query processing and maintenance are minimized. Yang et al. [6] used the cutting-point position of given actual storage space between candidate space and minimal space to make better decisions on determining whether to delete some candidate materialized views from the candidate space or to add more materialized views to the minimal space. Thus, we are able to develop more e?cient and effective algorithms for materialized views selection.

Multidimensional Modeling

Object-oriented multidimensional modeling. In this section, we outline the UML we use for DW conceptual modeling]. This approach has been specified by means of a UML profile which contains the necessary stereotypes for carrying out the MD modeling at the conceptual level successfully.The main features of MD modeling considered here are the relationships many-to-many between facts and one specific dimension, degenerated dimensions, multiple classification and alternative path hierarchies, and non-strict and complete hierarchies. In this approach, structural properties of MD modeling are represented by means of a UML class diagram in which the information is clearly organized into facts (items of interest for a given business) and dimensions (context in which facts have to be analyzed).

OLAP.OLAP accesses a data warehouse, analyzes data on a specific subject and accumulates them in a storage area of the data warehouse. OLAP can describe information from data analysis in a variety of formatst o provide useful information so that construction managers can make rational decisions. Thereby, the user can minimize the effort in finding and analyzing the meaning of data. The role of OLAP is increasing because it is useful for retrieving significant information by analyzing the vast volume and variety of data generated in information management systems.

Probability analysis model of cost data.

Cost data for construction work items. To explain the probability analysis method of cost data, asample of four work types, i.e. (1) cutting, (2) embankment,(3) slope protection (roll) and (4) slope protection (sheet). Five sets of historical cost data for the work items were collected from five different highway construction projects of a private company.The means and deviations of the data sets were calculated and used as unit costs. For a sample project, each work item is given arbitrary quantities. The amounts, which are the mean costs for each item, were obtained by multiplying the quantity by the mean unit cost.

Authorization objects. In this sub-section, we need to identify and specify the main objects we deal with for the conceptual modeling of DWs such as facts, dimension, classification hierarchy levels, measures, dimension attributes and instances. From now on, all the required rules for specifying security measures will be defined based on the UML stereotypes of our approach for the conceptual MD model at the conceptual level. Thus, the object component of our ACA model includes two parts:

An identity, that can be one of the following sub-attributes:

- MDClassName: The MD class identifier. It can be related to a fact class or a dimension class, referring to a fact or dimension; or base class referring to a classification hierarchy level.

- MDAttributeName: The MD attribute identifier. In object-oriented notation we have to indicate the class name, and then the attribute name. Thus, we treat both measures and dimension attributes as just attributes; since the preceding class name will tell us if we refer to a measure or a dimension attribute. Moreover, treating both measures and dimension attributes in the same way will allow us to execute security measures on attributes correctly, if in a further analysis carried out by OLAP tools, users interchange measures and dimension.

Authorization rules. Sensitivity Information Assignment Rules allow us to specify multilevel security policies, but unfortunately, these rules are not enough to specify other situations in which the access class of objects or subjects is not relevant. As we aim to define a general and expressive enough access control and audit model, we also define Authorization Rules (AURs), which exist with SIARs, thus permitting us to specify security models which are much more elaborate.In the literature, we can find different authorization variants, some of the most important being implicit, explicit, positive, negative, weak and strong. Moreover, access control models can be open (allowing access by default, unless a negative authorization exists) or closed (denying access by default, unless a positive authorization exists). In a multilevel system, a user needs to fulfill the multilevel security imposed by the object she or he wants access to, so we can consider that our system is closed. In oursystem both positive and negative AURs can coexist Some types of implicit and explicit AURs can also be defined, but we will not consider weak and strong authorizations explicitly. For each AUR, we will specify the following concepts:

- Subjects to which the rule is applicable.
- Sign, that defines if the authorization is positive(allowing access) or negative (denying access).

Conclusion

Owing to the development of construction information systems, most construction operations are conducted via digital processing, in which vast amounts of cost-related data are generated. Meanwhile, retrieval of valuable and worthwhile information from the accumulated data is a separate problem, where the use of data stored in a database has become an important company asset.

Our work for the immediate future is to improve the ACA model, extending the set of privileges considered in this paper (i.e., read), so as to permit us to specify security aspects in the crucial ETL processes for DWs, there by considering other operations such as delete,insert and update. As well as this, we plan to consider implementation issues for the use of the security aspects considered when querying a MD model from OLAP tools. This includes an in-depth study on the different combinations of dimensions, measures, hierarchies and so on, as involved in queries.

Architecting Service-Oriented Publish/Subscribe Applications: Data Model and Matching Algorithm

Biao Dong[1, a]

[1]Nanjing Institute of Industry Technology, Nanjing, China

[a]dongb@niit.edu.cn

Keywords: publish/subscribe; graph-oriented model; multimedia content

Abstract. The existing publish/subscribe(Pub/Sub) systems can't match events with subscriptions based on the semantic of events. Focusing on the production development activities, this paper presented a data model for modeling an ontology-based hierarchical description framework, defined service and its classification characteristics, and analyzed an automatic generation method of building service ontologies for the semi-structured data that exist in the Internet. A subscription matching algorithm was proposed for solving the intelligent semantic matching problem between the subscription and services. The results show that the service-oriented applications guarantee the initial and availability matching of individualized demands and service capabilities.

Introduction

Services are playing more and more important role in the modern enterprises: The enterprises provide complete solutions for customers by integrating services and products into a product service system, and are more focused on their own good while providing services to other enterprises. The traditional service oriented production process consists of the following three ways: network propaganda pattern, collaborative design pattern and commerce platform pattern. At present, the key elements to improve the modern enterprise service capabilities are advanced service business models, and service resources publishing mode.

Pub/Sub is an asynchronous communication paradigm that supports many-to-many interactions between a set of clients. A client can be an information publisher, an information subscriber, or both. Client interactions are data-centric: publishers describe their publishable events, subscribers express their interest in events, and the Pub/Sub protocol delivers the published events to their corresponding event subscribers[1]. Today, more and more enterprise services becomes available, Pub/Sub is a suitable paradigm for architecting service oriented applications. Functional requirements of Pub/Sub applications based on service contents often change, and user's needs are different, which lead to the service-oriented Pub/Sub systems efficiently publishing and subscribing remain still an open issue.

Opiyo[2] proposes a new distributed and collaborative product design concepts evaluation scheme. Globus, Condor-G and Storage Resource Broker[3,4] propose new service models that can improve the product development and design capabilities, the resource sharing capabilities. [5] proposes a cloud service model which will become the most potential service pattern in the modern enterprises in the future. The above systems mainly focus on the service model, and less involve in the whole life cycle of service model, lack the detailed definitions and quantitative descriptions of the service classification and feature attributes. It's difficult for these systems to guarantee the initial and availability matching of individualized demands and service capabilities.

In view of the above analysis, an approach, for modeling and implementing the service-oriented Pub/Sub applications, is presented. The main characteristics include two aspects as follows. Firstly, in the aspect of data model, focusing on product development, we put the resources as a service definition, define service and its classification characteristics, and analyze an automatic generation method of building the service ontology for the semi-structured data that exist in the Internet. Secondly, in the aspect of subscription matching algorithm, We construct a service-oriented

subscription model to complete the production activities. A matching method is proposed for solving the intelligent semantic matching problem between the subscription and services.

Data model

Resources. Resources are a collection of entities used in production activities, which is composed of human resources, tools, places, materials, facilities, information resources, service resources and other resources. In the paper, resources are marked Ress={resource-type-set, resource-attribute}, resource- type-set={human, tool, place, material, information, service, other}, resource-attribute= {$resources_k$, structure-attribute, ability-attribute, service-attribute}, where resource-type-set is a collection of resource types, resource-attribute is characterized by a collection of different types of resources, $resources_k$ is the k-class resources, structure-attribute={ID, name, type, location, information} is structural attributes, including resource ID, name, type, location and information, ability-attribute=(function[]) is a collection of ability attributes that represents functions of the resources, service-attribute=(cost, method, time) is a collection of service attributes that includes service cost, service method, service time.

Service and classification characteristics. Service refers to the resource that can be used, provided, and traded in the production activities, it can be released on the Internet. Service is an important basis for the Pub/Sub applications, including resources service, transaction service, process service, tool service and other services. Resources services includes the following aspects, such as information, personnel, software, design standards, databases, patents, market researches, product plans, customer need transformations, concept tests, experience conceptual models, model-making equipments, facilities, tools, physical model experiences and so on. Transaction services include reward transactions, brokered deals, bidding, auctions, online rentals, commissions and so on. Process services include project managements, resource managements, change managements, document managements, quality managements and cost controls. Tool services include software tools, real tools and so on. By using the services to abstract the user's subscriptions, we can shield the heterogeneous and dynamic characteristics of the resources. According to the user's needs, we can quickly provide ways to meet the demand, and to allocate the appropriate services to the users.

Service model. Service model SM=(task, pro-resource, ability), where task refers to production requirements, i.e., the goals needed to achieve for the completion of certain production activities; pro-resource refers to the resources needed for production processes, including personnel, tools, materials, places, tools, etc.; ability refers to the ability to achieve the desired objectives. Fig.1 shows a service model of an ontology-based hierarchical description framework. The top layer is a service ontology, which mainly includes three parts: task, resource and ability. The middle layer is the refinement on the top layer ontology, where task ontology includes goal and requirement description, resources ontology includes resources type and resources description, ability ontology includes ability type and ability description. The underlying attribute is required for the middle layer of ontology.

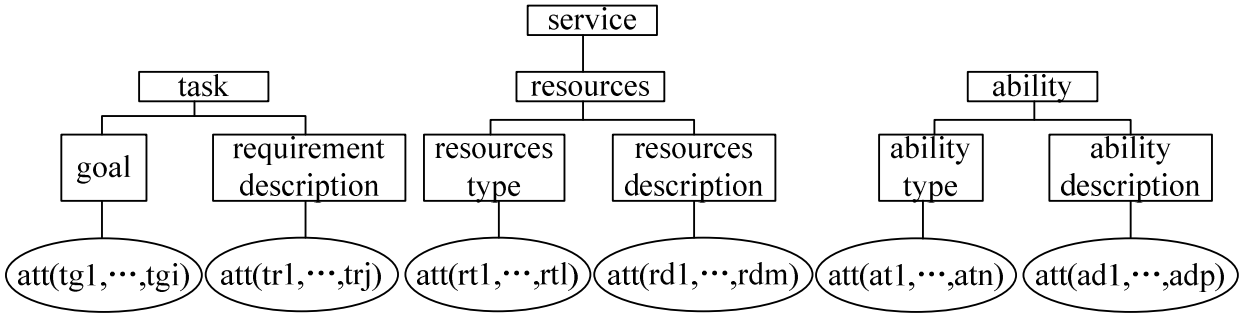

Fig.1. Service model of an ontology-based hierarchical description framework

We use web ontology language(OWL) to describe service, the detailed information of OWL resource description parameters are as follows: rdfs:Class is a set of objects with the same attributes, rdfs:subClassOf is an instance that is used to state class hierarchy, rdfs:Property states the relationship

between the expressions of individual, rdfs:subPropertyOf states attribute hierarchies that can be created by this parameter, rdfs:domain is an instance of rdf:Property that is used to state that any resource that has a given property is an instance of one or more classes, rdfs:range is an instance of rdf:Property that is used to state that the values of a property are instances of one or more classes, individual is an instance of class.

Service publishing. There is a wide variety of services, most of them exist in the internet. The establishment of services requires a large amount of the case descriptions, concepts and relationships to define the service ontologies. The contents of the service ontologies are cumbersome and complex, if all are completed by manual, it is easy to make mistakes and has a heavy workload. We study an automatic generation method of the service ontology for the semi-structured data that exist in the Internet. Firstly, we classified the resources with semi-structured format such as XML, HTML, RDF. Secondly, we perform the concept extraction and the relation extraction on the data sources, map the concepts and relations into various service ontologies, and then compare the service ontologies with domain expert ontologies. Finally, we merge the kind of service ontologies.

Matching algorithm

Subscription model. Subscription model refers to the use of external service subscriptions to complete a production. The external service subscriptions mainly include resource service subscriptions, transaction service subscriptions, process service subscriptions, tool service subscriptions and other service subscriptions. Its attributes include basic attributes, object attributes, transaction attributes and ability attributes. In the paper, Ext, Ser, Sub and Att are respectively the abbreviations of external, service, subscription and attribute. Subscription model are marked SM={Ext-Ser-Sub, Ext-Ser-Att}, Ext-Ser- Sub={Resource-Ser-Sub, Tra-Ser-Sub, Process-Ser-Sub, Tool-Ser-Sub, Other-Ser-Sub}, Ext-Ser-Att ={$Task_i$, Basic-Att, Object-Att, Transaction-Att, Ability-Att}, where Ext-Ser-Sub is a collection of external service subscriptions, Ext-Ser-Att is a collection of service attributes, and $Task_i$ is the i-class task. Fig.2 shows characteristic attributes of a subscription model. For simplicity, Transaction-Att and Ability-Att are collectively referred to as service attribute(Ser-Att) in Figure 2.

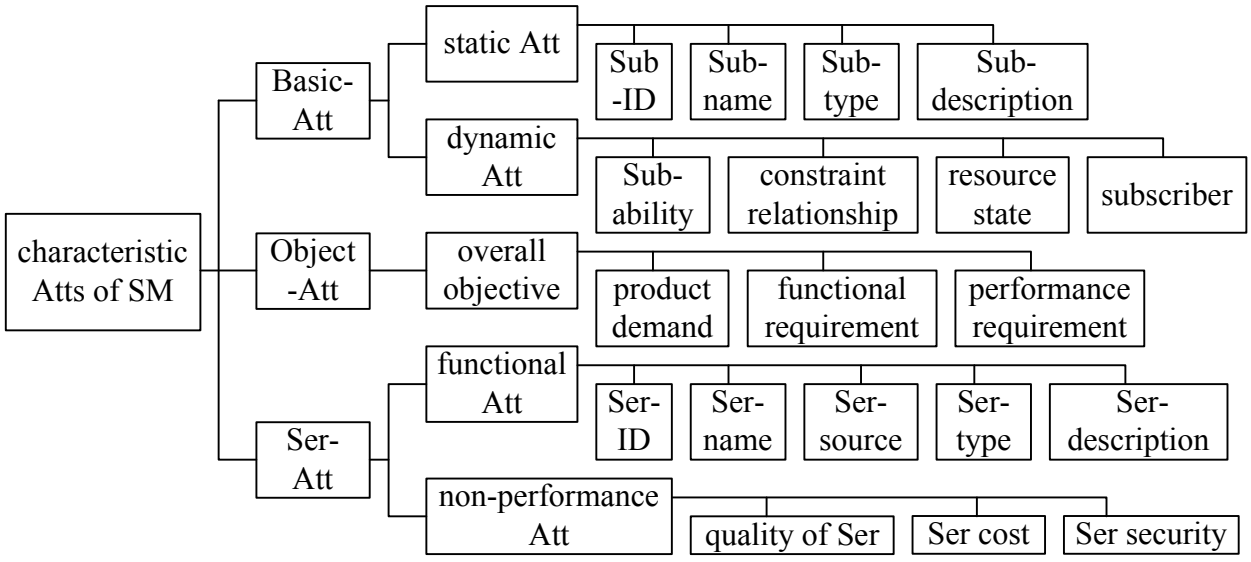

Fig.2. Characteristic attributes of subscription model

Subscription matching algorithm. The essence of subscription matching problem is that the Pub/Sub systems can quickly find all matching subscriptions after reaching a service. In order to improve the matching accuracy, the semantic matching is particularly important, it mainly solves the problem on the semantic matching between the subscription conditions and service description text. We calculate the similarity between them, and then, according to the similarity value, publish the matching service to the subscribers. Let the service ontology be a tuple SO={CC, RC, CA, CS, SS,

OI}, where CC is a set of the concepts or classes of the resources; RC is a set of relationships between the concepts, including hierarchical relationship, inclusion relationship, equivalence relationship, and so on; CA is a set of the concept attributes; CS is a value constraint set; SS is a special set which represents the disjoint descriptions; OI is a set of instances which are represented by the objects and individuals. The specific subscription matching algorithm is as follows:

(1) Analysis of a subscription vector. Let a subscription vector be $Q=\{T_1, T_2,..., T_m\}$, where T_i is the subscription feature vector which is obtained by using a segmentation method to decompose subscription conditions, its the order is determined by the corresponding weight. Let a weight set be $W=\{W_1, W_2,..., W_m\}$, where W_i is the weight of the i-th subscription feature vector, which indicates the importance of each subscription feature vector.

(2) Semantic analysis of a service vector. Let a service vector be $SV= (RC_1, RC_2,..., RC_n)$, where RC_i represents the i-th service object vector, which comprises multiple attribute values, and satisfies the equation $OI=CC \cup RC \cup CA \cup CS \cup SS$. Let the service description vector be $P=\{CA_1, CA_2,..., CA_m\}$, where $P \in RC_i$; CA_i is the heavily weighted attribute, its the order is determined by its weight.

(3) Subscription matching. Matching rules between each component of the service description vector and the corresponding component of the subscription vector are as follows: if $CA_i=T_i$, then $K_i=1$; if T_i satisfies CA_i, then $K_i=K_m<1$; if T_i contains A_i, then $K_i=K_c<1$; if T_i is completely separated from CA_i, then $K_i=0$.

(4) Getting subscription candidate set. Similarity measure for comparing P and Q is defined as follows: $Sim(P,Q) = (\sum_{k=1}^{n} K_i \times W_i) / \sqrt{(\sum_{k=1}^{n} W_i^2)}$

If Sim(P,Q) is greater than a threshold, the candidate set of subscriptions is denoted by $D=\{D_1, D_2,..., D_m\}$, otherwise, there isn't the candidate set of subscriptions. According to the constraint conditions, the D is matched to meet the target function. we obtain the optimal subscription set D_x, where the number of elements in the D_x is less than the number of elements in the D.

Conclusions

We model the service-oriented Pub/Sub architecture. In our future work, we plan to establish a development environment by integrating the infrastructure, the executing environment, and the ontology engineering tools to provide a profound basis for the seamless integration of ontological knowledge to unleash its full potential for efficient service oriented Pub/Sub applications.

Keywords: CUDA; K-Means algorithm; CURE; MMPI

Abstract. This paper analyzed the employees' MMPI Psychological data of a company. Aiming at the problem that traditional K-Means algorithm is sensitive to the initial clustering center, this paper used hierarchical clustering algorithm CURE to mitigate the problem. Finally using CUDA technology clustered several times, so as to improve the execution efficiency of the algorithm. Through experimental verification, the improved K-Means algorithm behaved well in both execution efficiency and clustering results.

Introduction

Cluster analysis is often used to divide the data into useful or meaningful groups or clusters, and plays an important role in psychology, biology, statistics, information retrieval, machine learning and data mining. In the field of psychology, specific crowd psychology there is a corresponding feature, For such people to extract the characteristic value and cluster, can help the psychology experts to analyze the psychological characteristics of such people. K-Means algorithm as the traditional data mining methods has an important role in psychology data cluster analysis. But the traditional K-Means algorithm is sensitive to the initial cluster centers problems, leading to reduced effectiveness of clustering. For the K-Means algorithm center sensitive issues, Bradley PS and other scholars [1], presented randomly selected subsample from the data in the cluster analysis. Repeat the K-Means clustering algorithm for the selected sub-sample to get the optimization clustering center and then entire the data for K-Means clustering algorithm. However, this method is affected by the selected sub-sample collection methods, only has a sub-optimal results. For the efficiency of the traditional data mining algorithms, the application of Map reduce programming model to improve the efficiency of large-scale data clustering has become a hot spot. In fact, psychology data does not have the instantaneity, high accessibility, interactivity and large scale, therefore, using cloud platforms are not suitable for such data mining. Due to the delay of the network and its unreliability, using Hadoop platform for psychology data in the actual mining is not more efficiently than traditional methods [2-7].

CUDA is a high-performance computing technology which NVIDIA Corporation invents for its GPU (Graphic Processing Unit). This technique is ideal for psychology and other smaller-scale memory data mining, and is repeated for clustering in a limited time to observe the best results from multiple clustering results. Kumar and other scholars[8] used CUDA to achieve a Gaussian mixture model expectation maximization algorithm parallelization ,and to speed up 165 times; Zhang Fan and other scholars[9] used CUDA to calculate the length of the protein molecule, compared to CPU speedup of 7.5 times; Takahashi and other scholars[10] used CUDA accelerated three-dimensional Helmholtz equation to achieve a speedup of 23 times; Labaki and other scholars[11] applied CUDA in two-dimensional elastic potential problems and two-dimensional elastic statics problem, speedup is 56.8 and 39.6 times.

In order to solve these problems, this paper improved the K-Means clustering algorithm based on CUDA technology and FP-Tree associated iteration algorithm. Using CUDA solved the efficiency problem of multiple clusters and using hierarchical clustering algorithm CURE located the initial center of K-Means algorithm. CURE algorithm is a graph algorithm based on hierarchical clustering, the algorithm use graph approach to achieve the initial data divided. And use inter-cluster proximity, connectivity concepts and part of cluster to model. Found high quality clusters of different shape and size and density [12]. So in this paper, we preliminary cluster the memory data to achieve the initial parameters for K-Means algorithm, and use CPL clustering algorithm to ease the instability problem which the randomness and apriority of K-means initial clustering center lead to the result . In the implementation of the results of K-Means algorithm, using the FP-Tree for several clustering results association analysis can reduce central K-Means algorithm sensitive issues and improve the effectiveness of clustering.

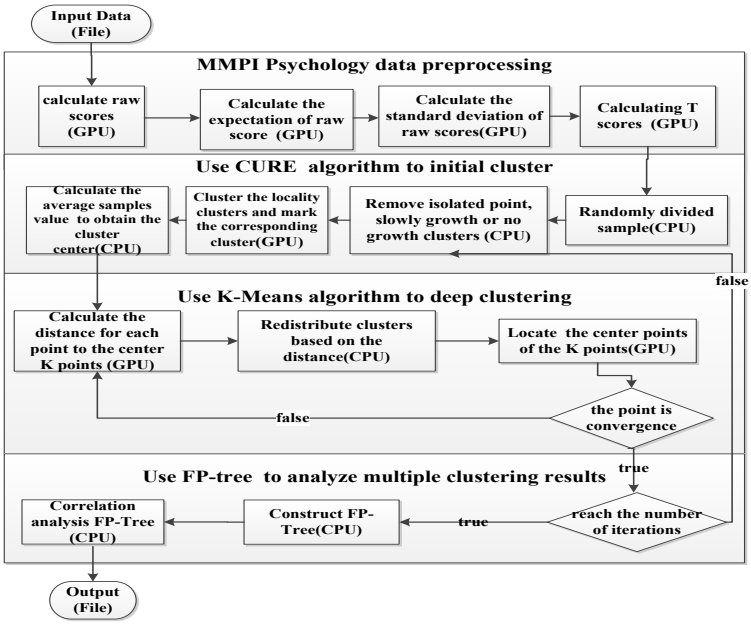

Figure 1: Improved K-Means algorithm framework

The data stream in the GPU use CUDA technology to accelerate computing, and use .NET Framework platform for IO read and write and task processing in the CPU.

Preprocessing of psychology data

This paper used the MMPI (Minnesota Multiphasic Personality Inventory) scale sets in the behavioral psychology to gather the behavioral psychology data of people in a company. Clustering crowd to help psychology researchers analyzed population Multiphasic Personality. MMPI is the most complex and cumbersome behavioral of a test of psychology, but its accuracy is more accurate than other scales [13]. The first step of MMPI is to get test data, calculated for each test object 25 test items raw scores, two scales, and a total of 566 test questions. Due to the number of each test questions is difference, leading to total scores different, cannot be directly compared ,we need to normalize the raw scale scores. The second step is required by equation (1)

$$T = 50 + 10(X - M)/SD \tag{1}$$

to calculate for each sub-scale normalized to a standard ***T***. ***T*** is a vector, each component of the vector represent each scale's standard score. ***X*** is a raw scores vector consists of each raw scores of psychological questionnaires. ***M*** is the normal vector of each test scale raw score composed expectations. ***SD*** is the normal vector of each test scale raw score standard deviation. MMPI data preprocessing focuses on the raw scores converted to standard ***T*** points. Calculate its expectation ***M*** and standard deviation ***SD***.

Computing the standard deviation ***SD*** and expectation ***M*** in the host requires multiple iterations, and iterative scale increases with the data size increases. In the same scale data, using CUDA technology transform the iterations into parallel execution, thereby reducing the scale of the iteration to improve the efficiency. In the CUDA parallel environment, using the reduced tree algorithm calculate the expectation ***M*** and standard deviation ***SD***, as shown in Figure 2.

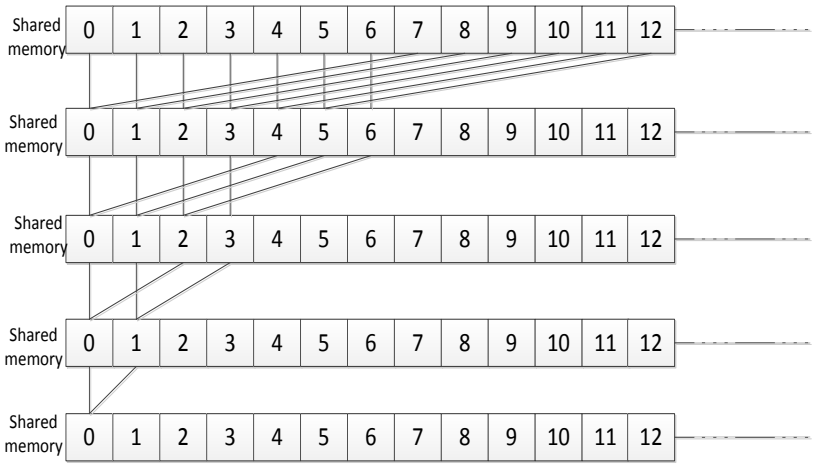

Figure 2：Reduced tree algorithm

In Figure 2, using reduced tree algorithm parallel add for a test scale raw score of the first 13 test through 5 iterations and store the result of the addition in the first element of the shared array. The result divide the length of the array can achieve the expectation M of this test.

Using CUDA improve CUDA algorithm

CURE[14] algorithm is a clustering algorithm based on hierarchy, which is different from the traditional method that use one object to represent the cluster, instead of using multiple objects, and through the shrinkage factor to regulate cluster shape, as a result, it can deal with non- spherical distribution or size of uneven distribution of cluster, and has a good effect on treatment of isolated points, so in this paper psychology data use the CURE algorithm to initializing clustering, to get the input parameters of K-means algorithm: the number of clusters and the corresponding initial class centers, so as to reduce the clustering fluctuation problem of randomness and apriority of K-means initial clustering center. The key to CURE clustering is to calculate the distance between samples, the distance between the samples can form as a matrix, using CUDA read matrix into the device memory. Using CUDA thread, respectively calculate the distance of sample points. As shown in the matrix:

$$\begin{bmatrix} d_{11}, d_{12} & \cdots & d_{1n} \\ \vdots & \ddots & \vdots \\ d_{n1}, d_{n2} & \cdots & d_{nn} \end{bmatrix} \tag{3}$$

The described matrix is the distance between the sample points. The d_{11} represents the distance the first point to itself, d_{12} represents the distance of the first sample points to the second sample point, by analogy, d_{nn} represents the distance the ***n*** point to itself, this matrix is a triangle or lower triangular matrix.

Use CUDA to improve the K-Means algorithm

The improved K-Means algorithm has two stages, the first stage is to find the ***K*** centers, and calculate the distance between other point and the center of ***K***, put the nearest point of the center constitute k clusters. The second phase is to calculate the center point of K clusters, as the initial

center point of the first stage of next iterative, iterate until convergence center point to a threshold range. Since this paper use CUDA algorithm to find the initial center of K-means algorithm, so the first phase focuses on CUDA technical computing ***K*** center point to another point distance. This phase also relates to matrix operations, so using CUDA technology to accelerate this process. In the CUDA device memory, Let n be the vector the length of the array ***R***, let ***K*** be the length of center point vector array S, compose ***n*** × ***k*** matrix ***H***, Unit matrix ***H*** (***i***, ***j***) represents the distance in the vector array with the vector ***Ri*** and ***Sj*** central vectors. The distance metric function is $\frac{f_{11}}{\sqrt{f_{1+}f_{+1}}}$. As shown in figure 3.

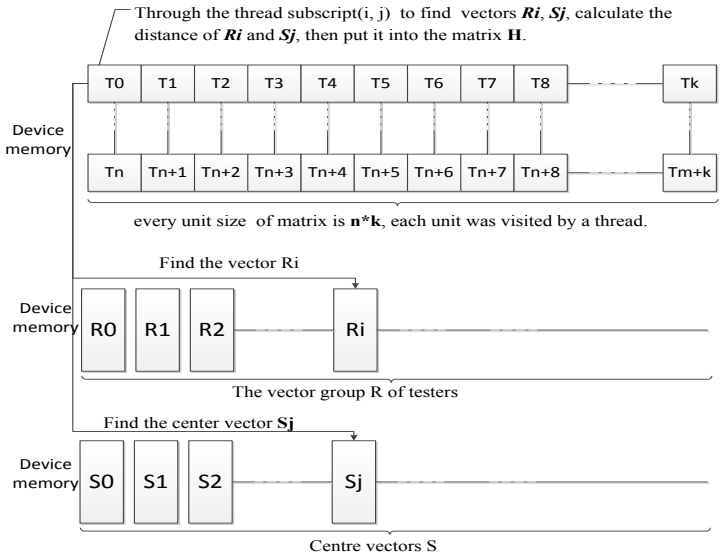

Figure 3：Calculate the distance of each vector group in ***R*** and ***K***

The matrix ***H*** is copied from the device memory back to the host memory. Iterate array ***H***. And find vectors ***R1~k*** nearest to the centers vector ***K*** respectively, and compose ***K*** clusters.

Construct FP-Tree Data Structure

Running the CUDA algorithm and the K-Means algorithm for several times compose transactional data. Format and data are shown in figure 4.

Figure 4：Transactional data format (Part of the data)

Each row is a cluster, each test number separated by commas, in ascending order, preparing for the construction of FP-tree. Add the several clustering results to the same file, and compose transactional data. For the following three reasons: 1, CUDA algorithm k value is artificial selection; 2, ***In RI×RC > u***, ***u*** threshold is artificial selection too; 3, K-Means algorithm center iteration convergence instability. Because the results of these clusters has led to instability, so you

can use correlation analysis of FP-tree algorithm to find frequent item sets in multiple clustering results to reduce instability.

Experiments

Experimental environment: CPU: Intel i7-3770; CPU frequency: 3.4GHz; CPU cores / threads: 4/8; Host Memory: 8GB; GPU: NVIDIA GTX 660; Device memory (graphics): 2GB; CUDA version: 5.0; Operating system: Windows7.

Experimental data: In this paper, experimental data is MMPI psychology test data of the employees in a company over the years. Size is 353MB, unit is line, and test data have 907,689, and composed of five .csv file.

Experimental Analysis

Compare the improved K-Means algorithm execution efficiency in CUDA parallel accelerated environmental and pure CPU serial execution environment.

In order to compare the performance of the algorithm, we compare the various parts of the improved K-Means algorithm execution in CUDA (in the following table are referred to as parallel speedup environment) and pure CPU execution environment (in the following table are referred to as a serial environment), and using speedup ratio measure the efficiency of the algorithm. Data preprocess results shown in table 1.

Table 1: Data preprocessing results

CPU IO read and write T consuming time /ms	Serial environment CPU consuming time /ms	Parallel CPU acceleration environment consuming time /ms	Parallel GPU acceleration environment consuming time /ms	speed-up ratio
136871	113780	8452	2675	39.37

As apparent from table 1, in serial CPU environment computing MMPI T scores in time mainly used for its expectations and standard deviation calculations, In the parallel accelerate environment to compute expectation and standard deviation T scores in the GPU, IO read and write files is the main work of CPU, and use the preprocessing of the algorithm computing part for CUDA parallel computing, and the ratio of the accelerated procedure has greatly improved.

When $\boldsymbol{RI \times RC}$ threshold increase, both the serial environment version and parallel acceleration version of CUDA algorithm appear decline situation. After analysis, the serial version of CUDA algorithm environment not only need to traverse k nearest neighbor diagram in the first phase and traverse the nearest clusters in the second stage of the algorithm, but also need to calculate the lower triangular matrix elements of the first phase and the second phase consisting of vectors cluster lower triangular matrix elements. After the CUDA algorithm is parallelized by CUDA , mainly parallel part is to calculate the lower triangular matrix of two stages, but traversal k nearest neighbor graph and the nearest cluster is still performed in the CPU environment, and agreed with the algorithm serial performs partial . With RI×RC threshold increases, the cluster meet the conditions to merger reduced, the consolidation process takes time becomes less too. That is to say serial and parallel acceleration environment version of the algorithm traversal part time cost will reduce.

We can conclude, with the larger the initial number of clusters $\boldsymbol{K}$, the K-Means algorithm acceleration ratio is increased. After analysis, two stages of K-Means algorithm for the calculation of each point to center point distance and finding central point to improve CUDA parallelization. All the numerical in the algorithms are run on the GPU, CPU for data copy and scheduling such that the efficiency of the algorithm is greatly improved, especially in the case of the many initial clusters, the speedup ratio also rapidly increase.

When $\boldsymbol{RI \times RC}$ threshold increase, K-Means clustering initial number $\boldsymbol{K}$ increase too. This has resulted increased size of K-Means algorithm calculation, the speedup ratio also increased. It can be

concluded, when using the improved K-Means algorithm to calculate the size and amount of data increases, the efficiency of the algorithm become higher.

Experiments using three authority data sets UCI machine learning database to test. The data are Iris, Wine and Glass. As shown in table 2.

Table 2： Data and Statistical information

Dataset	Number of sample	Number of categories	Number of attributes	Category Distribution
Iris	150	3	4	50,50,50
Wine	178	3	13	59,71,48
Glass	214	6	10	70,67,17,31,9,92

In this paper, purity standards are regarded as effective method to evaluate the clustering results. Let the class size of the cluster ***Ci ni***, this cluster of purity class definition equation (4) ：

$$P(C_i) = \max_i(n_i^j)/n_i \tag{4}$$

Ci represents the intersection of the first ***j*** class size. n_i^j represents the intersection size of ***Ci*** and class ***j***.

Equation (5) ：

$$\text{Purity} = \sum_{i=1}^{k} \frac{n_i}{n} \max_i(n_i^j)/n_i \tag{5}$$

Equation is the results of clustering purity. ***k*** is the number of clusters formed, the higher the purity, the more effective the clustering algorithm. In this paper, set the iteration parameters of the improved K-Means algorithm to 50 times, correlation analysis the FP-Tree in this clustering results in 50 times, to get the final clustering results. The operating results of the improved K-Means algorithm are better than the traditional K-Means algorithm.

Conclusion

In the memory data, using CUDA technology could improve the memory data processing and analysis efficiency well. In the experiment of clustering the psychology MMPI data sets, the improved K-Means algorithm executed several times within an acceptable period of time. With the increase of the number of iterations, the purity of the clustering algorithm also increased, in other words, the execution efficiency improving support the purity of the cluster improving. The improved K-Means algorithm is applied to a psychology test system of a company; clustering analysis the MMPI data of employees help psychologists to accurate test personnel division, have achieved the expectant effect.

Keywords: LTE-Advanced; Coordinated Beamforming; Cell Selection

Abstract. In LTE-A (LTE-Advanced) system, CoMP (Coordinated Multipoint Transmission) is used to improve system capacity and cell coverage. CB(Coordinated Beamforming), as a way of CoMP, using multi-cell coordination to improve the spectrum efficiency of edge users. Therefore, coordinated cell selection is important. To achieve better performance, multiple factors rather than a single one are considered in cell selection, channel gain as well as cell load is taken into account in the article. Multiple factors constitute a matrix to find the optimal coordinated cells, multi-objective optimization is used here. Simulation result shows system performance of the proposed algorithm is better than the one only considers channel gain.

Introduction

LTE system adopts OFDM technique, in which subcarriers are orthogonal. As a result, users are protected from interference from other users in the same cell. In LTE-A system, MIMO(Multiple Input Multiple Output), which could break the Shannon limit, is adopted to improve system capacity. However, with a long distance from serving BS, signal power received by cell edge users is low, edge users suffer from the same frequency interference, and the spectrum efficiency is low. To solve the problem, CoMP(Coordinated Multipoint Transmission) is used, that is, multiple coordinated cells constitute a virtual MIMO system. CoMP has two patterns, JT(Joint Transmission) and CB(Coordinated Beamforming). The coordinated cells change CSI(Channel State Information) and user data by X2 port. In JT system, all the coordinated cells transmit data to UE, aimed at transforming interference to useful signals. In CB system, only serving cell transmit data to UE, all the coordinated cells share channel state information by X2 port, to shape the beamforming vector. Compared to JT, CB has less backhaul and higher spectrum efficiency. This article is based on CB system.

As the performance improvement of edge users rely on cell coordination, and only serving cell transmit data to users in CB, the signal strength received by UE depends on the channel state quality from BS to UE. Therefore, coordinated cells and serving cell selection could affect the quality of received signal. Reference [1] proved that the number of coordinated cells to achieve optimal performance is three, without extra complexity. Reference [2] presented that the coordinated cells could be three or less, which could improve the spectrum efficiency when a few channels' state is not good. Reference [3] [4] [5] concerned cell selection based on one standard RSRP. Reference [6] proposed a cell selection algorithm considering multiple factors, RSRP and latency time, which achieved good system performance in different traffic model. This article proposed a new cell selection algorithm takes RSRP, interrupt rate, fill rate into consideration at the same time, and select the optimal serving cell by calculating the distance between different channel factors and the factor extreme value.

Coordinated Beamforming Model

In CoMP system, adjacent cells serve one UE to improve the performance of cell edge. In CB, coordinated cells share channel state information by X2 port and the serving cell transmit data to UE. The system model is shown in Fig. 1. The black arrow represents data transmission, the black line represents channel state information change by X2 port. Consider the k th user in cell 1, suppose the data transmitted from BS to the UE is s_k, then the data received by the k th user is

$$y_k = H_k^k W_k s_k + \sum_{i,i\neq k} H_k^i W_l s_l + n_k \quad (1)$$

H_k^i represents the channel matrix from cell i to UE k, W_k represents the beamforming vector from cell i to UE k, the second part in the right of the equation represents interference from other cells to UE k , n_k represents Gauss noise received by UE k, with mean value 0 and variance σ^2 .

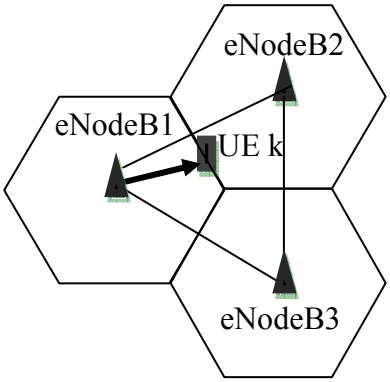

Fig. 1 Coordinated Beamforming model of three cells

The SINR of UE k is

$$SINR = \frac{\left\| H_k^k W_k \right\|^2}{\sum_{i,i\neq k} \left\| H_k^i W_l \right\|^2 + \sigma^2} \quad (2)$$

The optimal beamforming vector can be obtained by the algorithm in Reference [4]

$$W_k = \max eigenvector((\sigma^2 I + \tilde{H}_k^H \tilde{H}_k)^{-1} H_k^H H_k) \quad (3)$$

$\tilde{H}_k = [H_1 \quad H_2 \quad \ldots \quad H_{k-1} H_{k+1} \quad \ldots \quad H_l]$, $(.)^H$ represents conjugate transpose of $(.)$.

Cell selection Algorithm Design

Consider seven adjacent cells in Fig. 2. To cell 1, the other six cells are interference cells as well as candidate coordinated cells. Users distribute in every cell randomly. BS of each cell is equipped with M antennas, while every UE has N antennas. Edge users and center users are distinguished by signal fading value, usually cell radius ratio is used.

$$PL = -(32.23 + 35.04 \times \log(10 \times (R \times ratio))) \quad (4)$$

R represents cell radius, *ratio* is the radius ratio. If signal fading value received by UE is large than the ratio, the UE is edge user, otherwise the UE is centre user. Centre user is served by the cell it belongs, edge user require cells coordination.

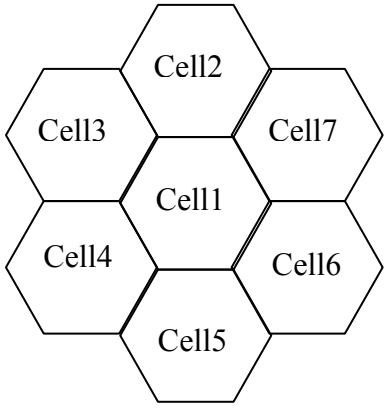

Fig. 2 Seven cells interference model

Cell selection for edge users generally based on RSRP [5]. The algorithm is convenient and could achieve good result when user's location is fixed and different users' requirement is equal.

However, if users don't distribute uniformly, several cells' capacity may be full, the RSRP selection algorithm would lead to users failing to join the cell or service interrupt. Therefore, multiple factors should be taken into account when select the serving cell . Consider three factors below:

A. SNR received by UE, which could reflect channel gain from BS to UE.

$$SNR_{receive} = \frac{P_t * A_{antenna} * P_{loss} * Shadowing}{N_0} \tag{5}$$

P_t is the transmitted power of BS, $A_{antenna}$ represents antenna gain, P_{loss} is path loss, *shadowing* is shadow loss, N_0 is the power of noise.

B. User's interrupt rate. When a user join a cell, the cell load should be considered, interrupt rate is used here [7]. The interrupt rate of UE k joined in cell j is

$$\alpha_{k,j} = \frac{O_j}{N_j} \tag{6}$$

N_j is the number of subcarriers in cell j , O_j represents the amount of occupied subcarriers in the cell. The maximum value of interrupt rate is 1, the minimum value is 0. The less the value is, the cell is more appropriate to be joined.

C. User's fill rate. With different requirement of users, the amount of subcarriers used is different. Define UE fill rate to indicate the cell could satisfy the joined users or not. The fill rate of UE k in cell j is

$$\beta_{k,j} = \frac{G_j}{M_k} \tag{7}$$

M_k is the number of subcarriers UE k needs, G_j is the number of subcarriers cell j allocates to UE k. The maximum value of fill rate is 1, the minimum value is 0. The more the value is , the more available the cell has, the more suitable to join for UE .

Upon on the factors given above, using fuzzy multi-objective decision making theory, propose the cell selection algorithm below:

1) Confirm candidate coordinated cell set. Here 7 adjacent cells model is adopted.

2) Using the three factors of candidate cells to form a matrix X.

$$X = \begin{bmatrix} x_{11} & x_{12} & x_{13} \\ x_{21} & x_{22} & x_{23} \\ \vdots & \vdots & \vdots \\ x_{71} & x_{72} & x_{73} \end{bmatrix} \tag{8}$$

x_{ij} is the ith factor of cell j. SNR and fill rate are positive factor, which means the more the better, while interrupt rate is negative factor, which means the less the better. Normalize the two kinds of factors as:

$$x_{ij} = \frac{x_{ij} - \min\limits_j x_{ij}}{\max\limits_j x_{ij} - \min\limits_j x_{ij}} \tag{9}$$

$$x_{ij} = \frac{\max\limits_j x_{ij} - x_{ij}}{\max\limits_j x_{ij} - \min\limits_j x_{ij}} \tag{10}$$

3) Give the factors weight value

$$W = diag[w_1, w_2, w_3] \tag{11}$$

then

$$R = X * W = \begin{bmatrix} r_{11} & r_{12} & r_{13} \\ r_{21} & r_{22} & r_{23} \\ \vdots & \vdots & \vdots \\ r_{71} & r_{72} & r_{73} \end{bmatrix} \tag{12}$$

4) Calculate the maximum value of factors, which is the perfect value

$$R_j = \max_j r_{ij} \tag{13}$$

5) Calculate distance between r_{ij} and R_j, and obtain the sum value

$$C_i = \sqrt{\sum_{j=1}^{n} (r_{ij} - R_j)^2} \tag{14}$$

6) Order C_i in ascending dimension, [C'_1 C'_2 …C'_7], then cell C'_1 is the serving cell.

7) Select the first two cells which interfere the serving cell most serious as coordinated cells. As a result, interference received by UE could be suppressed. The standard here is RSRP feedback by UE. Then do Coordinated Beamforming to the users in coordinated cells.

Simulation result

The Coordinated Beaforming algorithm based on RSRP cell select and based on the proposed algorithm are simulated. Simulation parameters are shown in Table I.

TABLE I Simulation Parameters

Simulation parameters	Value
Cell radius	1000m
System bandwidth	20MHz
Carrier spectrum	2GHz
BS antennas	2
UE antennas	2
Channel model	3GPP SCM
Shadow loss	$u = 0, \sigma = 10dB$
Path loss	$128.1 + 37.6\log_{10}(r)dB$
BS transmit power	46dBm
Noise coefficient	9dB
Transmit antenna gain	14dBi
Channel estimate	ideal

Compare two algorithms in system capacity, edge spectrum efficiency and user's fill rate. Fig. 3 is system capacity, the two algorithms have similar performance. The reason is, the proposed algorithm is focused on edge users, whose amount is much more less than centre users, as well as proportion of system performance.

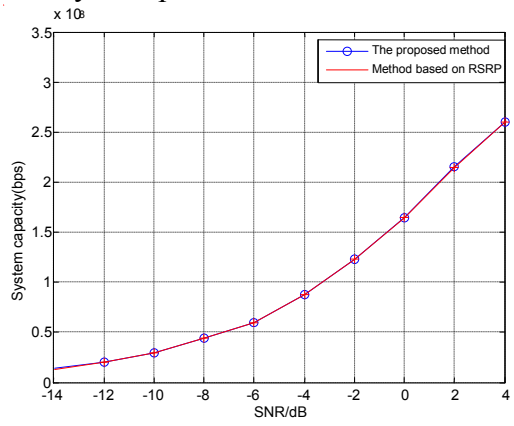

Fig. 3 System capacity

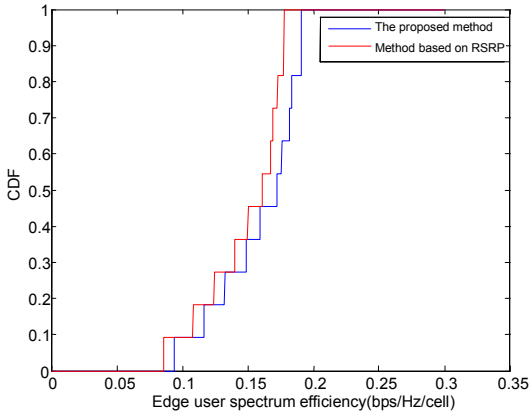

Fig. 4 Edge spectrum efficiency

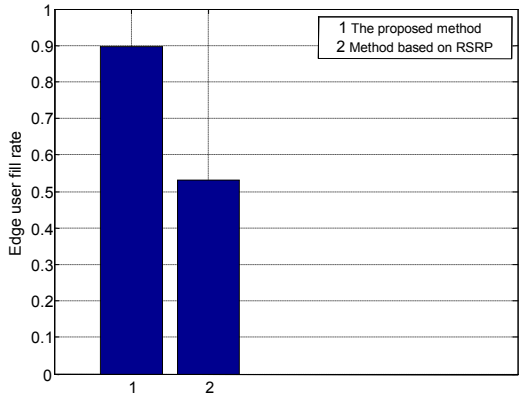

Fig. 5 Edge users' fill rate

Fig. 4 indicates edge spectrum efficiency of two algorithms, the proposed algorithm has taken cell load into account, which could select the optimal cell for UE to join, its performance is better than the one of the RSRP. Fig. 5 is the fill rate of the two algorithms. As the proposed one considers users' fill rate, and make it a standard of cell selection, the fill rate performance is much better than the RSRP algorithm.

Conclusion

Based on Coordinated Beamforming in LTE-A, cell selection algorithms are studied. An improved algorithm based on the RSRP cell selection algorithm is proposed, which considers multiple factors , RSRP, interrupt rate and fill rate. Using multi-objective select model to calculate the optimal cell for UE to join, then select coordinated cells. Simulation result demonstrates the proposed algorithm has better performance than the traditional one in edge spectrum efficiency and users' fill rate.

Keywords: MIMO-SAR; sub-band synthesis; range resolution

Abstract. Multiple-Input and Multiple-Output Synthetic Aperture Radar (MIMO-SAR) can achieve high resolution and wide swath at the same time, which has a wide horizon of development in the future. An azimuth frequency-diversity MIMO-SAR is presented, and overlapped effective phase center sampling is obtained while the pulse repetition frequency (PRF) is appropriate. This paper derives an improved sub-band synthesis algorithm which reduces the complexity of conventional sub-band synthesis algorithms and improves the range resolution. The feasibility of this imaging algorithm is proved by point target simulation experiments.

Introduction

The capability of high resolution and wide swath imaging [1] is desired by space based remote sensing and military reconnaissance. But there is an irreconcilable conflict between azimuth resolution and swath in conventional SAR because of minimum antenna area constraint [2]. This conflict can be mitigated by MIMO-SAR. With the same azimuth resolution, it can achieve much wider swath than conventional SAR due to the reduction of PRF. sub-band synthesis algorithm can improve the range resolution while effective phase center sampling is overlapped. A sub-band synthesis algorithm is presented in [3], however, it is complex.

In this paper, an azimuth MIMO-SAR configuration using frequency-diversity is presented. Comparing with conventional SAR, it can reduce the PRF with the same azimuth resolution, the reduction of PRF can widen the width of the swath. Then a new sub-band synthesis algorithm is derived. This algorithm reduces the complexity and improves the range resolution. So the capability of high resolution and wide swath imaging is obtained [4]. Some results of the point target simulation experiments are given. Finally, the conclusions are drawn.

Configuration of the Azimuth Frequency-diversity MIMO-SAR

To illustrate the azimuth frequency-diversity MIMO-SAR, we assume a SAR system with five apertures as shown in Fig.1, where the platform moves with velocity v_p at an altitude h. In a pulse repetition interval, the 2nd aperture, the 3th aperture and the 4th aperture transmit linear FM pulse with different center frequency. the 1st aperture and the last aperture receive the echo signal. The equivalent receiving phase center is located at the middle point from the transmitting aperture to the corresponding receiving aperture [5]. As long as the difference between carrier frequencies is larger than the signal bandwidth, the received signals can be separated via bandpass filters.

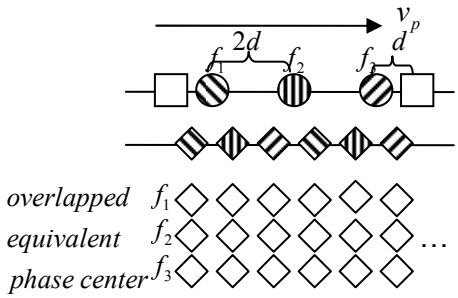

Fig.1 Configuration of the azimuth frequency-diversity MIMO-SAR

In order to achieve overlapped uniform sampling in the azimuth direction, as shown in Fig.1, the radar must be operated with an appropriate PRF [6]. Overlapped uniform sampling is obtained, when the PRF satisfies:

$$PRF = \frac{v_p}{2d} \tag{1}$$

Improved Sub-band Synthesis Algorithm

The previous section presents a structure of the azimuth frequency-diversity MIMO-SAR, the transmitting signal bandwidth is B, In this paper, we assume $f_m=f_1+(m\text{-}1)B$, so that the received signals can be separated effectively via band-pass filters . After bandpass filtering and frequency conversion, the received baseband signal of the mth overlapped equivalent aperture is:

$$\begin{aligned} x_m(\tau,t) &= rect\left(\frac{\tau-2R_e(t)/c}{T_1}\right)\exp\left(-j4\pi f_m R_e(t)/c\right) \\ &\cdot\exp\left(j\pi k_r\left(\tau-2R_e(t)/c\right)^2\right) \end{aligned} \tag{2}$$

Where τ is the range time, t is the azimuth time, k_r is the azimuth FM rate, T_1 is the duration of the transmitted pulse, *rect*( ) is the rectangular function and $R_e(t)$ is the range from the equivalent phase center to the target.

Next we will derive the improved sub-band synthesis algorithm. At first, frequency spectrum shift operation is done by multiplying a frequency spectrum shift function, the function is given as follow:

$$v_m'(\tau) = \exp(j2\pi(m-2)B\tau) \tag{3}$$

And the result after frequency spectrum shift operation is:

$$\begin{aligned} x_m'(\tau,t) &= x_m(\tau,t)v_m'(\tau) \\ &= rect\left(\frac{\tau-2R_e(t)/c}{T_1}\right)\exp\left(j\pi k_r\left(\tau-2R_e(t)/c+(m-2)T_1\right)^2\right) \\ &\cdot\exp\left(-j4\pi f_c R_e(t)/c\right)\exp\left(-j\pi k_r((m-2)T_1)^2\right) \end{aligned} \tag{4}$$

Then do Fourier transform in range direction and transform to the frequency domain, the result of Fourier transform is:

$$\begin{aligned} x_m'(f_r,t) &= rect\left(\frac{f_r+(m-2)B}{B}\right)\exp\left(-j\pi\frac{f_r^2}{k_r}\right)\exp\left(j\pi f_r(m-2)T_1\right) \\ &\exp\left(-j4\pi(f_c+f_r)R_e(t)/c\right)\exp\left(-j\pi k_r\left((m-2)T_1\right)^2\right) \end{aligned} \tag{5}$$

Secondly, time shift operation is done by multiplying $v_m^2(f_r,t)$, the result of time shift operation is given in (7). we can find that the first exponential term is eliminated.

$$v_m^2(f_r,t)=\exp(-j2\pi f_r(m-2)T_1) \tag{6}$$

$$x_m(f_r,t)=rect\left(\frac{f_r+(m-2)B}{B}\right)\exp\left(-j\pi\frac{f_r^2}{k_r}\right)\cdot\exp\left(-j4\pi(f_c+f_r)R_e(t)/c\right)\exp\left(-j\pi k_r\left((m-2)T_1\right)^2\right) \tag{7}$$

Finally, phase correction will be done by multiplying v^3 which is given in (9).

$$x(f_r,t)=x_1(f_r,t)+x_3(f_r,t)=\left\{rect\left(\frac{f_r-B}{B}\right)+rect\left(\frac{f_r-B}{B}\right)\right\}\exp\left(-j\pi\frac{f_r^2}{k_r}\right)\exp\left(-j\pi k_r T_1^2\right)\cdot\exp\left(-j4\pi(f_c+f_r)R_e(t)/c\right) \tag{8}$$

$$v^3=\exp\left(j\pi k_r T_1^2\right) \tag{9}$$

After phase correction, we can find:

$$x'(f_r,t)=x(f_r,t)\cdot v^3=\left\{rect\left(\frac{f_r-B}{B}\right)+rect\left(\frac{f_r-B}{B}\right)\right\}\exp\left(-j\pi\frac{f_r^2}{k_r}\right)\cdot\exp\left(-j4\pi(f_c+f_r)R_e(t)/c\right) \tag{10}$$

So the signal after sub-band synthesis is given in (11), it is obvious that the bandwidth is three times wider than a single sub-band signal.

$$x''(f_r,t)=x'(f_r,t)+x_2(f_r,t)=rect\left(\frac{f_r}{3B}\right)\exp\left(-j\pi\frac{f_r^2}{k_r}\right)\cdot\exp\left(-j4\pi(f_c+f_r)R_e(t)/c\right) \tag{11}$$

After range compressing [7], according to the property of sinc function, we can find: the wider the bandwidth of the signal is, the higher the range resolution is. So the range resolution is improved.

$$x(\tau,t)=\sin c\left(3B\left(\tau-\frac{2R_e(t)}{c}\right)\right)\cdot\exp\left(-j\frac{4\pi f_c R_e(t)}{c}\right) \tag{12}$$

Simulation experiments

To validate the configuration presented in this paper, point target simulation is performed. The simulation parameters are given as follows. Center frequencies: 9.2GHz，9.5GHz and 9.8GHz, the number of sub-band signals: 3, the bandwidth of sub-band signal: 300MHz, signal pulse duration: 30 μs , radar velocity: 7600 m/s, the altitude: 514km, the length of aperture: 2.4m. Fig.2 shows the spectrum of single sub-band signal and sub-band synthesis signal. It is evident that the bandwidth of the signal is wider after sub-band synthesis, so the resolution is improved, the range resolution profiles are compared in Fig.3, the range resolution after sub-band synthesis is higher than single sub-band range resolution.

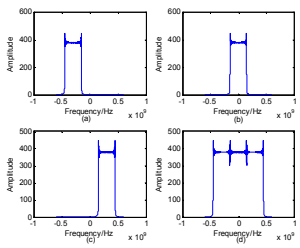

Fig.2 Frequency spectrum of sub-band signal and sub-band synthesis signal

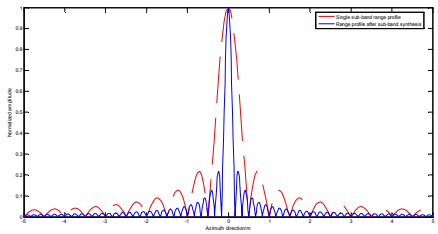

Fig.3 Range profile of single sub-band signal and signal after sub-band synthesis

Conclusion

An improved MIMO-SAR sub-band synthesis algorithm is derived. The PRF is reduced by a half compared with single channel SAR, which can achieve much wider swath. Compared with conventional sub-band synthesis algorithms, this algorithm not only improves the range resolution, but also reduces the computational load, which is of great significance in practice. However, the range cell migration is assumed to be not exceeding a range bin, so this problem is still left to be further studied.

Keywords: homology detection software; text-based; token-based; Abstract Syntax Tree; comprehensive similarity

Abstract. Software source code homologous detection is also called software copy or software clone. It is used to detect the homologous in the source code, by which we can easily find the plagiarism in the code. In this paper, it will discuss the homology detection results based on Text, Token and Abstract Syntax Tree. And will compare the three techniques and raise a model to calculate similarity by synthesizing the results. This model is based on the analysis of a large number of experimental results. Comprehensive similarity calculation model can calculate the respective contribution of the three algorithms and realize integrated computation of similarity according to this respective contribution. Finally, we can get a comprehensive similarity by this integrated similarity calculation model to make the homology detection results more accurate and closer to the actual similarity.

Introduction

Researches on the source code homology detection is very widespread, which is mainly used in software intellectual property rights detection, the software component management in the software development, especially in the clone detection in modern software engineering. Some large companies and enterprises have already introduced the source code homology detection into all the departments to detect and manage the source code, hedge the risk of intellectual property right. Of course, the research emphasis focus on the source code copy detection technology, in other words, it is also known as code clone detection. Many domestic and foreign scholars have done some respective researches on the source code copy detection technology and raised lots of algorithms. At present, the mature detection algorithms mainly concentrate on the text-based, token-based and syntax tree-based detecting techniques:

Text-based detecting technique, Due to the simple principle, text-based detecting technique is one of the earliest researches in the field of source code homology detection. Baker[1] and Johnson [2]raised the text matching technology based on the character string and the characters of the fingerprint in the text. To improve the ratio on the particle size, Ducasse[3] calculate the hash value in line for the source code and then through two-dimensional method in each hash value to compare with other hash value to get the same code line.

Token-based detecting technique, There are lots of researches on the token-based detecting technique, many comparison tools like CP-Miner[4] and CCFinder[5] have adopted this technique. This technique bases on transforming the keywords, the function name and the variable name to different token at certain rules. Then we could transform the source code which need to be detected and the benchmark source code to a set of token sequences. By comparing the two token sequences, we can find the coping parts in the source code which need to be detected.

Syntactic structure-based detecting technique, This method can not only transform the source code to Token, but also analyze and process the ATS which keeps the syntactic structure information. This technique is very widespread. Baxter[6] earlier raised the AST code homology analysis technology that can comparatively analyze the syntactic structure in the code segment to

decide whether this is plagiarized or not. In a variety of practical homology detecting techniques, AST-based technique is the most accurate[7].

As can be seen, these three detecting methods each have advantages and disadvantages. They can detect the different degree of plagiarism. But they all have some shortcomings more or less, in other words, they can't detect all the software source code plagiarism problems. The text-based method has little false rate for it detecting the source code directly, but it has a high miss rate. The token-based method can detect the plagiarism of changing names for it do the token processing on the source code, but it cannot detect the changing-order plagiarism, so it also has some miss rate. Finally, the AST-based method can not only transform the source code to token, but also can analyze the syntactic result, so it can detect the order changing plagiarism. However, on the account of too much processing on the source code in this method, we may miss some source code information. Therefore, the AST-based method has a low miss rate but a high false rate. Hence, how to reasonably use these three detecting techniques to get a similarity more closed to the real becoming the problem we want to study in this paper.

Improved Similarity Measurement Model Based on AHP

Different with the model proposed in reference [11], this paper proposed a new model which considers two indicators both of the error detection rate and miss detection rate. We also used a different method to analysis the different contribution of the three methods in miss detection rate .On the basis, get the contribution values of three methods in comprehensive similarity.

Formula of calculating codes' comprehensive similarity is:

$$Sim = w_{txt}Sim_{txt} + w_{Token}Sim_{Token} + w_{AST}Sim_{AST} \qquad (1)$$

Sim means the comprehensive similarity, Sim_{txt} means the similarity based on text, Sim_{Token} means the similarity based on token, Sim_{AST} means the similarity based on syntax. w_{txt} means the weight of similarity based on text, w_{Token} means the weight of similarity based on token, w_{AST} means the weight of similarity based on syntax .The following are the details of homology detection method based on AHP, and process to determine the weights of three algorithms.

Construct the AHP Hierarchical Model of Codes' Comprehensive Similarity

AHP hieratical model includes Target layer, Criterion layer and Scheme layer[8][9].

It explodes analyzed object to establish the whole evaluation index system. In AHP hieratical model, the aim will analyzed object achieved in Target layer, the medium environment which was need to reach the final goal is in Criterion layer, The actual method should be objectively choose is in Scheme layer.

Integrate the similarity measurement method based on text, token and syntax, this paper proposed an improved similarity measurement model based on AHP. In it, the design of comprehensive similarity is in target layer; miss rate and false detection rate belong to criterion layer as design; alignment methods in scheme layer.

The proportion of similar code in all is similarity of software's source code. Because of the limitation of different method used to calculate codes' similarity, also because of there so many types of plagiarism, miss detection and false detection are unable to avoid. Hence we use those factors having a quantitative evaluation.

Error detection rate is the rate of codes aren't similarity are detected as the similar code, miss rate is the ratio of similar code has not been detected. They have different influence in comprehensive similarity. As software source code homology detection technique is mainly used to find the similarity code, miss detection rate is comparatively more important. Through sufficient statics of lab data and experts' experiences, we set the ratio of miss detection rate and false detection rate 4:1.

Table1 compare text, token and syntax detection ways' result of different plagiarism type, result shows the plagiarism can be detected by previous method can also be found out using the latter. That is to say, if text based method can find some types of plagiarism, they can also be found using token based method, in a similar way between token and syntax. In other words, only using abstract syntax tree, there are no miss detections. Therefore the ratio of their contribution to miss detection is close to 0:0:1.

Table 1 Analysis of the Contributions of Text, Token and Syntax based Comparison Method

Sequence Number	Plagiarism Type	Text (1)	Token (4)	Syntax Tree (8)
1	Full-text copy	Y	Y	Y
2	Change variables 'name	N	Y	Y
3	Change parameters' name	N	Y	Y
4	Change the order of parameters	N	N	Y
5	Change the order of variables	N	N	Y
6	Change the method's name	N	Y	Y
7	Change the type of variables	N	N	Y
8	Add useless variable	N	N	Y
9	Reconstitute code	N	N	N

Table 2 shows the comparison of text, token, syntax in types of false detection, in the table, text doesn't have the general three types false detection, token will have false detection face to two situations and abstract syntax tree only have false detection in one situation. Therefore, in this paper the ratio of contributions of false detection rate in text , token, syntax is 3:1:2.

Table 2 Factor analysis of text, token, syntax' contribution of false detection rate

False Detection Methods	Text (3)	Token (1)	Syntax Tree (2)
Short Expression False Detection	Y	N	Y
Short Statement Block False Detection	Y	N	Y
Hash conflict False Detection	Y	Y	N

Through analysis we got the modified homology detections measuring algorithmic model (figure1) based on AHP. Destination Layer is the comprehensive similarity; criteria layer is the measurement index of miss and false detection; solution layer is the text, token, abstract syntax tree alignment methods. Only the results of abstract syntax tree comparison contribute to the miss detection as text comparison and Token comparison contribute 0.

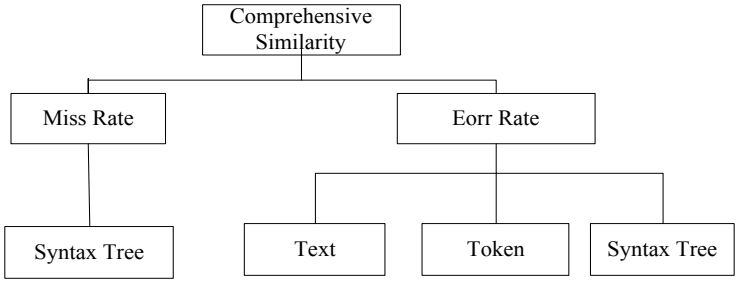

Figure 1 Improved homology detection hierarchical model

In order to use the modified homology detections measuring algorithms, it is needed to use AHP hierarchical model to do the counting on the weights of similarity of different alignment methods in the solution layer. Apply the model of figure1 into hierarchy calculation model based on AHP in figure2 to enable to use the AHP model to do calculation.

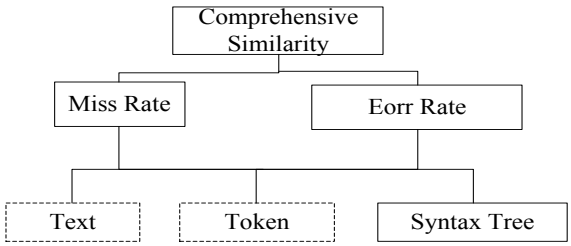

Figure 2 Improved homology detection model based on AHP hierarchical model

The structure of two contribution judgment matrixes between two layers

According to Table1, since the text and token comparisons contribute nothing to the miss detection, it is not necessary to count the judgment matrix. In terms of the miss detection rate(B1), the ration of the weights of text, token, syntax can be set to 0:0:1.According to Table2, when getting the judgment matrix for false detection, based on the 3 homology alignment algorithms based on text, token, syntax tree, the matrix for false detection is shown in Table3.According to sufficient statics of lab data and experts' experiences, contribution judgment matrix of miss detection rate(B1), false detection rate(B2) is shown in table 4.

Table 3 Contribution judgment matrix of text, token and syntax tree,

B2	C1	C2	C3
C1	1	3	2
C2	1/3	1	1/2
C3	1/2	2	1

Table 4 Contribution judgment matrix of miss and false detection rate

A	B1	B2
B1	1	4
B2	1/4	1

After consistency check[11], C.R. of the above two matrices are 0.0176 and 0, conform to the condition of consistency check, therefore, the above two judgment matrix through the consistency check is reasonable.

According to the process of single hierarchical ordering[11], doing the single ordering of above judgment matrix, get the single ordering weight of every layer:

B2	Weight of single ordering
C1	0.54
C2	0.16
C3	0.3

A	Weight of single ordering
B1	0.8
B2	0.2

For miss detection rate, analyzing above result and get the hierarchical single ordering weight as following table:

B1	Weight of single ordering
C1	0
C2	0
C3	1

Through above sorting process, we get the overall ranking levels：

A	0.8	0.2	Weight of Overall Sorting
C1	0	0.54	0.108
C2	0	0.16	0.032
C3	1	0.3	0.86

According to weight of overall sorting, the alignment algorithm based on text, token, syntax, their weight in comprehensive similarity respectively are 0.108,0.032,0.86.

Therefore, according to (1) we can the comprehensive measurement model of source codes' similarity is:

$$\text{Sim} = 0.108Sim_{txt} + 0.032Sim_{Token} + 0.86Sim_{AST} \qquad (2)$$

The results and analysis of experiment

In order to test the effect of model Based on improved AHP comprehensive similarity measure homology, in this paper, we had done two kinds of experiments. One is to detect specially constructed plagiarism of Hibernate source code, and the other is to detect real open source code projects.

The results and analysis of detection experiment on specially constructed plagiarism of Hibernate source code

In order to construct experimental test sample ,we will let Hibernate source apply copy the code snippet, displacement of the member variable names, displacement of method names ,upset the order of parameter, upset the order of the member variables and other analog plagiarism. And this test sample contains a comparison against the Token and abstract syntax tree structure than on a variety of error detection code snippets. Through artificial plagiarism and expert judgment, Hibernate test samples Hibernate and source code with Hibernate have real similarity with 75.1%.

Table 5 Result of specially constructed plagiarism of Hibernate source

Test sample	Similarity of text	Similarity of token	Similarity of syntax	Similarity in real	Improved comprehensive similarity
Hibernate source	51.4%	85.2%	76.8%	75.1%	74.3%

In connection with the above experimental test samples, Text-based, Token-based and Syntax tree-based detection results respectively are 51.4%, 85.2% and 76.8%. According to three results calculation formula(2) to calculate the comprehensive similarity was 74.3%, compared with the detection results of three single detection method, this paper puts forward the improvement of the homology of comprehensive similarity calculation model based on AHP test results, closer to the real similarity.

Comprehensive similarity detection result and analysis of open source code projects

For comparing with the comprehensive similarity detection model proposed in reference [11], using the source code of Snort-2.9.0.4, 7zip-9.22, Freemind-0.9.0, Notepad++-5.9, Filezilla_Client-3.5.0, WinMerge-2.12.4 and other five soft wares , combine with ten plagiarism ways to have the measurement under our homology detection model(the improved comprehensive similarity measurement based on AHP). The result is shown in table 6.Formula of comprehensive error:

Comprehensive Error = (Comprehensive Similarity –Real Similarity)/Real Similarity (3)

Table 6 Comprehensive similarity detection result of open source code projects

Test sample	Text (%)	Token (%)	Syntax (%)	Real (%)	Before improvement[11] (%)	After improvement (%)	Error rate before improvement [11] (%)	Error rate after improvement (%)
Snort-2.9.0.4	51.6	82.3	80.1	77.6	76.1	77.1	1.9	0.6
7zip-9.22	32.8	59.2	53.1	50.8	51.5	51.1	1.4	0.6
Freemind-0.9.0	61.6	91.5	89.3	86.9	85.6	86.4	1.5	0.6
Notepad++-5.9	35.7	56.1	52.7	51.7	50.9	51.0	1.5	1.3
WinMerge-2.12.4	52.4	83.6	79.8	77.5	76.4	77.0	1.4	0.6
aMule-2.3.1rc1	64.3	92.3	90.8	88.5	87.0	88.0	1.7	0.6
Pidgin-2.8.0	21.5	53.1	52.8	50.2	47.9	49.4	4.6	1.6
Wine-1.1.23	42.6	72.8	69.3	67.6	66.0	66.5	2.4	1.6
MPlayer-1.0rc4	57.6	85.5	81.6	79.1	78.8	79.1	0.4	0
All the code	42.3	71.9	68.7	65.8	65.3	66.0	0.7	0.3

Experiment result shows that the improved comprehensive similarity measurement model based on AHP is more close to the real value compare with the way only based on text, token and abstract syntax tree. Comparing with the way in reference [11], our way has lower error rate. Therefore our model is more accuracy.

Conclusion

In this paper, we propose an improved comprehensive similarity measurement model based on AHP, it considers miss detection rate and false detection rate as the indexes. By the way, we also propose a different analysis method of contribution of miss detection rate of the three comparison algorithms. Experiment result shows that compare to other algorithm, the improved homology detection system has higher accuracy rate.

Keywords: Continuous function, Mean Evolutionary algorithm, Variation operation, Selection operation

Abstract. A new Evolutionary algorithm was presented based on intermediate value theorem of continuous function. The global search ability and the local search ability of this algorithm are well balanced, and operators used in the algorithm are simple, Further, small size of population scale is used. Initial numerical experiments show that the mean evolutionary algorithm is better than differential evolution algorithm in solving high dimension function optimization.

Introduction

Continuous function is fairly broad class of functions. Intelligent algorithms suitable for continuous function include Genetic Algorithm (GA)[1], Particle Swarm Optimization (PSO)[2], Differential Evolution (DE)[3] and the various improved algorithms. GA lays the basic ideas of evolutionary algorithm, which are heredity and variation. The so-called heredity is to retain the superiority of the previous generation, while random variation provides an opportunity to open choice. Some specific operations of genetic algorithm are constantly being improved, such as binary encoding and cross, etc. PSO makes the algorithm more efficient for optimum individual chooses better individual. DE algorithm divides the algorithm into early stage and late stage. The early stage coordinates with global search, and the late stage coordinates with local search, which enables the algorithm to not easily fall into local optimum and have faster convergence. As for algorithms addressing certain problems, in order to be efficient, it has to consider some of the basic characteristics of such problems. The intrinsic property of continuous functions is its intermediate value. Mean Evolutionary Algorithm (ME) is proposed on the basis of the intermediate value of continuous functions, and absorbs some ideas of Differential Evolution Algorithm.

Mean Evolutionary Algorithm

1 Algorithm ideas

It can be found from the properties of continuous functions that: In the line segment linking large function value point and small function value point, there must be a number of points, the function values of which are equal to the mean value of two endpoint functions. They are referred to as the equilibrium point. The operation seeking equilibrium point is called equalization. Within several given points, use the equilibrium point to substitute the large function value points, then a group of small function value points can be obtained; use equilibrium point to substitute the small function value points, then a group of large function value points can be obtained. For two given function points with unequal values, you can choose the small function value point as the equilibrium point, and use the large function value point to get another small function value point; If using large function value points as the equilibrium point, the small points can thus promote the large function value points. According to this a group of more excellent [1]points can be obtained. Starting from the equilibrium point and the given point to find the operation of another point is referred to as

anti-equilibrium. In order to make the algorithm have faster convergence, the mean algorithm learns from the crossover operation of differential evolutionary. Through equilibrium, anti-equilibrium, crossover and selection, it ultimately finds the global optimum point.

2 Algorithm major operations

The following specifically gives an equilibrium and anti- equilibrium computing expression according to weighted average, and then gives the major operation of mean algorithm of D-dimensional objective function based on the population size of NP.

Consider the optimization problem:

$$\text{Min } f(x), f: R^D \to R \ , \tag{1}$$

Whose objective function $f(x)$ is continuous in its defined area? If the line segment AB is located in the region, and $f(A) < f(B)$, Then in the line segment AB there exists at least one point P so that $f(P) = \frac{f(A)+f(B)}{2}$. At this time P is the equilibrium point of function $f(x)$ in the line segment AB. Set A point's corresponding vector x_A, B point's corresponding vector x_B, P point's corresponding vector x_P, then x_P can be calculated as follows:

$$x_P = \lambda x_A + (1-\lambda)x_B = x_A + (1-\lambda)(x_B - x_A), \ \lambda \in (0,1) \tag{2}$$

In turn assume A is an equilibrium point linking B and Q， then $x_{\mathrm{A}} = \lambda x_{\mathrm{Q}} + (1-\lambda)x_B$， and then

$$x_{\mathrm{Q}} = x_A - \frac{1-\lambda}{\lambda}(x_B - x_A) \tag{3}$$

Compare the computational formula (1) and (2), both can be summarized as a formula

$$x_A + \mathrm{F} \cdot (x_B - x_A) \tag{4}$$

But when as an equilibrium calculation, $0 < F < 1$； as an anti-equilibrium calculation, $F < 0$.

(a) Variation Operation

Use the current point $x_{i,G}$ and another randomly selected point from the current population $x_{j,G}$ to produce a new point according to the above-mentioned equilibrium or anti- equilibrium operation, recorded as $v_{i,G+1}$, namely

$$v_{i,G+1} = x_{i,G} + F \cdot (x_{j,G} - x_{i,G}), \quad F = \begin{cases} \frac{1}{3} & if(rand \le 0.5) \\ -1 & otherwise \end{cases} \tag{5}$$

rand is a uniformly distributed random number in the interval [0,1].

(b) Crossover Operation

By hybridizing the point $v_{i,G+1}$ generated from variation operation and another randomly selected point from the current population $x_{k,G}$, the candidate points $u_{i,G+1} = (u_{1i,G+1}, u_{2i,G+1}, \cdots, u_{Di,G+1})$ are produced, namely

$$u_{jt,G+1} = \begin{cases} x_{jk,G}, if(j \in S) \\ v_{ji,G,} otherwise \end{cases} \tag{6}$$

S is a non-empty random subset, and the order of the subset does not exceed $\mathrm{D}/2$.

(c) Selection Operation

Select the function value of the comparison point $u_{i,G+1}$ and the point $x_{i,G}$, select the optimum function value point to enter the next generation population, i.e.

$$x_{i,G+1} = \begin{cases} u_{i,G+1} & if(f(u_{i,G+1}) < f(x_{i,G})) \\ x_{i,G} & \text{otherwise} \end{cases} \tag{7}$$

3 Algorithm Procedures

(a) The generation of the initial population

Randomly generate n points as the initial population, and calculate the function value of each point.

(b) Two ways to generate new points

The first way is to randomly select two different points from the given n points. Set $\lambda = 1/2$, In other words, use $F = 1/3$ for equilibrium operation to compute a new point. The reason for choosing $\lambda = 2/3$, rather than $\lambda = 1/2$ to calculate the equilibrium points is that the calculated equilibrium points from A to B will not repeat with the calculated equilibrium points from B to A, in order to better improve the operation efficiency. The second way is to randomly select two different points from the given n points. Set $\lambda = 1/2$, In other words, use $F = -1$ for anti- equilibrium operation to compute a new point. Through equilibrium or anti-equilibrium operation, for the given n points, each point (parent) will generate a different new point. Whether the way of generating new points is based on equilibrium way or anti-equilibrium way is determined by the probability 0.5. Afterwards, the new points carry out a crossover operation with points other than parent, and then compare the parent with the function values of new points after cross-point. Select excellent points to enter into the next generation.

(c) Generate new population

Based on the n points generated from Step (b), a new population is constituted. It is apparent that the new population is better than the previous generation. As per algorithm termination conditions, the population is tested to verify whether it meets the requirements. If it meets the requirements, output the results and comes to an end. If it fails, it does not meet the requirements, and then goes back to Step (b).

4 Algorithm Analyses

Mean evolutionary algorithm has strong global search ability and local search ability. Generally the required initial population is small, the operator is simple, and the programming is brief. Since the points generated from equilibrium are located within the current population, which are close, the algorithm local search ability becomes stronger. In terms of the points arising from the anti-equilibrium operation, they are distant in relative to the current population, and these points are widely distributed. Therefore, the algorithm global search ability becomes stronger. In addition, the characteristics of the excellent points are retained through cross-over. Mean evolutionary algorithm has simplified the operation of differential evolutionary algorithm cross-over, which improves the convergence speed. In order to prevent premature convergence, the cross-over location number of the mean evolutionary algorithm is no more than half the number of dimensions.

Mean evolutionary algorithm simulation

1 Test Functions

In order to test the performance of the mean evolutionary algorithm, several important test functions have been selected from the literature[4][5] for testing, they are:

$$f_1(x) = \sum_{i}^{k} x_i^2, x = (x_1, x_2, \cdots, x_k), \quad -100 \le x_i \le 100, \ k = 30 \ \text{(Sphere function)} \tag{8}$$

$$f_2(x) = \sum_{i=1}^{k-1} [100(x_{i+1} - x_i^2)^2 + (x_i - 1)^2], \quad -30 < x_i < 30, k = 30 \ \text{(Rosenbrock function)} \tag{9}$$

$$f_3(x) = 10k + \sum_{i=1}^{k} [x_i^2 - 10\cos(2\pi x_i)], \quad -5.12 \le x_i \le 5.12, k = 30 \ \text{(Rastrigin function)} \tag{10}$$

$$f_4(x) = \frac{1}{4000}\sum_{i=1}^{k} x_i^2 - \prod_{i=1}^{k} \cos\left(\frac{x_i}{\sqrt{i}}\right) + 1, \quad -600 \le x_i \le 600, k = 30 \ \text{(Griewank function)} \tag{11}$$

2 Test Results

Table 1 shows the experimental data of each tested function obtained via ME algorithm and DE algorithm on the condition that the population size and the number of iterations stay unchanged. Table 2 shows the outcomes of the tested function acquired using ME algorithm and DE algorithm respectively under different dimensions.

Table 1 Simulation results using ME algorithm and DE algorithm (20 experiments)

Test function	The known optimal value	ME algorithm		DE algorithm		Population size	Iterations	t-test
		The best optimal value	Mean optimal value	The best optimal value	Mean optimal value

f_4	M	6.0e-06	7.0e-02	1.5e-01	4.2e-01	8.5e-01	1.43633	1.48415	1.77850	4.43995	3.58719	0.001
	D	3.70248	3.73610	3.67226	3.65457	3.66152	3.66627	3.67147	3.64041	3.66908	3.66488	

The statistical tests in the table 1 and table 2 is accomplished by R software. The tests in table 1 belong to two-side t-test for independent group means, and the tests in table 2 belong to matched pairs two-side t-test between means. Figure 1 is the scatter diagram after 50 iterations in order to describe the ME algorithm evolutionary process for f_4, when $k=2$, the initial population size is 30; The scatter diagram denoted Figure 2 describes the DE algorithm evolutionary process for the same objective function and the same iterative condition as Figure 1. The variation curves in Figure 3 show the evolutionary process of the optimal values for the same experiments as Figure1 and Figure 2 respectively. The both curves in Figures 4 are respectively the change trend charts of function f_3's optimal value after 600 iterations using the ME and DE algorithms, when $k=30$, the population size is 60. In the test the DE algorithm is always set as $F=0.8,\ CR=0.3$.

3 Analysis of test results

It can be seen from the test results that, with the increase in the number of test functions dimension, ME algorithm is apparently superior to DE algorithm, $p \leq 0.002$ (see Table 2); for low-dimensional function, DE algorithm demonstrated high accuracy and good stability. Compared with ME algorithm, its volatility is greater. However, in many experiments, the accuracy of optimal values

calculated by ME algorithm is better than that of DE algorithm (see Table 1). In addition, the stability of DE algorithm also exposed the weaknesses of premature convergence (see Figure 4).

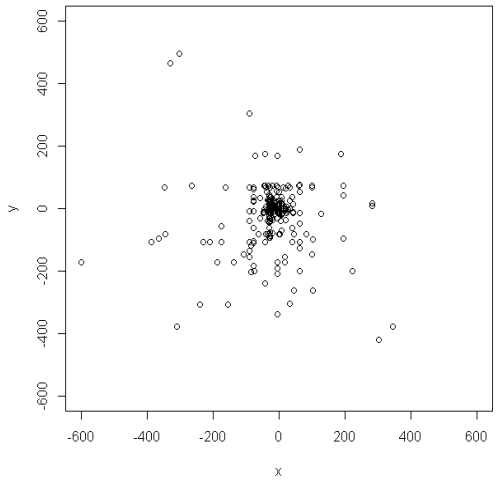

Fig.1. The evolution scatter diagram of f_4 with k=2 by ME

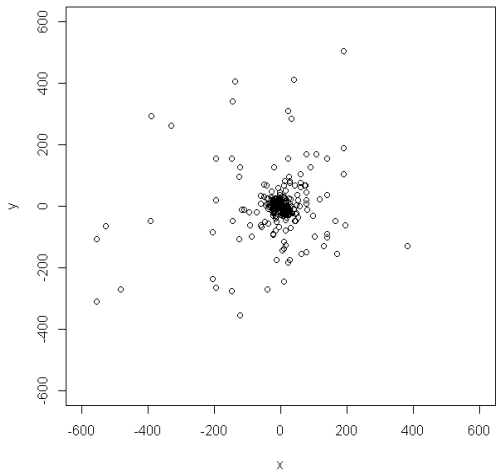

Fig.2. The evolution scatter diagram of f_4 with k=2 by DE

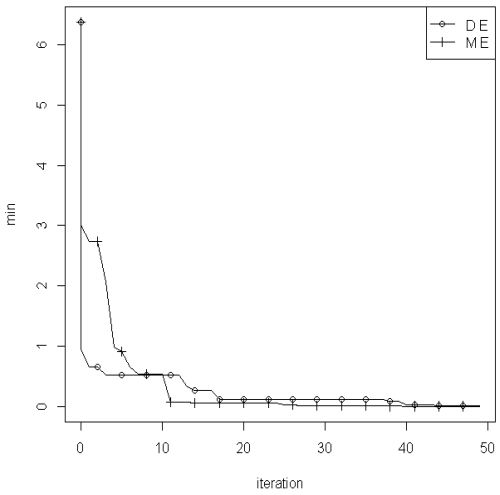

Fig.3. The evolution curves of f_4 with k=2 by ME and DE

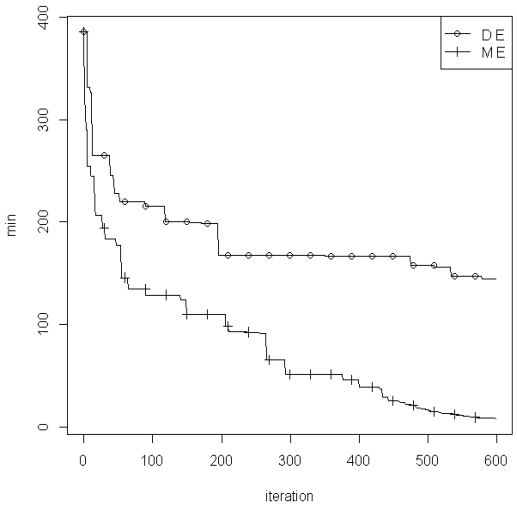

Fig.4. The evolution curves of f_3 with k=30 by ME and DE

The difference between ME algorithm and DE algorithm testing results is mainly the difference in mutation operator. Operator (11) and (12):

$$v_{i,G+1} = x_{i,G} + F \cdot (x_{j,G} - x_{i,G}) \tag{12}$$

$$v_{i,G+1} = x_{r1,G} + F \cdot (x_{r2,G} - x_{r3,G}) \tag{13}$$

Seemingly the forms are very similar, but their functions are very different. Operator (5) in ME algorithm contains more $x_{i,G}$ elements, which enables the progeny to retain more personalized elements, while operator (6) in DE algorithm contains no $x_{i,G}$ elements. Even if the following cross effect contains $x_{i,G}$ elements, the personality characteristics of its progeny have been greatly weakened, so that the next generation of individuals can easily have convergence, which directly leads to the weakness of premature convergence of DE algorithm.

For the high precision of DE algorithm in treating low-dimensional functions, it mainly depends on the diversity of operator (12) values, including DE/rand/2/bin strategy in DE algorithm, which uses the characteristic of rapidly increasing combinations C_n^3, C_n^4 with the increase of n. Simply relying on a great number of points to search for the optimal value may not be efficient. Mutation operator in ME algorithm is proposed basing on the intermediate value of continuous functions, so that the desired points have a good directivity, and thus have more efficiency.

Conclusions

In terms of mean evolutionary algorithm, although it has some characteristics of some other algorithms, it has its own ideological origins, which can be traced back to the Yin-Yang idea, and "Tai ji Diagram". ME algorithm involves equilibrium and anti-equilibrium operations, and the meaning of the equilibrium point is extremely rich. There are equilibrium and anti-equilibrium operations based on the different understandings of the equilibrium point, which can lead to more algorithms that will not only be suitable for continuous functions, but also be suitable for more and broader issues such as portfolio optimization. All of these will be the direction of future research.

Keywords: Decision tree; classification; Meta-analysis; Visual data mining

Abstract. In the social sciences, meta-analysis has been used on a limited scale only, mainly because there still remains a gap between the knowledge available and itsapplication in policymaking. The experimental results suggested that, compared to the automatic modeling process as typically applied in current decision tree modeling tools, interactive visual decision tree (IVDT) process can improve the effectiveness of modeling in terms of producing trees with relatively high classification accuracies and small sizes, enhance users' understanding of the algorithm, and give them greater satisfaction with the task.

Introduction

In many cases, it is not to be regretted if publications are forgotten because their relevance has faded away. There are a lot of publications that should have an impact for a much longer period than they have nowadays, however. Now we are talking about books and articles that get lost in the quickly growing stream of publications. As an illustration of the size of the problem we take the thirty million books and eighty million articles and brochures stored in the Library of Congress in Washington.Sophisticated data analysis mining methodology is required to curb non-utilization in data sets of this kind. Visual data mining (VDM) has become an active research area. VDM can be viewed as an integration of visualization and traditional DM techniques, such as visualizing raw data to help users discovering data characteristics, visualizing models obtained from DM to enhance understanding of the derived patterns, and visualizing DM process during which models are induced.

Many researchers have argued that visualization can be integrated withnonvisual techniquesto greatly enhancethe effectiveness and efficiency of a DM process[1]. The accuracy of a model is only one measure that can be used to value its worth. The ability to interpret the model to domain experts and decision makers and the ease of implementation and maintenance are other important factors. [2] stated that without proper visualization techniques, DM models, although a reduced form of original data, may not give the desired insight to help humans understand the phenomena of interest.

Meta-analysis

According to Lipsey and Wilson,there are basically three reasons for using meta-analysis to analyse and summarize a body of research studies rather than applying conventiona lresearch reviewing techniques[5].

First, meta-analysis procedures enhance the discipline in summarizing research findings. Also, meta-analysis requires that each step be documented and open to scrutiny.Furthermore,it leads to specification of the criteria that define thep opulation of study findings to be analysed.It requires search strategies that assist to identify and retrieveeligible studies,for malcoding of study characteristics andfindings.Finally, it also requires data analysis to support the conclusions that are drawn [3].

Second, meta-analysis represents study findings in a more differentiated and sophisticated way than conventional review procedures that only supply qualitative summaries.'By encoding the magnitude and direction of each relevant statistical relationship in a collection of studies, meta-analysis effect sizes constitute a variable sensitive to different strengths across studies' [3].

Third, meta-analysis is capable of finding effects or relationships that are not made explicit in other approaches to summarizing research.Meaningful effects and relationships upon which studies agree,and differentiated effects related to study differences, are more likely to be discovered by meta-analysis than by less systematic and analytic approaches [3].

Proposed conceptual model of visualization support to data mining modeling process

DM modeling consists of three main tasks: algorithm selection, model construction, and model evaluation. First,appropriate DM algorithms need to be selected, depending on the DM problems to be addressed. The key decision during model construction is to choose an appropriate set of parameters for the selected DM algorithm to fit the prepared data set. Because the parameters are not known apriori, however, model construction is recursive and can be very time-consuming. After a model is derived, it needs to be assessed by evaluating its performance, interpretability,and/or other measures, according to the corresponding DM tasks. Based on the evaluation outcomes and predefined DM goals, the induced model may have to be refined by choosing a different set of parameters or even a different algorithm.Data visualization, such as visualization of distributions of data attributes and dependencies among data attributes, assists users in discovering and understanding relationships within data; it leads to the creation or enhancement of a mental model that captures the implications of the data relative to the modeling objective [4], and thus can facilitate selecting appropriate DM algorithms and their parameters.

Visualization of model-building process, such as presenting parameters and model update, serves to not only help users understand how a model is derived, but also provide them thediscernment todirect model construction,adjusting the parameters based on their background knowledge and pattern recognition capacities as situations warrant. Studies in [5] showed that an important characteristic of experienced modelers, in contrast to the no viceones,was their continual self-monitoring of progress; they often suspended an activity at one stage and returned to an earlier stage. Visualization of models is the presentation of the obtained results or knowledge in visual forms. Its purpose is to enable users to quickly identify the important features of the derived patterns, such as the number of nodes and relationships among nodes in an induced decision tree.

Integration of scientific knowledge into social impact assesment

If the campaign against non-utilization of knowledge would be restricted to meta-analysis and value transfer,the outcomes of the campaign would be too limited.We have to hunt down non-utilizers not only among scientists but also among consultants, decision-makers and members of the public in general. Let us start with a close look at each of the four social roles involved.

Extended meta-analyses in research programs

The role of extended meta-analyses in integrated research programs will increase, because these programs will more and more have access to substantial databases relevant for their research questions. In these situations, ‘can implies ought’. It would be inefficient not to use these databases.

In these research programs, extended meta-analyses will be applied at the beginning, during and at the end of the program. If applied research is involved, impact assessment will not always be required.

Research programs have to become more transparent and more accountable, because of the requirements of financing agents. This applies in particular to research financed out of the taxpayer'smoney. Governments have to organize an open tendering for the projects that constitute the research program. As an example, we will discuss now a research program launched by a national science foundation that will have to contribute to policy-oriented and discipline-oriented knowledge.The national science foundation will be able to finance four projects and it is confronted with forty reactions to its tender.It is evident that a multi criteria analys is will have to be applied for evaluating and ranking the forty potential projects.

Experiment

An experiment was administered to test three hypotheses regarding the proposed IVDT by comparing it with the automatic approaches applied in current decision tree softwares. Although decision tree is one of the most popular so called ‘‘supervised’’ learning tools, the present decision tree softwares allow very limited forms of guidance from users.

In consequence, the common approach is to run the algorithm with parameters set at their default values, hoping to discover some interesting patterns, or build several trees with different parameters settings, compare their results, and choose the one that is the best. Such an approach forces the user to blindly explore a huge parameter space without clues and intuition about which parameters could give better results. In contrast, the proposed IVDT enables the involvement of the user to guide tree construction by providing them the insight to check the intermediary outcomes and select appropriate parameters.

Conclusions and future research

We have been able to show, that in many cases adequate databases are already available and that they are further improved. We have also been able to demonstrate that for each of the components sophisticated methodology is available. The loosely coupled relationships between visualization and analytical DM techniques represent the majority of the current state of art in visual DM; DM modeling is typically an automatic process with very limited forms of guidance from users. A conceptual model of the visualization support to DM modeling process and a novel IVDT classification process have been proposed in this paper, with the aim of exploring humans’ pattern recognition ability and domain knowledge to facilitate the knowledge discovery process. An experiment was administered to test three hypotheses regarding the potential merits of the proposed IVDT process, whose results suggested that compared to the automatic modeling process, IVDT process can improve the effectiveness of modeling, enhance users’ understanding of the algorithm, and give them greater satisfaction with the task.

Keywords: OFDM-PON, training sequence, symbol synchronization

Abstract. A new structure of short training sequence for symbol synchronization in OFDM-PON system is proposed in this paper. By adjusting the subcarrier allocation scheme of short training sequence in a wireless LAN, it makes the mean of short training sequence signal in time domain from non-zero to zero mean and solves the receiving data demodulation interference caused by the wrong trail of the non-zero mean short training sequence in time-domain. Data demodulation simulation and experimental results show that the improved method can effectively reduce the training sequence interference errors caused by tailing.

Introduction

Orthogonal frequency division multiplexing passive optical network (OFMD-PON) is regarded as a potential technique to be applied in next generation passive optical network (NG-PON). Combination of OFMD and PON can make the most of spectrum resource. OFDM can achieve QPSK, 8PSK, 16QAM and even higher order modulation in each subcarrier by mapping signal to constellation. In TDMA and OOFDMA network, several users share bandwidth. This makes challenges to exact symbol synchronization because symbol synchronization and aligning slot time of each ONU signals must be finished in real time. OFDM-PON system is sensitive to synchronization, which is a major defect. Synchronization is one of the most significant works of OFDM receiver.

At present, there are many papers that propose quite a few algorithms about the synchronization of OFDM system in wireless LAN. These algorithms can be divided into two categories: algorithms based on non-data-aided such as algorithms based on cyclic prefix (CP)[1] and algorithms based on data-aided. The latter algorithms introduce short and long training sequence. By studying more efficient structure and code pattern of pilot and training sequence, receiver can extract synchronization information more easily. These algorithms feature low algorithm complexity and efficiency synchronization performance. Classen proposed this kind of algorithm early. His algorithm uses pilots in OFDM symbols to finish coarse synchronization and fine synchronization. Since the coarse synchronization should blindly search in a certain range, this algorithm costs too much calculation. Then Schmidl improved Classen's algorithm by added two same blocks with N/2 length in the header of each data frame. Receiver can search the peak and find the starting position of data frame through delay correlation algorithm. However, this algorithm has low precision cause of the plateau[2]. Shi and Serpedin added four same training sequences in the head of data frame and the third is inversed. This algorithm can improve the precision but still can't make it satisfied[3][4]. Bo-Seok improved Schmild's method in his paper. Two OFDM symbols are used as training symbols in Bo-Seok's algorithm. It is different from Schmild's that every OFDM symbols are applied with differential phase shift keying (DPSK).This algorithm reduces calculation a lot and has almost the same performance[5]. The synchronization method used in optical experiment now comes from wireless LAN. Since the limit of optical channel, low subcarriers have serious distortion. This paper proposes a new structure of short training sequence applied to OFDM-PON system, which reduce the distortion of low subcarriers.

Synchronization Theory in OFDM System

There has been a similar allocation scheme of short training sequence in wireless OFDM system. This scheme shows well performance on symbol synchronization by using group detection. This scheme is shown on Fig.1 and the number of used subcarriers in short sequence is underlined.

Fig.1 Carrier distribution map and load the data table

It is different from wireless that OFDM baseband signal should be real in baseband direct modulation optical transmission. This problem can be solved through Hermite complex conjugation. The prior 32 subcarriers of OFDM signal are conjugated with the latter 32 subcarriers. This kind of OFDM signal can be transformed to real signal after IFFT. However, this change on structure will introduce a new problem. At the starting position of OFDM symbol in receiver, relatively large error is observed after FFT and points on received constellation deviate from standard points. It is analyzed that this phenomenon is caused by unreasonable allocation of short training sequence. The mean of short training signal in time domain is not zero, which will cause wrong trail in optical transmission and interference to low subcarriers. This paper proposes a new allocation scheme of short training sequence suitable for OFDM-PON system to solve this problem effectively.

Modified Allocation Scheme of Short Training

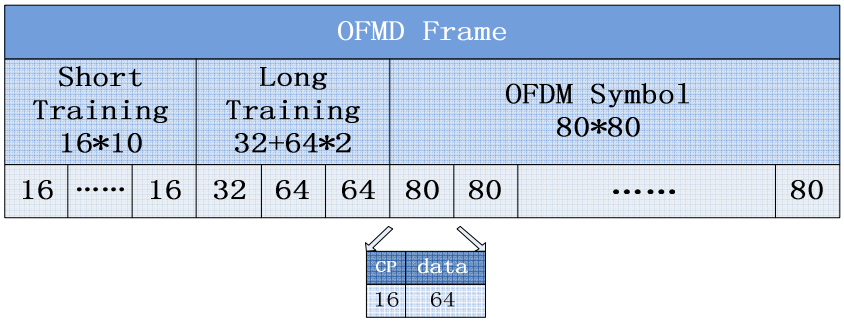

Fig.2 Frame structure diagram of the OFDM signal

The frame structure of short training sequence is shown on Fig.2. 64 subcarriers are transformed to time domain signal after 64 points IFFT. We select a quarter of the time domain signal (16 points) out and repeat them 10 times. This is the generation of short training sequence with 160 points. The time domain expression of short training sequence is shown as

$$t_{Ts}(\mathrm{t}) = \frac{1}{\mathrm{N}}\sum_{n=0}^{N-1} X_{n,m} e^{j2\pi\Phi_{n,m}t} \tag{1}$$

The frequency domain expression of prior 16 points is shown as

$$\mathrm{F}[t'_{Ts}(\mathrm{t})] = \sum_{n=0}^{N-1} T_{Ts}(\mathrm{n})\left(\frac{1}{5}T_s Sa\left(\frac{T_s}{10}(\omega - n\omega_{Ts})\right)\mathrm{e}^{j\frac{T_s}{10}(\omega - n\omega_{Ts})}\right. \tag{2}$$

The frequency domain expression of short training sequence is shown as

$$\mathrm{F}(t'_T(\mathrm{t})) = \mathrm{F}[t'_{Ts}(\mathrm{t})] + \mathrm{F}[t'_{Ts}(\mathrm{t})]e^{j\frac{1}{5}\mathrm{T}_s\omega} + \mathrm{F}[t'_{Ts}(\mathrm{t})]e^{j\frac{2}{5}\mathrm{T}_s\omega} + \cdots\cdots + \mathrm{F}[t'_{Ts}(\mathrm{t})]e^{j\frac{9}{5}\mathrm{T}_s\omega} \tag{3}$$

$$STS = \{0, 0, 0, 0, 1+j, 0, 0, 0,$$
$$-1-j, 0, 0, 0, \ 1+j, 0, 0, 0,$$
$$-1-j, 0, 0, 0, -1-j, 0, 0, 0,$$
$$1+j, \ 0, 0, 0, -1-j, 0, 0, 0\}$$

Fig.3 Schematic diagram of improved short training sequence subcarrier distribution

Fig.3 shows modified short training sequence subcarrier distribution and the number of used subcarriers is underlined. NO.1 and NO.30~36 subcarriers are null and used as guard band. The signal should be real since system uses optical intensity modulation. Therefore, 64 subcarriers are divided to two parts. The prior 32 subcarriers are conjugated with the latter 32 subcarriers. The time domain signal after IFFT is real. It is different from wireless that the used subcarriers loaded with short training are located at 4 times basic frequency. This change makes the mean of short training sequence signal in time domain from non-zero to zero mean. As shown in Fig.4, the frequency of NO.2 subcarrier is 1/Tc; the frequency of NO.3 subcarrier is 2/Tc; the frequency of NO.4 subcarrier is 3/Tc and so on. We select prior 16 points out and repeat them 10 times and generate 160 points short training sequence.

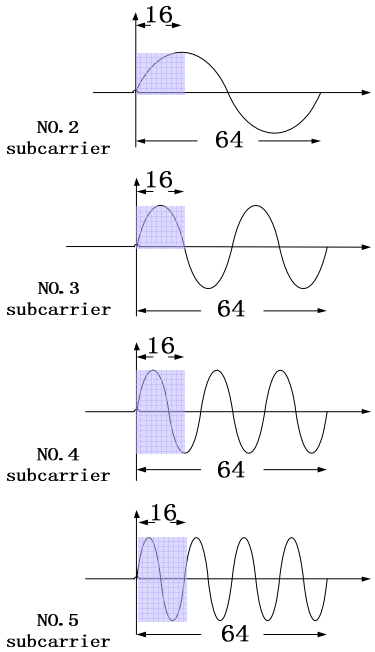

Fig.4 Schematic diagram of short training sequence in time domain

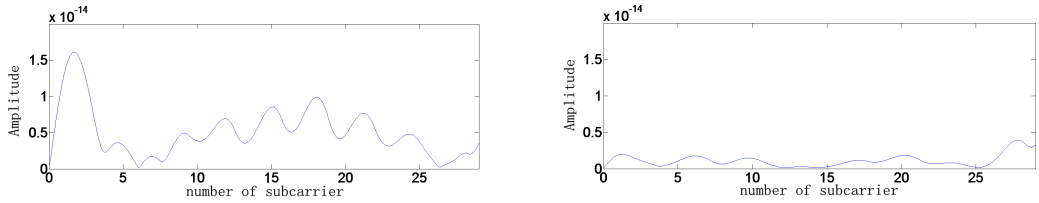
Since the prior 16 points are selected, only NO.5 subcarrier is zero mean in four subcarriers. Only 4 times basic frequency are zero mean in 64 subcarriers. This means only subcarriers at 4 times basic frequency will not interfere received data signal. The theory is as follow. The passing band of experimental system is 10MHz to 880MHz. The output of short training sequence after passing the channel is shown as

$$\mathrm{F}(t'_T(\mathrm{t}))\,\mathrm{H}(\omega) = \sum_{i=0}^{9} e^{j\frac{i}{5}\mathrm{T}_s\omega} \sum_{n=0}^{N-1} T_{Ts}(\mathrm{n})\left(\frac{1}{5}T_s Sa\left(\frac{T_s}{10}(\omega - n\omega_{Ts})\right)\mathrm{e}^{j\frac{T_s}{10}(\omega - n\omega_{Ts})}\right) \tag{4}$$

Since the interval of subcarriers is about 33MHz and NO.1 subcarrier is not loaded data, passing band can be treated as 0 to 880MHz. The points of first data symbol range from 339 to 400 and its time ranges from $337\mathrm{T}_0$ to $400\mathrm{T}_0$, where $\mathrm{T}_0=\mathrm{T}_S/80$ is sampling time. The expression of short training sequence for the 339 to 400 sampling points is shown as

$$\mathrm{s}(\omega) = \left(\sum_{i=0}^{9} e^{j\frac{i}{5}\mathrm{T}_s\omega}\left(\frac{1}{5}T_s Sa\left(\frac{T_s}{10}(\omega - n\omega_{Ts})\right)\mathrm{e}^{j\frac{T_s}{10}(\omega - n\omega_{Ts})}\right)\right) \otimes \left(\frac{4}{5}\mathrm{T}_s\, Sa\left(\frac{2T_s}{5}\omega\right)\mathrm{e}^{j\frac{2T_s}{5}\omega}\right) \tag{5}$$

Fig.5 is the theory analyzing results from formula (5). When transmitting null data, previous short training sequence will cause obvious interference to low subcarriers of data segment as shown in Fig.5 (a). This interference is reduced a lot after short training sequence improved as shown in Fig.5 (b).



(a) Before modified (b) After modified

Fig.5 Theory analyzing results

Experimental Results

The OFDM signal is generated in Matlab and transmitted by AWG. OFDM signal is modulated by DFB laser and received through 25km single mode fiber (SMF). Photovoltaic conversion is finished by PIN detector at receiver. The signal is sampled by OSC after passing an 880MHz LPF. The OFDM demodulation is also finished in Matlab.

The time domain waveform of experimental results is shown on Fig.6. All subcarriers in data segment are loaded zero. In real channel, low cut-off frequency is impossible to be zero and the 3dB cut-off frequency of experimental system is 10MHz. Therefore, there is wrong trail in non-zero mean training sequence. A sunk part can be observed in the waveform of previous short training sequence and it disappears after short training sequence is modified. The change is shown on Fig.6. Through making FFT of the two waveforms shown on Fig.6, we can analyze interference on every subcarrier. As shown in Fig.7, previous short training sequence makes more interference on the 3 prior subcarriers than modified. These experimental results agree with the previous theoretical analysis.

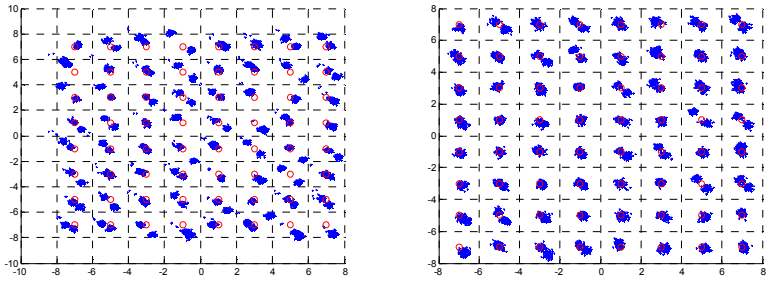
Fig.7 Carrier frequency spectrum of the improved receiver data segment

Fig.8 is the constellation of NO.2 subcarrier with 64QAM modulation. Before short training improved, data are demodulated with serious distortion. Before short training sequence improved, points are divided to two parts. This situation is improved a lot after the short training sequence is changed. Data can be recovered truly at receiver.



(a)Before modified (b) After modified

Fig.8 Constellations after loading the data

Conclusion

By adjusting allocation scheme of short training sequence in OFDM-PON system, transmission performance of experimental system is improved and the problem caused by unreasonable allocation of short training sequence in OFMD signal is solved. New allocation scheme of short training sequence makes marked improvement on system performance as shown in both theoretical analysis and experimental results. This modification can also be applied on Orthogonal frequency division Multiple Access for Passive Optical Networks (OFDMA-PON). According to the subcarrier occupied by each user, we can choose relevant training sequence based on four times frequency principle.

Three-Dimensional Yarns Modeling for Tufted Carpet Simulation

Li Jianghua[a], Chen Guangfeng[b], Huang Qingqing[c], Wei Xin[d]

Donghua University, Engineering Research Center of Advanced Textile Machinery, Ministry of Education, Shanghai 201620,China

Keywords: yarn modeling; fiber bundle; geometric modeling; tufted carpet simulation

Abstract. Yarns modeling are the key problem for tufted carpet 3D visual simulation. This paper deals with three-dimensional yarns structure modeling for tufted carpet simulation. The yarn is modeled as an assembly of fiber bundles which also include of a lot of fibers. to simulate fiber bundle dividing fiber bundle into many segments along its trajectory, and each fiber paths displayed are generated by NURBS curves. Through control the control points and color of NURBS to get certain cross-section and color effect of fiber bundle outlook. And finally use the fiber bundle to form the final yarn model. Test result shown the modeling method is suitable for carpet simulation.

Introduction

Basically, a yarn is composed of many fibers twisted to make up a yarn. Hence the solid structure of yarn should be constructed from fiber-structure parameters, such as fiber shape, fiber distribution, and the direction of the fiber twist [1]. Many researchers have developed models to display the visual characteristics of real yarns for modeling ply yarns structure, woven fabrics, knitted fabric and complex textile composite yarns. Most of the previous works regarding geometrical modeling of yarn structure are based on single line yarn path [2,3]. These presentations are limited to virtual representation and prediction of the micromechanical properties of yarn structure. Sriprateep and Bobez have developed a model of yarn as an assembly of many fibers by twisting.

For tufted carpet simulation, due to the limitation mentioned above, the yarn model could not be used for three dimension simulation of loop pile, a novel yarns structure modeling need to be considered.

Yarn Modeling Method

For tufted carpet, the yarn structure mainly has two types: interlacing yarn and twisting yarn [1]. General, a yarn is composed of many fibers bundles twisted to make up a yarn [4,5]. A general structure of yarn is shown as figure 1.

Several key factors affect the appearance of fiber bundles: centerline trajectory, fiber bundles of color, cross-section shape, and fiber bundle of twist. In this study, first construct fiber, composed by fiber of fiber bundles, again by fiber bundles of constructing yarn strategies. Use NURBS to express centerline bending posture, by scanning fiber entity, and assembly these fibers 3d model into 3d model of fiber bundles.Since the tufted carpet consists of tens of thousands of loop piles which formed by yarns, and each yarn consists of hundreds of fiber, fiber structure of the fiber bundles little impact on the carpet visual appearance, so fiber modeling adopts circle as the cross-section, through the control point controlling the fiber shape. Again by hundreds of fiber, and constitutes a fiber bundle for every fiber in increases in fiber bundles, make subsequent drift disturbance from the microscopic yarn modeling can also very approximate true yarns.

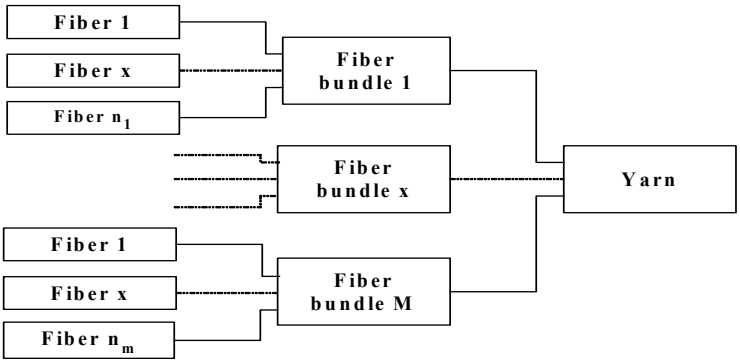

Fig. 1 Yarn composition structure diagram

Centerline trajectory description. NURBS curve: The fiber curve can be approximated by a curve called cubic NURBS curve, which is a parametric spline whose main components include the 2D or 3D control points. In addition, the weights of these points and a knot vector limit the effect of the control vertices onto a given segment of the curve. The fiber is defined as an open cubic B-spline curve with a constant radius of r described by the control points $\mathrm{q} \in R^{3m}$. In general, indices i, j range over spline segments, while indices k, l range over control points. The curve is described by Eq. 1 for a fiber with $N = m - 3$ spline segments, and where $b_k(s)$ is the cubic B-spline basis function associated with control point k. Through changing the actual value of control points, can actually control to the center of the fiber track. By dividing a fiber into section along the centerline of value, as long as it meets some requirements can fully infinite approximation actual fiber bundle center trends.

$$y(s) = \sum b_k(s)\mathrm{q}_k, s \in [0, N] \tag{1}$$

Color control of fiber bundle. For fiber in yarn always have different color, in order to simulate the effect of these color, we designate entity color while generating fibers, the fiber bundle with different color could be got. But for mixed colors fiber bundle, certain proportion separately for every fiber different color, achieve specified mixed color effect.

Cross section control. Cross-section shape of fiber bundle in the fabric are not constant, the key imitate fiber bundles of cross-section shape is to control every fiber in section regularity of distribution. In Common cross-section is in a circle, elliptic, runway form. Through the control points in every fiber in section, namely average distribution within the control can be guaranteed in the fiber bundle in cross-section shape.

The generation of random points for cross section control contains two main steps: the first step is to generate random points set in cross section. And then mapping the points set from local coordinate system to global coordinate system.

Construction of coordinate system. To generate the random point sets, we first construct the coordinate system of fiber bundle and the local coordinate system of cross section. The origin of local coordinate system is defined as the cross section center point, and (u_x, u_y) is in the cross section, u_z is perpendicular to the cross section.

Random data generation. There many kinds of cross sections. Using elliptical cross-section as a sample to generate the points set. Through the rand function as Eq. 2 to generate original random points (u_x, u_y).

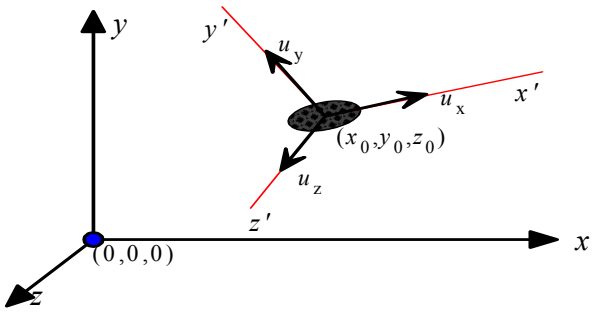

Fig. 2 Coordinate system for yarn cross section

$$\begin{cases} u_x = 2\times a\times \text{rand}(\,) - a \\ u_y = 2\times b\times \text{rand}(\,) - b \end{cases} \tag{2}$$

After the generation of the points, firstly get rid of the points outside the Elliptical, then calculate the distance between current points with valid candidate points and deleted the point if the minimize distance is smaller than the diameter of fiber.

$$f(u_x,u_y) = \sqrt{(u_x-u_{x1})^2+(u_y-u_{y1})^2} + \sqrt{(u_x-u_{x2})^2+(u_y-u_{y2})^2} \le L \tag{3}$$

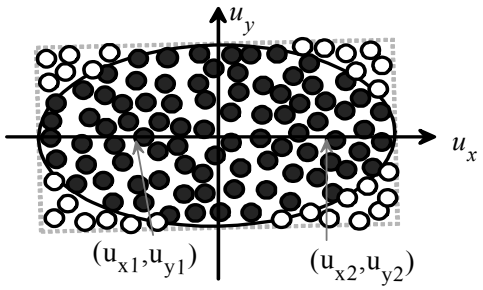

Fig. 3 Cross-section random data generation sample

For the process using pseudocode as follows to generate point set for cross section control.

$i = 0;\quad r = fibreDiameter;$
while$(i \le \text{MAX})\{$
$x = \text{rand}(); y = \text{rand}();$
if $(f(u_x,u_y) \le L)$ & $(\text{MinDistance}((u_x,u_y),(u_{xi},u_{yi})) \ge 2r)$
StoreInDataArrary (u_x,u_y);
$i++;\}$

Point mapping with the transform matrix. A point in space (x, y, z) transformations of any movement, rotation, scaling, can be accomplished through this point P_s multiplied by a matrix T *as* Eq. 4 to get the destination P_d, and get the destination point set.

$$T = R_x \cdot R_y \cdot R_z \cdot T_{xyz} \tag{4}$$

In Eq. 4 R_x , R_y and R_z are the rotation matrix as Eq.5 , and $\cdot T_{xyz}$ is the translation matrix as Eq.6. With the matrix we could get the destination point set. Base on the point set we could generate the curve to simulate the fiber bundle.

$$R_x = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos\alpha_x & \sin\alpha_x & 0 \\ 0 & -\sin\alpha_x & \cos\alpha_x & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} R_y = \begin{bmatrix} \cos\alpha_y & 0 & -\sin\alpha_y & 0 \\ 0 & 1 & 0 & 0 \\ \sin\alpha_y & 0 & \cos\alpha_y & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} R_z = \begin{bmatrix} \cos\alpha_z & \sin\alpha_z & 0 & 0 \\ -\sin\alpha_z & \cos\alpha_z & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{5}$$

$$T_{xyz} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ T_x & T_y & T_z & 1 \end{bmatrix} \tag{6}$$

Test and Discussion

We develop the program in VC++ together with Open Inventor to test the proposed method for yarn modeling. In the test process, we adopt B-Spline curve to represent the fiber in yarn. Yarn modeling process assumes all fiber is infinitely long, without considering short fiber structure on the yarn appearance influence.

Fig. 4 Fiber bundle with cross section control

Conclusion

This paper deals with the modeling method of yarn for tufted carpet simulation. The yarn is modeled as an assembly of many fibers. Each fiber paths displayed are generated by NURBS curves. Through control the fiber distribution in key points to control cross-section of fiber bundle. Test result shown the modeling method is suitable for carpet simulation

Keywords: emergency management; migrant group incident; Analytic Hierarchic Process (AHP); CBR; aid decision making

Abstract. This paper presents the findings of a study on decision making models for the migrant's worker group incident emergency management based on Analytic Hierarchic Process (AHP). Analytic Hierarchic Process (AHP) helps to quantitate and layer the complex migrant's worker incident emergency management problem, the aim of the work is to improve the support for analysis and decision through the importance comparing of various factors associated layer by layer.A case study conduct in Wukan village Shantou city of Guangdong province revealed that AHP model can do effective decision making

Introduction

Social relationship has been more complicated and hidden troubles and crisis have also been gradually revealed, especially the sudden group incidents had influence the step of government reform, social harmony and stability in the process of rapid urbanization in China because of inflation, structural reform, income distribution and other problems. Rural-urban continuum is the urban and rural joint areas which have the properties of land-use of both city and country. Triggered by some social contradictions, specific groups or no-specific people get together to establish occasional groups, in the form of contradictions among people with no legal basis, which causes negative impacts on society, even makes the language or physical conflicts, to express their demands and claims, strive for and maintain their own interests, let off their steam and make impacts in this way, those behaviors make the unstabilizing factor of group incident more obviously[1-3]. How to use of limited resources effectively and information technology integrality, proceed a series of emergency rescues that including project, prevention ,control and handle, improve the reaction capacity and anti-risk capacity for the sudden group incidents, offer more rapid emergency services for the citizens are a unresolved problem for the city managers. Many countries adopt various measures to reduce the damage caused by group incidents, including set up many kinds of mechanism and emergency management system etc, among many ways, set up emergency management system is one of the best effective ways[4].

Design for the feature attributes of the case for the migrant's worker group incident about interest dispute based on CBR

Emergency plan is the core part of the group incident emergency management system in the urban and rural joint areas. Plan Representation for the emergency system based on CBR is also the boot tool in the whole system. The main task of it can be divided into three parts: One, extract and represent of system case attributes; Two, sum up the treatment schemes and solutions in the system cases; Three, estimate and summarize the results of system case processing.

Extract and represent of system case attributes

This dissertation classify and summarize influence factors for interests of migrant workers and draw six fundamental feature attributes by researching and referring to many documents, including

Mei Zhongling[4],Wu Peng[5], Yu Shui,[6] Na,Fan,Xiaoguang[7],Wang Xin[8] and so on, the feature attributes mainly rely on incidents' feature attributes，the dissertation is focusing on the migrant's worker group incidents caused by interest disputes in urban and rural joint areas, according to the basic informations of these events, we can divide the feature attributes into the following six categories, event level, place of incident,cause of incident, scene stability,road condition, local control situation. Feature attributes and categories of emergency plan for the migrant's worker benefit dispute group incident can be classified as the following:

1, Event level : one level, second level, three level, four level

2, Place of incident: office areas of enterprise and public institution, living quarters, downtown areas, vital communication lines and other areas.

3, Cause of incident: wage arrear, inequality of authority , lacking of safeguard measures, uneven distribution of benefits, dissatisfied with the results of related incident, other reasons.

4, Scene stability: scene is stable, emotional fluctuation of the migrant's workers, scenes of chaos but no casualties,scenes of chaos and have casualties

5, The length of road congestion: 0m--20m，20m—50m，50m—80m，80m—150m

6, Plan demand,demand of the emergency department, demand of emergency personnel.

Feature attributes and hierarchical structures of the group incidents caused by worker's interest dispute in the urban and rural joint areas just as the following Fig.2

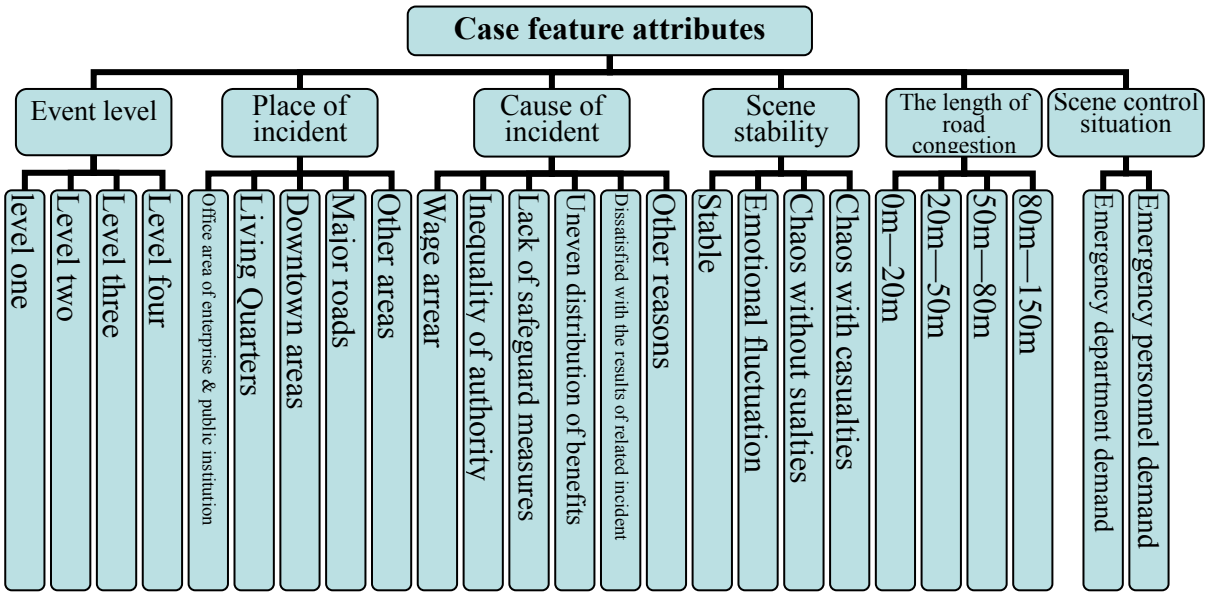

Fig. 1. Feature attributes and hierarchical structure of the migrant's worker group incident emergency management system based on CBR

Case retrieval of the migrant's worker group incident emergency management

There usually can be found one or more events matching with the current group incidents in the case retrieval, hence, case retrieval involves three key questions[9]: first,weight coefficient of feature attributes in the emergency system. Second, similarity matching on feature attributes of cases in emergency system and current group incidents. Third, similarity matching on overall attributes of cases in emergency system and current group incidents .

1. Calculate the weight coefficient on feature attributes of cases

Definitize the layer at the first

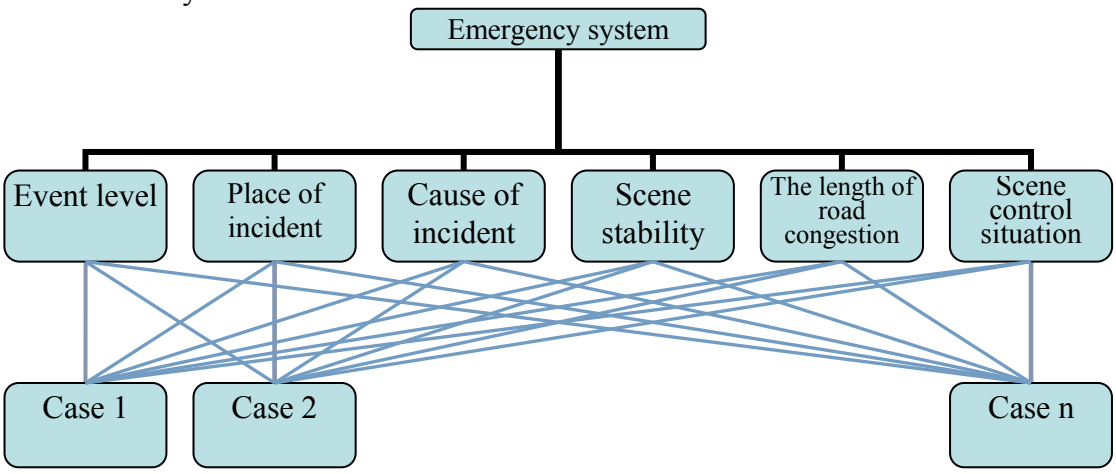

Fig. 2. Hierarchy chart of CBR

Then extract xi and xj from x1,x2,…xn by pairwise comparison and compare their contribution degree for the objective, assign xi/xj in one matrix according to the following scale.

xi/xj＝1， we think xi and xj are same importance.

xi/xj＝3, xi is a little more important than xj

xi/xj＝5， xi is important than xj

xi/xj＝7, xi is lot more important than xj

xi/xj＝9， xi is absolutely great important than xj

When specific value are 2,4,6,8,we think it is in the intermediate state.

The following assignment are based on Analytic Hierarchic Process (AHP).look at the Table. 1

Table 1 : Judgment matrix of weight coefficient on feature attributes of cases

i j	event level	place of incident	cause of incident	scene stability	road condition	Scene control condition
event level	1	1/2	1/4	1/3	1/2	1/3
place of incident	2	1	1/2	2/3	1	2/3
cause of incident	4	2	1	4/3	2	4/3
scene stability	3	3/2	3/4	1	3/2	1
road condition	2	1	1/2	2/3	1	2/3
Scene control condition	3	3/2	3/4	1	3/2	1

According to the chart we can get 6 feature attributes, and according to the attributes, we can obtain the following judgment matrix:

1. list matrix:

$$P=\begin{vmatrix} 1 & 1/2 & 1/4 & 1/3 & 1/2 & 1/3 \\ 2 & 1 & 1/2 & 2/3 & 1 & 2/3 \\ 4 & 2 & 1 & 4/3 & 2 & 4/3 \\ 3 & 3/2 & 3/4 & 1 & 3/2 & 1 \\ 2 & 1 & 1/2 & 2/3 & 1 & 2/3 \\ 3 & 3/2 & 3/4 & 1 & 3/2 & 1 \end{vmatrix}$$

2. normalize each column of the matrix：

$$P=\begin{vmatrix} 1/15 & 1/15 & 1/15 & 1/15 & 1/15 & 1/15 \\ 2/15 & 2/15 & 2/15 & 2/15 & 2/15 & 2/15 \\ 4/15 & 4/15 & 4/15 & 4/15 & 4/15 & 4/15 \\ 1/5 & 1/5 & 1/5 & 1/5 & 1/5 & 1/5 \\ 2/15 & 2/15 & 2/15 & 2/15 & 2/15 & 2/15 \\ 1/5 & 1/5 & 1/5 & 1/5 & 1/5 & 1/5 \end{vmatrix}$$

3. sum up each row of the matrix

$$P=\begin{vmatrix} 2/5 \\ 4/5 \\ 8/5 \\ 6/5 \\ 4/5 \\ 6/5 \end{vmatrix}$$

4. normalize each column of the matrix

$$P=\begin{vmatrix} 0.067 \\ 0.133 \\ 0.267 \\ 0.200 \\ 0.133 \\ 0.200 \end{vmatrix}$$

According to the above calculate, the consequence of weight judgment matrix of 6 feature attributes in group incident is: the max characteristic value of this matrix is $\lambda max=\frac{1}{n}\sum_{x=1}^{n} Wx$ =6 (Wx is weight coefficient of feature attribute x in the group incidents)
W=(0.067,0.133,0.267,0.200,0.133,0.200)T is the weight coefficient of feature attributes, as shown in Table. 2

Table 2 Judgment matrix of weight coefficient on feature attributes of cases(add)

i j	event level	place of incident	cause of incident	scene stability	road condition	Scene control condition	
event level	1	1/2	1/4	1/3	1/2	1/3	0.067
place of incident	2	1	1/2	2/3	1	2/3	0.133
cause of incident	4	2	1	4/3	2	4/3	0.267
scene stability	3	3/2	3/4	1	3/2	1	0.200
road condition	2	1	1/2	2/3	1	2/3	0.133
Scene control condition	3	3/2	3/4	1	3/2	1	0.200

1.1 Consistency judgment of the weight coefficient

Sometimes there will be inconsistent in similarity comparison of current events and cases in case library, so we must conduct the consistency check and the formula is CR=CI/RI.

CR is the rate of random consistency in judgment matrix; CI is the index of general consistency in judgment matrix.the formula of CI is

CI=(λ max- n) /(n- 1) (1)

RI is the index of random consistency in judgment matrix.the value of RI as shown in table 3.

Table 3 RI index of random consistency in judgment matrix

N	1	2	3	4	5	6	7	8	9
RI	0	0	0.58	0.90	1.12	1.24	1.32	1.41	1.45

When CR<0.1 or the maximal characteristic value of this matrix is same with the matrix dimension,we can draw a conclusion the case has the satisfactory consistency, otherwise we need to modify or adjust the value of every feature attributes in the matrix,until make it has the satisfactory consistency.

Mentioned above CI=0<0.1 illustrates the matrix has the satisfactory consistancy.

2 similarity calculation in CBR

Similarity calculation has many ways and there are 5 ways can be chosen for similarity calculation in this paper, numeric type , boolean type, enumerated type, string type , interval type.Similarity calculation model is used for matching the two cases' degree of similarity, and by the calculation and sorting, we can obtain the best matching model of the case at final. The next part will introduce computing methods of various attributes similarity and the overall similarity.

4.2.1 Similarity calculation model of social group incident's attributes.

1. Similarity calculation model in numeric type

$$sim(x_i, y_j)=1-\frac{d_{ij}}{\max(x_i, y_j)}$$

(dij is difference value of xi and yj) (2)

In the formula , similarity value cannot be more than 1, more than 1 means no similarity, if the value is 0,the similarity is inconsistent。X and y must be unified properties. x is the attribute value of current events, y is value of the cases in case library.This formula must be numeric comparison, such as there are 1 emergency personnel in current events and 5 in the cases.

2.Similarity calculation model in boolean type

$$sim(x_i, y_j)=compare(x_i, y_j) \tag{3}$$

(function "compare" is contrasted according to the actually stored value,all the same says 1,different says 0.)X and y represent the unified property only have two values ,the one value is 1 ,it means conformity,the other value is 0, it means disconformity. Generally we use whether judgment,or category judgment, for example,the event took place in Guangzhou,it will mark 1 if there have cases happen in Guangzhou,otherwise mark 0.

3.Similarity calculation model in enumerated type

$$sim(x_i, y_j)=1-\frac{d_{ij}}{\max(R)-\min(R)} \tag{4}$$

Wherein R is the Enum type collection, the discussed enumerated type is regular, it represents apart and regular enumeration difference. X represents one attribute value in current event, y represents corresponding attribute value in the case, similarity can't more than 1. For example, the incident is classified primary, secondary, tertiary, quaternary. The current event is quaternary, case event is secondary, so dij is 2.

4.Similarity calculation model in interval type

$$\mathrm{sim}(x_i, y_j) = 1 - \sqrt{((\min(x_i) - \max(y_i))2 + (\max(x_i) - \max(y_i)2}\Big/_4 \tag{5}$$

X represents one attribute value in current event, y represents corresponding attribute value in the cases, similarity can't more than 1. The formula is suit for scoped attributes. Such as road width is 23m~24m ,22m~23m .

5.Similarity calculation model in string type

$$sim(x_i, y_j)=\frac{t\times l}{\max(len(x_i), len(y_j))} \tag{6}$$

len() represents the length of character in some attributes, t is the matching number, how many times of the same character matching. T guarantees more repetitive more match. L is the matching length of two attributes, that is say how many characters matching with different characters. T guarantees more same characters more match. Similarity can't more than 1, if not it will be invalid. This category is suit for the matching of reason or matching of the fuzzy information.

The overall similarity calculation model of social group incident

There are many kinds of overall similarity calculation model, several common methods are the nearest neighbor algorithm, Tversky function, improved Tversky function, Multi-parameter similarity calculation and so on. The nearest neighbor algorithm is the selected method in this paper, just because it is easy to operate relatively. It is a method that cumulate every attribute value's similarity of the group incidents and thus calculate the the overall similarity. The formula of the overall similarity is :

$$\mathrm{Sim}(A,B)=\sum_{x=1}^{n} Wx\,\mathrm{sim}(Ax, Bx) \qquad m(x=1,2,\cdots,n) \tag{7}$$

Wx is the weight of attribute x ,Ax is the No.x attribute value of current event,Bx is the No.x attribute value of case event,and introduce the weight Wx into the calculation.

You can do the case selection after you gain the overall similarity. Which gain the highest score means it is most similar in the case library.

Case analysis

On September 21, 2011,in the Shantou city of Guangdong province, villagers from Wukan village shouted slogans, pulled banners to demonstrate, they claimed that their lands are occupied and the cadres election is unfair, this event then developed into conflict in that day. Several hundred villagers destroyed the nameplate of the village committee and surrounding facilities. As police began to involve, the incident developed to the conflict with the police. More than 10 policemen were injured,six police car were damaged. Lufeng country set up the temporary emergency working group and launched an investigation, but the villagers disagreed with the announced results.

Result test

The matching case in the case library is "migrant's worker group incident in a factory", the number of participants is about 30 to 99, the location of the event is office area, the reason is wage arrear, scene stability is emotional fluctuation, the length of road congestion is about 10 to 49, the demand of the emergency department is 4,the demand of emergency personnel is 25.

But the participants are more than 100 in the group incident of Wukan village, Shantou city, the location of the event is office area, the cause is uneven distribution of benefits, scene stability is chaos with casualties, the length of road congestion is 10 to 49, the demand of the emergency department is 2, the demand of emergency personnel is 8.

By similarity calculation, translate the matching case to numerical value, as for the participants, set the original case (group incident of Wukan village, Shantou city) is x, the matching case is y. The participant similarity is 0.667; incident location similarity is 1; the cause of incident similarity is 0; scene stability similarity is 0.333; the length of road congestion similarity is 1; the demand of emergency department and personnel similarity is 0.41; and the overall similarity is 0.459289, the result is same with the calculation of matching degree of the system.

Conclusion

This paper analyses the premise of the specific situation of the benefit disputes of migrant's worker in the urban and rural joint areas , extracts 6 feature attributes including event level, place of incident, cause of incident, scene stability, length of road congestion and plan demand, which lays the foundation of establishing the system models. On the basic of 6 feature attributes, we use AHP to establish multi-factors and multi-level decision analysis model, design the CBR system based on J2EE. In the end of paper, we verify the model through the case of Wukan group incident taken place on September 21, 2011. The overall similarity between the test results and given cases in the system is 0.459289. In addition, we take this case to manual CBR process analysis, compare two reasoning results, obtain the higher accuracy and smaller error, which reached the intended effect and proved to be able to conduct effective decision making support based on the current case feature attributes.

Keywords: Equivalent integral equation; Schrödinger equation; Variation of constants method

Abstract. As a milestone method, the inverse scattering transformation is also known as the nonlinear Fourier transformation for solving nonlinear partial differential equations analytically. The equivalent integral equations play a crucial role for the inverse scattering transformation. In this paper, the equivalent integral equations of the static Schrödinger equation are derived by the variation of constants method. The derivation of the equivalent integral equations provides with a necessary help for the beginners to study the inverse scattering transformation method in soliton theory.

Introduction

It is well known that nonlinear complex physical phenomena are often related to nonlinear partial differential equations (PDEs), which are involved in many fields from physics to biology, chemistry, mechanics, etc. As mathematical models of the phenomena, the investigation of exact solutions of nonlinear PDEs will help to understand these phenomena better. With the development of soliton theory, finding exact solutions of nonlinear PDEs has gradually developed into a significant direction in nonlinear science and some effective methods have been proposed and developed, such as the inverse scattering method [1], Bäcklund transformation [2], Hirota's bilinear method [3], homogeneous balance method [4], function expansion methods [5-7]. Among them, the inverse scattering transformation [1] is a systematic method for constructing exact solutions of nonlinear PDEs and recently has received a wide range of applications [8-15] since it was proposed by Gardner, Greene, Kruskal and Miura in 1965 [16].

The inverse scattering transformation is also known as the nonlinear Fourier transformation for solving PDEs, one of its advantages is that it can solve a whole hierarchy of nonlinear PDEs, for example, the KdV hierarchy [17]

$$u_t = T^n u_x,\ \ T = \partial^2 + 4u + 2u_x\partial^{-1},\ \partial = \frac{\partial}{\partial x},\ \partial^{-1} = \frac{1}{2}\left(\int_{-\infty}^{x} \mathrm{d}x - \int_{x}^{\infty} \mathrm{d}x\right),\ \ n = 0,1,2,\cdots \tag{1}$$

associated with a certain spectral problem, namely the static Schrödinger equation

$$\varphi_{xx}(x,k) + u(x)\varphi(x,k) = \lambda\varphi(x,k), \tag{2}$$

where the potential $u(x)$ and their derivatives of any order with respect to x are smooth potential functions which vanish as x tends to infinity, and the following integral

$$\int_{-\infty}^{\infty} |x^j u(x)| \mathrm{d}x, \quad j = 0,1,2 \tag{3}$$

is finite.

Replacing the spectral parameter λ with $-k^2$, Eq. (2) becomes

$$\varphi_{xx}(x,k) + u(x)\varphi(x,k) = -k^2\varphi(x,k). \tag{4}$$

If the integral (3) is convergent, then Eq. (4) exists only a pair of elementary solutions called Jost functions which satisfy the asymptotic conditions

$$\varphi_1(x,k) \sim \mathrm{e}^{ikx}, \quad x \to \infty, \tag{5}$$

$$\varphi_2(x,k) \sim \mathrm{e}^{-ikx}, \quad x \to -\infty. \tag{6}$$

The Jost solutions of Eq. (4) are very important for the inverse scattering transformation method, which are determined by the equivalent integral equations of Eq. (4) when $k \neq 0$

$$\varphi_1(x,k)=\mathrm{e}^{ikx}+\int_x^{\infty}\frac{\sin k(x-s)}{k}u(s)\varphi_1(s,k)\mathrm{d}s\,, \tag{7}$$

$$\varphi_2(x,k)=\mathrm{e}^{-ikx}-\int_{-\infty}^{x}\frac{\sin k(x-s)}{k}u(s)\varphi_2(s,k)\mathrm{d}s\,. \tag{8}$$

Letting $k\to 0$, we can obtain limits of Eqs. (7) and (8)

$$\varphi_1(x)=1+\int_x^{\infty}(x-s)u(s)\varphi_1(s)\mathrm{d}s\,, \tag{9}$$

$$\varphi_2(x)=1-\int_{-\infty}^{x}(x-s)u(y)\varphi_2(s)\mathrm{d}s\,, \tag{10}$$

which give the two cases when $k=0$ of Eqs. (7) and (8).

As a famous method in soliton theory, the inverse scattering transformation method is a milestone in the process of developing analytical methods for solving nonlinear partial differential equations. Without the equivalent integral equations (7) and (8) and their Jost solutions, the inverse scattering transformation could not solve the KdV hierarchy (1). However, to the best of our knowledge, there is not the detailed derivation of Eqs. (7) and (8) in literature.

In this paper, we would like to use the variation of constants method [18] to derive Eqs. (7) and (8) from Eqs. (4)-(6). The rest of this paper is organized as follows. In Section 2, we derive the equivalent integral equatoins (7) and (9) by using the variation of constant method. In Section 3, some conclusions are given.

Derivation of the Equivalent Integral Equations

It is easy to see that when $u(x)\to 0$, Eq. (4) has a pair of elementary solutions e^{-ikx} and e^{ikx}. According to the variation of constants method [18], we suppose that

$$\varphi(x,k)=v_1(x)\mathrm{e}^{-ikx}+v_2(x)\mathrm{e}^{ikx}\,, \tag{11}$$

is an arbitrary solution of Eq. (4).

Substituting Eq. (11) into Eq. (4), we have

$$\varphi_x(x,k)=v_1'(x)\mathrm{e}^{-ikx}-ikv_1(x)\mathrm{e}^{-ikx}+v_2'(x)\mathrm{e}^{ikx}+ikv_2(x)\mathrm{e}^{ikx}\,. \tag{12}$$

Further letting

$$v_1'(x)\mathrm{e}^{-ikx}+v_2'(x)\mathrm{e}^{ikx}=0\,, \tag{13}$$

we have

$$\varphi_{xx}(x,k)=-ikv_1'(x)\mathrm{e}^{-ikx}-k^2v_1(x)\mathrm{e}^{-ikx}+ikv_2'(x)\mathrm{e}^{ikx}-k^2v_2(x)\mathrm{e}^{-ikx}\,. \tag{14}$$

Substituting Eq. (14) into Eq. (4) yields

$$-ikv_1'(x)\mathrm{e}^{-ikx}+ikv_2'(x)\mathrm{e}^{ikx}=-u(x)\varphi(x,k)\,, \tag{15}$$

then solving Eqs. (13) and (15), we can obtain

$$v_1'(x)=-\frac{\mathrm{e}^{ikx}u(x)\varphi(x,k)}{2ik}\,, \tag{16}$$

$$v_2'(x)=\frac{\mathrm{e}^{-ikx}u(x)\varphi(x,k)}{2ik}\,. \tag{17}$$

Taking into account of Eqs. (16) and (17), we select

$$v_1(x)=\int_x^{\infty}\frac{\mathrm{e}^{iks}u(s)\varphi(s,k)}{2ik}\mathrm{d}s+c_1\,, \tag{18}$$

$$v_2(x)=-\int_x^{\infty}\frac{\mathrm{e}^{-iks}u(s)\varphi(s,k)}{2ik}\mathrm{d}s+c_2\,, \tag{19}$$

where c_1 and c_2 are the integral constants.

With the help of Eqs. (18) and (19) we have

$$\varphi_1(x,k)=\int_x^{\infty}\frac{\mathrm{e}^{ik(x-s)}u(s)\varphi_1(s,k)}{2ik}\mathrm{d}s+c_1\mathrm{e}^{-ikx}-\int_x^{\infty}\frac{\mathrm{e}^{-ik(x-s)}u(s)\varphi_1(s,k)}{2ik}\mathrm{d}s+c_2\mathrm{e}^{ikx}\,, \tag{20}$$

In view of the asymptotic conditions (5) and (6), from Eq. (20) we have

$$c_1 = 0,\ c_2 = 1. \tag{21}$$

by setting $x \to \infty$, then Eq. (20) is reduced to

$$\varphi_1(x,k) = \int_x^{\infty} \frac{e^{ik(x-s)} u(s)\varphi_1(s,k)}{2ik} ds - \int_x^{\infty} \frac{e^{-ik(x-s)} u(s)\varphi_1(s,k)}{2ik} ds + e^{ikx}. \tag{22}$$

Employing the equality

$$\frac{\sin k(x-s)}{k} = \frac{e^{ik(x-s)} - e^{-ik(x-s)}}{2ik}, \tag{23}$$

from Eq. (23) we finally obtain Eq. (7).

Similarly, if we select

$$v_1(x) = -\int_{-\infty}^{x} \frac{e^{iks} u(s)\varphi(s,k)}{2ik} ds + c_3, \tag{24}$$

$$v_2(x) = \int_{-\infty}^{x} \frac{e^{-iks} u(s)\varphi(s,k)}{2ik} ds + c_4, \tag{25}$$

where c_3 and c_4 are integral constants to be determined.

$$\varphi_2(x,k) = -\int_{-\infty}^{x} \frac{e^{-ik(x-s)} u(s)\varphi_2(s,k)}{2ik} ds + c_3 e^{-ikx} - \int_{-\infty}^{x} \frac{e^{ik(x-s)} u(s)\varphi_2(s,k)}{2ik} ds + c_4 e^{ikx}, \tag{26}$$

from which we obtain

$$c_3 = 1,\ c_4 = 0. \tag{27}$$

by setting $x \to -\infty$.

In this case, we have

$$\varphi_2(x,k) = \int_{-\infty}^{x} \frac{e^{-ik(x-s)} u(s)\varphi_2(s,k)}{2ik} ds - \int_{-\infty}^{x} \frac{e^{ik(x-s)} u(s)\varphi_2(s,k)}{2ik} ds + e^{-ikx}, \tag{28}$$

from which Eq. (8) can be obtained by the use of Eq. (26).

Conslusion

In summary, we have derived the equivalent integral equations of the static Schrödinger equation (4) by the variation of constants method. Without the equivalent integral equations and their Jost solutions, the inverse scattering transformation could not solve the KdV hierarchy (1). Therefore, the derivation of the equivalent integral equations is necessary and can help the beginners to study the inverse scattering transformation method in soliton theory. How to derive the equivalent integral equations for some other linear spectral problems of the corresponding hierarchies of nonlinear PDEs is worthy of study. This our task in the future.

Keywords: Kink-type solution; MKdV lattice equation; Exp-function method

Abstract. In this paper, the exp-function method is improved for constructing exact solutions of nonlinear differential-difference equations with variable coefficients. To illustrate the validity and advantages of the improved method, the mKdV lattice equation with an arbitrary function is considered. As a result, kink-type solutions are obtained which possess rich spatial structures. It is shown that the improved exp-function method can be applied to some other nonlinear differential-difference equations with variable coefficients.

Introduction

In 2006, He and Wu [1] proposed the so-called exp-function method to obtain solitary solutions and periodic solutions of nonlinear partial differential equations (PDEs). Since the method was proposed, it has been widely applied to many nonlinear PDEs [2-13]. More and more studies show that the exp-function method with computer symbolic computation is available for many kinds of nonlinear PDEs and can be used to construct different types of exact solutions due to its more general ansätz:

$$u(\xi)=\frac{\sum_{n=-f}^{g} a_n \exp(n\xi)}{\sum_{m=-p}^{q} b_m \exp(m\xi)}, \quad \xi=\sum_{i=1}^{s} k_i x + wt \tag{1}$$

employed for a given $(s+1)$-dimensional nonlinear PDEs with independent variables $t, x_1, x_2, \cdots, x_s$ and dependent variable u, here a_n and b_m are undermined constants, f, p, g and q can be determined by balancing the highest order linear term with the highest order nonlinear term in Eq. (1). He and Wu [2] showed through several instances that the final solution does not strongly depend on the choices of values of f, p, g and q. It was observed that the relations $f=p$ and $g=q$ are usually obtained and $f=p=g=q=1$ is the simplest choice and makes the exp-function method more straightforward.

Since the work of Fermi *et al.* in the 1950s [14], the investigation of exact solutions of nonlinear differential-difference equations (DDEs) has played a crucial role in the modelling of many phenomena in different fields which include condensed matter physics, biophysics and mechanical engineering. Unlike difference equations which are fully discretized, DDEs are semi-discretized with some of their spacial variables discretized while time is usually kept continuous. Generally speaking, it is hard to generalize one method for nonlinear PDEs to solve nonlinear DDEs because of the difficulty to search for iterative relations from indices n to $n\pm1$.

The present paper is motivated by the desire to propose an improve version of the exp-function method for constructing exact solutions of nonlinear DDEs with variable coefficients. In order to illustrate the validity and advantages of the improved method, the mKdV lattice equation with an arbitrary function

$$\frac{du_n(t)}{dt}=[\alpha(t)-u_n^2](u_{n+1}-u_{n-1}), \tag{2}$$

is considered, here $u_n = u(n,t)$, $n \in Z$, $\alpha(t)$ is an arbitrary function of t. When $\alpha(t) = 1$, Eq. (2) becomes the known mKdV lattice equation [15]. As a result, kink-type solutions are obtained which possess rich spatial structures.

Methodology

For a given nonlinear DDEs

$$E(u_{nt}, u_{nx}, u_{ntt}, u_{nxt}, \cdots, u_{n-1}, u_n, u_{n+1} \cdots) = 0, \tag{3}$$

we take the following transformation

$$u_n = U_n(\xi_n), \ \xi_n = dn + c(t) + \omega, \tag{4}$$

where d is a constant to be determined later, $c(t)$ is an undetermined function of t, ω is an arbitrary function, then Eq. (3) can be reduced to

$$F(U_n', U_n'', \cdots, U_{n-1}, U_n, U_{n+1}, \cdots) = 0. \tag{5}$$

The ansätz used to improve the exp-function method presented in this paper for Eq. (5) is expressed in the following form:

$$U_n = \frac{a_{-1}\exp(-\xi_n) + a_0 + a_1\exp(\xi_n)}{b_{-1}\exp(-\xi_n) + b_0 + b_1\exp(\xi_n)}, \tag{6}$$

$$U_{n-1} = \frac{a_{-1}\exp(-\xi_n)\exp(d) + a_0 + a_1\exp(\xi_n)\exp(-d)}{b_{-1}\exp(-\xi_n)\exp(d) + b_0 + b_1\exp(\xi_n)\exp(-d)}, \tag{7}$$

$$U_{n+1} = \frac{a_{-1}\exp(-\xi_n)\exp(-d) + a_0 + a_1\exp(\xi_n)\exp(d)}{b_{-1}\exp(-\xi_n)\exp(-d) + b_0 + b_1\exp(\xi_n)\exp(d)}, \tag{8}$$

where a_{-1}, a_0, a_1, b_{-1}, b_0 and b_1 are all undetermined constants.

Substituting Eqs. (6)-(8) into Eq. (5) yields and equating the coefficients of all powers of $\exp(j\xi_n)$ $(j = 0, \pm1, \pm2, \cdots)$ to zero yields a set of equations for a_{-1}, a_0, a_1, b_{-1}, b_0, b_1, d and $c(t)$, solving the system of differential equations we can determine the solution (4) of Eq. (3) by use of Eqs. (6)-(8).

Kink-Type Solutions

For the mKdV lattice equation (2), we use the transformation (4), then it is reduced to

$$c(t)U_n' = [\alpha(t) - U_n^2](U_{n+1} - U_{n-1}). \tag{9}$$

Substituting Eqs. (6)-(8) into Eq. (15), we derive a set of equations for a_{-1}, a_0, a_1, b_{-1}, b_0, b_1, d and $c(t)$:

$$3a_{-1}^2 b_{-1} d + a_{-1} b_{-1}^2 d^3 = 0, \tag{10}$$

$$3a_0^2 b_0 d + a_0 b_0^2 d^3 - 8a_0 b_1 b_{-1} d^3 - \frac{8}{3} b_0 b_1 b_{-1} d^5 = 0, \tag{11}$$

$$-a_0 b_1^2 c - \frac{b_0 b_1^2 c^2}{3d} + \frac{1}{3} b_0 b_1^2 c d^2 + a_0 b_1^2 d^3 = 0, \tag{12}$$

$$a_0 a_1^2 \mathrm{e}^d - a_1^3 b_0 \mathrm{e}^d - a_0 c \mathrm{e}^{2d} + a_1 b_0 c \mathrm{e}^{2d} - a_0 a_1^2 \mathrm{e}^{3d} + a_1^3 b_0 \mathrm{e}^{3d} - a_0 \mathrm{e}^{\alpha(t)} + a_1 b_0 \mathrm{e}^{\alpha(t)} - a_1 b_0 \mathrm{e}^{3\alpha(t)} = 0, \tag{13}$$

$$\frac{27 a_0^3}{4d} - 12 a_0 b_1 b_{-1} d^3 = 0, \tag{14}$$

$$3a_0^2 b_{-1} d - a_0 b_0 b_{-1} d^3 - \frac{2}{3} b_0^2 b_{-1} d^5 = 0. \tag{15}$$

Solving the system of differential equations (10)-(15), we obtain the following results:

$$a_0 = 0, \ a_1 = \pm\sqrt{\alpha(t)}\tanh(d), \ a_{-1} = \mp b_{-1}\sqrt{\alpha(t)}\tanh(d), \tag{16}$$

$$b_0 = 0, \ c(t) = 2\tanh(d)\int \alpha(t)\mathrm{d}t, \tag{17}$$

where b_{-1} is an arbitrary constant.

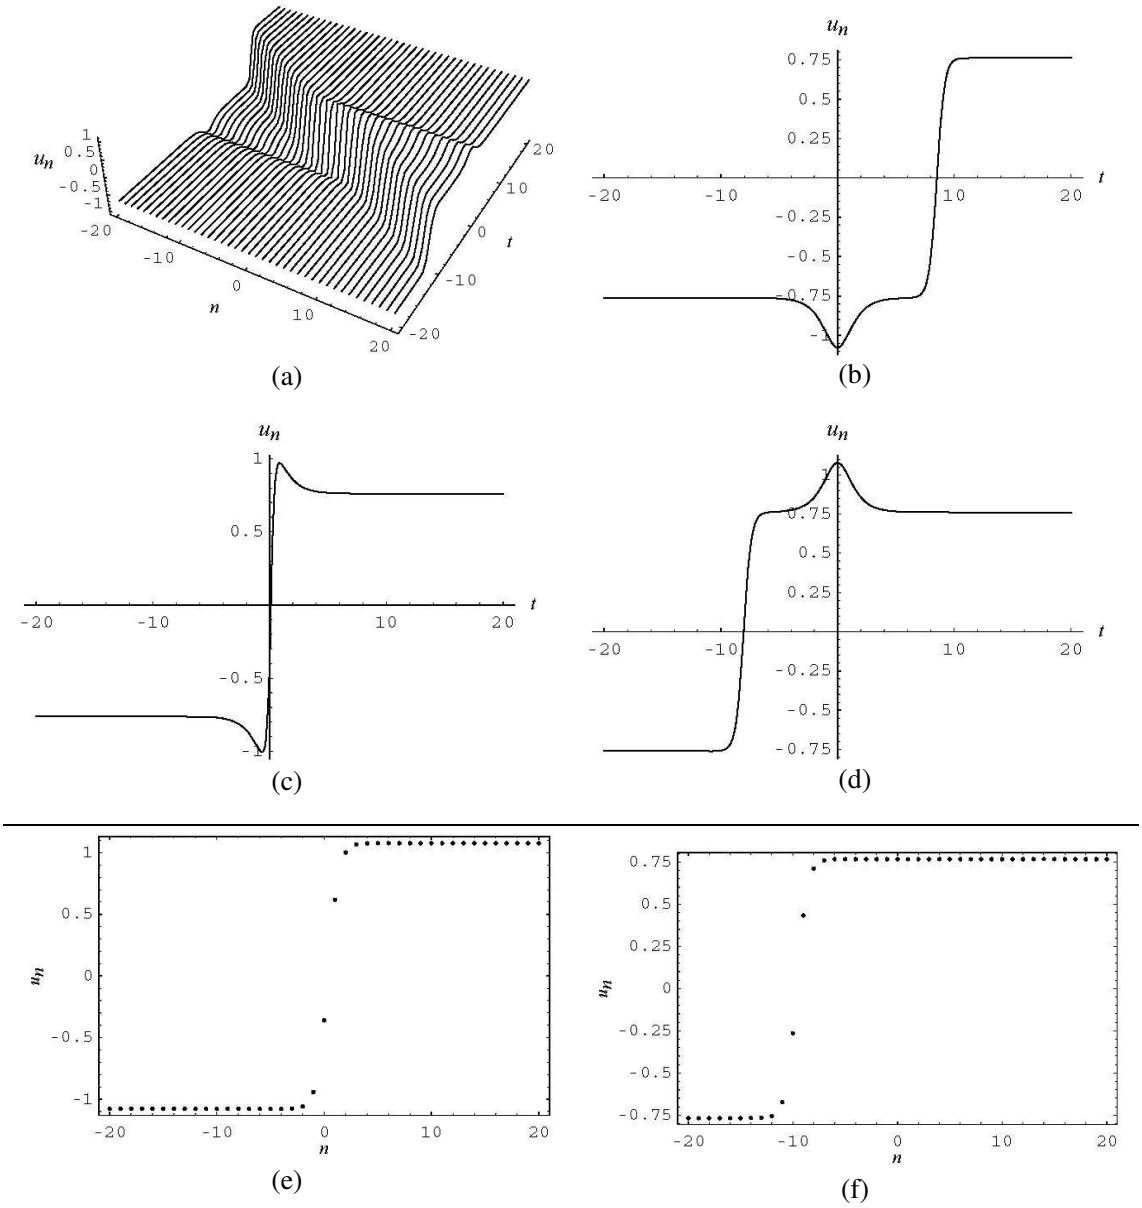

Fig. 1. Spatial structure of solution (18) with (+) branch: (a) $n=[-20,20]$, $t=[-20,20]$; (b) $n=-15$, $t=[-20,20]$; (c) $n=0$, $t=[-20,20]$; (d) $n=15$, $t=[-20,20]$; (e) $n=[-20,20]$, $t=0$; (f) $n=[-20,20]$, $t=5$.

Then we obtain a pair of new kink-type solutions of Eq.(2):

$$u_n=\pm\sqrt{\alpha(t)}\tanh(d)\frac{\exp(\xi_n)-b_{-1}\exp(-\xi_n)}{\exp(\xi_n)+b_{-1}\exp(-\xi_n)}, \tag{18}$$

where $\xi_n=dn+2\tanh(d)\int\alpha(t)\mathrm{d}t+\omega$.

In Fig. 1, a spatial structure of solution (18) is shown, where we selected $\alpha(t)=1+\mathrm{sech}t$, $b_{-1}=2$, $d=1$, $\omega=0$.

Conclusions

In this paper, an improvement on the exp-function method is proposed for nonlinear DDEs with variable coefficients. To show the advantage of the improved method, the mKdV lattice equation with an arbitrary function is considered. As a result, a pair of kink-type solutions are obtained. To the best

of our knowledge, the obtained solutions have not been reported in literature. It may be important to explain some physical phenomena. It is shown the improved exp-function method can be applied to some other nonlinear DDEs with variable coefficients.

Keywords: Paraphrase; Similarity Calculation; Double Negation.

Abstract. By using part of speech information to similarity calculation of paraphrase sentences, the similarity calculation method is improved. The improved method includes multi information of paraphrase text, such as, matching words information and part of speech information. A small-scale comparing experiment of double negation sentence paraphrase for two method of similarity calculation has been done, and the experimental results indicated effect of improvement method.

Introduction

With computer networks are rapidly developing, society is becoming internationalized quickly. However the language information processing is the most important research domain in this information society. Paraphrasing is a very important research topic in research of NLP. It is able to use on a lot of fields and its use can improve the processing performance of the system [1][2], such as question answer [3], text reading assistance [4], information retrieval [5] and other fields. Its use can improve the processing performance of the system. It is very significant to research sentence paraphrase.

About research of Chinese sentence paraphrase, Li et al. proposed a template representation and generalization method, it represent paraphrasing template with semantic code of words and extract slot word by using a dependency parser, using search engine to generalize paraphrasing examples[6]. Zhao et al. proposed a method that acquires context-specific lexical paraphrases automatically, the method obtains paraphrases of a word depend on the specific sentence the word occurs in, extract candidate paraphrase by web mining [7]. Zong et al. proposed a method of spoken Chinese paraphrasing, extracting feather of input utterance by analysis phrase structure and chunk dependency of an utterance, finally got paraphrasing of input based on the analysis result [8].

Although the paraphrase research of English and Japanese has achieved many results, Chinese language is neither like English which characterizes by tense, person, declension, etc., nor like Japanese which characterizes by case-auxiliary word and declension, the research of Chinese sentence paraphrase cannot use the same technique that process English or Japanese. Sentence structure and empty words play a key role in Chinese expression.

This paper improved the calculation method of similarity of paraphrase sentences, and made use of the method to the paraphrase of Chinese double negative sentence. At first, the paper introduces Chinese double negative sentences. Then paraphrase templates are extracted by analyzing sentence structure. The matching of paraphrase template with original sentences is by calculating similarity.

Structure of Double Negative Sentences

A double negative sentence has two forms of negation that is used in the same sentence. In double negative sentences, double negatives cancel one another and produce an affirmative sense.

Mandarin Chinese also employs litotes in a like manner. For example, 'I do not dislike.' can express by 'I certainly like. '.

A double negative sentence has three expression functions. It can express affirmation, emphasis and euphemism. For the three kinds of double negative sentences, the structures are: double negation consists of two negative adverbs of using together; double negation consists of a negative adverb and a verb that has negative meaning; double negation consists of a negative adverb (or a verb that has negative meaning) and tone of one's voice when asking a rhetorical question.

We use the word segmentation and part-of –speech tagging tool to analyze those double negative sentences [9], and compare original sentences with paraphrase sentences to extract paraphrasing templates.

Classification of Double Negative Sentences

Here the double negative sentences are classified to three kinds of structures: use two negative adverbs; use a negative adverb and a verb that has negative meaning; use a negative adverb (or a verb that has negative meaning) and tone of one's voice when asking a rhetorical question. That is to say, there are three kinds of double negative sentence.

Semantic Analysis of Double Negative Sentences

We use the word segmentation and part-of–speech tagging tool to analyze those double negative sentences, and compare original sentences with paraphrase sentences to extract paraphrasing templates. The analysis results of double negative sentences are as following table 1.

In the table 1, '*' is words that does not effect sentence meaning and can be exchanged by other words. In addition rr, nr, w, v, d, dy and n are POS of words of corresponding position.

Paraphrase Templates of Double Negative Sentences

Table 1 shows double negative paraphrase templates that are generally used. For example, the paraphrase sentence of 'wo bu de bu qu tushuguan kanshu.' (I have to go to library to read book.) can be expressed by 'wo qu tushuguan kanshu.', 'wo bixu qu tushuguan kanshu.', 'wo yinggai qu tushuguan kanshu.' and so on. The paraphrase templates can complete those paraphrasing process.

Table 1. A part of Paraphrase Templates

Key words	Paraphrase key words	Paraphrase templates
budebu	Bixu, yinggai,	If (rr/nr/r)+bunengbu, buhuibu, budebu, buyaobu
bunengbu	Yiding, bixu,	buchengren+(rr/nr/r)+(*), then (rr/nr/r)+X+(rr/nr/r)+(*)
buhuibu	Queshi, yinggai	and X={neng, yinggai,keyi,budebuchengren: chengren,
buyaobu	Yao, gai, shi	yinggaichengren, bixuchengren}
Buwu, wubu	Dou, you	If (*), v+(rr/nr/n)+buwu, wubu, weibibu,
weibibu	ye	nandaobu,bushimei, zenmebu+v+y+？ then (*),
bushimei	haishiyou	v+(rr/nr/n)+X+v. and X={you, dou, zenmebu=0 }

Similarity calculation of Templates Matching

Similarity calculation is used to match part of speech of sentence and key word of double negative part. The key word that is the double negative part in a sentence is called key item. The sequence of POS of a sentence is called POS sequence. The match of key item carries out by comparing original sentence with template. And the match of POS sequence is completed by calculating number of same POS between original sentences with template. Then the match of original sentence with template carries out by two steps, key item and POS sequence.

The procedure of paraphrase matching is to extract the structure frame of source sentence, to compute the similarity between the original sentence and the paraphrasing template, to decide paraphrasing template of using paraphrasing. Similarity of a sentence is different with a text or paragraph. The number of words in a sentence is limited, and there are repeated words hardly.

We estimate the similarity of paraphrase sentence with paraphrase template is according to (a) part of speech series of two sentences; (b) key items, the key items are common words that involved in paraphrase sentence and paraphrase template. The calculation formula is as follow (1).

$$STSim = (STN \cdot \alpha + \frac{SWN(T,S)}{TWN(T)} \cdot \beta) \times 100 \quad (1)$$

Here STN is number of same POS of the being paraphrased sentence to compare with the template; SWN is the number of key item of the being paraphrased sentence to compare with the template; TWN is the number of key item in the template; STSim is the similarity of the being paraphrased sentence to match with the template. Where α and β are weighted parameter.

In the template matching procedure, matching STN and key items must consider the order of words. By extracting sentence structure of source sentences and comparing with templates, we can get the number of matching key items, the number of POS in the source sentence, and the number of key items, the number of POS in the corresponding templates. Then, the similarity between the source sentence and the templates is obtained.

Experiment and Evaluation

We evaluated the performance of the paraphrase method by a small scale data. We used 500 sentences to paraphrasing experiment. The experiment is based on 15 kinds of templates; each kind of template is divided into several more idiographic templates, there are total of 85 templates. The paraphrase is not one-to-one, but one-to-many. That is, one sentence will be paraphrased to several sentences.

The paraphrase results are the correct paraphrasing rate 80% and the erroneous paraphrasing rate 15.5%. The main reason of wrong paraphrase is the problem of similarity calculation. The error template is selected at a lower similarity because there is not template that matches with original sentence.

We extract 100 sentences at random from the paraphrase results; to review the reason of wrong paraphrase. The reason of wrong paraphrase is because of wrong word segmentation, the template matching error includes wrong template extraction and the inaccuracy of similarity calculation. This shows the need for longer sentence paraphrase approach should be further explored.

We compare the results of sentence paraphrase that use method of similarity calculation of paper [10] with this paper respectively. The results of two method of similarity calculation are shown in figure 1.

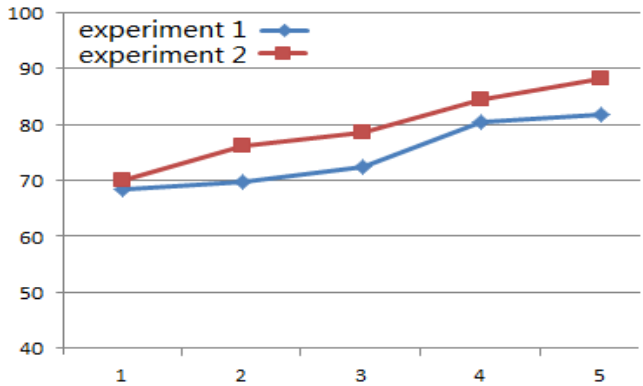

Fig.1. The experimental results of Similarity calculation

The improvement method and original method of similarity calculation are experiment1 and experiment2. Figure 1 shows the paraphrase correct rate of two experiments. According to figure 1, the improvement method of similarity calculation is impactful.

Conclusion

For the paraphrase problem of double negative sentences, we use the method based on templates and use the improved method of similarity calculation of matching templates. We have classified the double negative sentences to three kinds, and analyzed the structure of each kind of double negative sentences. We compare the syntax structure of double negative sentences with their affirmation sentences to extract the paraphrase templates.

The similarity calculation are consists of part of speech of sentence, key word of double negative part and key item. The match of key item carries out by comparing original sentence with template. And the match of part of speech is completed by calculating original sentence with template.

To evaluate the performance of proposed implement method of similarity calculation, we have carried out a small scale experiment. The experimental results indicated the method added the part of speech to similarity calculation is effective. The method has achieved a result of precision 85.4% and recall ratio 92.6%. Because of the templates are not enough and some sentences cannot paraphrase and make some mistakes in paraphrase.

For the future we will research the similarity calculation method of two sentences. Because of the number of words in a sentence is little, we think it is different from the similarity calculation of paragraph or common text.

[a]email: zx38610@yeah.net

Keywords: SPH; water fluid; simulation

Abstract. An improved SPH method for water fluid simulation was proposed in this paper. We used higher order splines to improve the stability, and two layers virtual particles to solve particle inconsistency problem near the boundary area. Due to the improvements paid more attention on details, we obtained more realistic and stalbe effect, which was different with previous works. Experimental results showed that our method was realistic, and could achieve real-time frame rate when particle amount was less than 10000.

Introduction

Water fluid simulation has long been an important research in computer graphics for almost twenty years, which greatly enhances the expressiveness of virtual world of games, military simulation, 3D film and so on. There are two kinds of method have been used for fluids simulation in computer graphics nowadays, one is the Euclidian approach, and the other is the Lagrange approach. In this paper, we adopt the idea of SPH(Smoothed Particle Hydrodynamics) to simulate water and floating body, which belongs to the Lagrange methods.

We pay more attention on details in order to obtain more realistic effect, which we called special treatment. That made it different with previous works aimed at improving the simulation speed. The next section of this paper describes previous related works. SPH summary is presented in Section 3. Section 4 introduces our special treatments of improved SPH method for realistic effect. The experiments and results are reported in Section 5. Section 6 closes with conclusions and future work.

Related Works

SPH as a particle-based pure Lagrange interpolation method was first proposed by [1] for the simulation of astrophysical problems. Monaghan [2] first studied on fluid simulation with SPH method. In 1995, Stam [3] firstly used SPH to simulate fire and gaseous phenomena. Muller [4] proposed an interactive method based on SPH to simulate pouring water into glass with free surfaces, which allowed for realtime interaction with 5000 particles. Then Muller [5] simulated bubble rising motion in water with SPH. Paper [6] presented an prediction-correction incompressible fluid simulation method based on SPH which is more expensive to compute, but it can use large time steps significantly. A multiphase model for simulating water and air bubbles with SPH presented in paper [7].

Generally, the more particles that are used, the smaller the damping artifacts and the more small-scale details like splashes, spray, and surface waves can be reproduced. However, doubling the resolution of a simulation increases the particle number by a factor of 8. This increases the computational cost notably since it depends linearly on the number of particles. Therefore, much work has been done in improving the computational efficiency of the solver by using for example GPU implementations, e.g. [8], or by level of detail techniques, e.g. [9]

However, few improvements have been proposed to treat the smoothing function and solid boundary which are very important to stability and reality. Therefore, we take care in these regards with improved kernel function and solid boundary treatment in the following part.

SPH Summary

SPH Approximation Techniques

SPH is an interpolation method for particle systems. The state of fluid system is represented by a set of particles, and fluid advection is calculated by particle movement.

With SPH, field quantities that are only defined at discrete particle locations can be evaluated anywhere in space. For this purpose, SPH distributes quantities in a local neighborhood of each particle using radial symmetrical smoothing kernels. According to SPH, continuous physical field is approximated in equation (1), and a discrete quantity $f(x_i)$ and its derivative are interpolated at location x by a weighted sum of contributions from all particles within support domain as following equations (2)-(4) :

$$f(x)=\int_{\Omega} f(x')W(x-x',h)dx' \tag{1}$$

$$f(x_i)=\sum_{j=1}^{N}\frac{m_j}{\rho_j}f(x_j)W(x_i-x_j,h) \tag{2}$$

$$\nabla f(x_i)=-\sum_{j=1}^{N}\frac{m_j}{\rho_j}f(x_j)\nabla W(x_i-x_j,h) \tag{3}$$

$$\nabla^2 f(x_i)=-\sum_{j=1}^{N}\frac{m_j}{\rho_j}f(x_j)\nabla^2 W(x_i-x_j,h) \tag{4}$$

where， x is position, Ω is integral volume, x' is a position in Ω, h is the support domain radius, $W(x-x',h)$ is the smoothing kernel function, $f(x_i)$ is the quantity of particle i at position x_i, x_i is the particle position in the supporting domain of particle i.

Special Treatments

More Stable Smoothing Function

In the SPH method, the smoothing function is used for kernel and particle approximations. It is of utmost importance in the SPH method as it determines the pattern to interpolate, and defines the cut-off distance of the influencing area of a particle.

The most frequently used smoothing function as following equation (5) may be the cubic B-spline function, which was originally used by Monaghan and Lattanzio[10].

$$W(R,h)=\alpha_d\times\begin{cases}\frac{2}{3}-R^2+\frac{1}{2}R^3, & 0\le R<1,\\ \frac{1}{6}(2-R)^3, & 1\le R<2,\\ 0, & R\ge 2.\end{cases} \tag{5}$$

In one-, two- and three- dimensional space, αd=1/h, 15/7πh2 and3/2πh3, respectively. The cubic splinefunction has been the most widely used smoothing function in the emerged SPH literatures since it closely resembles a Gaussian function while having an arrower compact support. However, the second derivative of the cubic spline is a piecewise linear function, and accordingly, the stability properties can be inferior to those of smoother kernels.

We used the following higher order splines, such as equation (6) that are more closely approximating the Gaussian and more stable [11].

$$W(R,h)=\alpha_d\times\begin{cases}(R+2.5)^4-5(R+1.5)^4+10(R+0.5)^4, & 0\le R<0.5,\\ (2.5-R)^4-5(1.5-R)^4, & 0.5\le R<1.5,\\ (2.5-R)^4, & 1.5\le R<2.5,\\ 0, & R>2.5,\end{cases} \tag{6}$$

This was regarded as an important improvement over the cubic spline function, and relieve the problem of compressive instability.

Solid Boundary Treatment

The conventional SPH model suffers from particle inconsistency near the boundary area. Only particles inside the boundary contribute to the summation of the particle interaction, and no contribution comes from the outside since there are no particles beyond the boundary. This one-sided contribution does not give correct solutions, because on the solid surface, although the velocity is zero, other field variables such as the density are not necessarily zero.

We used two layers virtual particles to implement the solid boundary conditions, which were allocated on and outside the boundary. These virtual particles were classified into two categories, virtual particles that were located right on the solid boundary (Type I) and virtual particles that were outside the boundary (Type II) (see Fig. 1). Type I virtual particles were used to exert a repulsive boundary force on approaching fluid (real) particles to prevent the interior particles from penetrating the boundary. The penalty force is calculated using a similar approach for calculating the molecular force of Lennard-Jones form [12]. If a Type I virtual particle is the neighboring particle of a real particle that is approaching the boundary, a force is applied pairwisely along the centerline of these two particles as following equation (7)

$$PB_{ij} = \begin{cases} D[(\frac{r_0}{r_{ij}})^{n_1} - (\frac{r_0}{r_{ij}})^{n_2}]\frac{x_{ij}}{r_{ij}^2}, & (\frac{r_0}{r_{ij}}) \le 1, \\ 0, & (\frac{r_0}{r_{ii}}) > 1. \end{cases} \tag{7}$$

Where the parameters n1 and n2 are empirical parameters, and are usually taken as 12 and 4 respectively. D is a problem dependent parameter, and should be chosen to be in the same scale as the square of the largest velocity. The cutoff distance r0 is important in the simulation. It is usually selected approximately close to the initial particle spacing. To more effectively prevent fluid particles from penetrating the solid wall, Type I virtual particles are usually more densely distributed at the solid boundary than the fluid particles (as in Fig. 1).

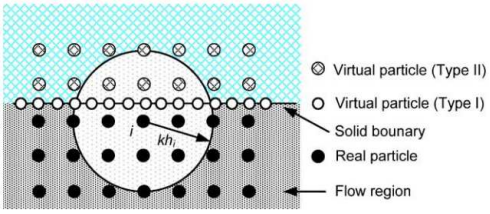

Fig.1 Schematic illustration of particle distribution near solid boundary

Type II virtual particles are usually obtained through reflecting the real fluid particles along the solid boundary. Scalar properties of the virtual particles can be taken as the same as the reflected real particles, while velocity of the virtual particles are usually taken as opposite of the reflected counterparts. As such the non-slip boundary condition is implemented. Due to the compactness of the smoothing kernel function, only the real particles that are within κh to the solid boundary are necessary to be reflected to form Type II virtual particles.

Implementation

Experiments are carried out with VC++6.0 and OpenGL on the Windows XP platform. And with Intel CPU PIV 3.0 GHz, 1GB RAM, GeForce 7300 display card and 512M display memory.

In our experiments, a block of wood is poured into a glass of water. To make it simple, water and the block of wood are drew, ignoring the glass. Figure 2 show the surface shaking when thrown a block of wood. Our experiments can reach interaction performance when the number of particles below 10000.

Fig.2 Simulation result

Conclusions and Future Work

An improved SPH method for simulating water and floating body interaction was proposed in this paper. We use a more stable smoothing function and virtual particles on solid boundary for stability and reality. Experimental results showed that our method was realistic, and could achieve real-time frame rate when particle amount was less than 10000. Our method can be easily integrated into an existing particle solver to improve the computational stability and efficiency.

Keywords: Convergence speed; Markov chain; Expected convergence time

Abstract. Although theoretical result of convergence for improved generalized ant colony optimization (IGACO) algorithm has been proved in recent years, the convergence speed is also an open and difficult problem. This article, based on the Markov model, tries to explore the analysis of convergence speed for IGACO algorithm. Some experiments have been studied to compare the convergence speed between ant colony optimization (ACO) algorithm and IGACO algorithm.

Introduction

Ant colony optimization (ACO) algorithm [1] has been studied for many years. Generalized ant colony optimization (GACO) algorithm has been proposed in [2]. In literature [2], two strictly increasing functions have been presented to model the behavior for describing the pheromone update rules. Compared with ACO algorithm, GACO algorithm generalizes the mathematical expression form of probability selecting the next node. Literature [2] has proved a theorem for describing the convergence of GACO algorithm. Based on GACO algorithm, a new improved generalized ant colony optimization algorithm (IGACO algorithm) has also been proposed in [3]. In literature [3], the selected probability function has been further generalized from the family of strictly increasing continuous function to the family of bounded function, which gives a more general form of expression for the probability of selecting the next node. An important theorem of convergence for IGACO algorithm was also proved, i.e. for a sufficiently large number of algorithm iterations, the probability of finding the globally optimal solution at least once tends to 1. On the other hand, literature [3] proposed a new asymptotic balance principle of pheromone. In the pheromone update rule, the residual rate function of pheromone and the global increasing function of pheromone ware presented. Literature [3] proved that the residual pheromone tends to a positive number on the edges that are globally optimal solution, and tends to 0 on the edges that are not globally optimal solution.

Although IGACO algorithm may become more widespread approach because its generalization, the convergence speed is also an open and difficult problem. This paper tries to analyses the convergence speed for IGACO algorithm.

Finally, the computational simulation show that, compared with ACO algorithm algorithm, the IGACO algorithm has good performance on convergent speed.

Theoretical Analysis of the Convergence Speed for IGACO Algorithm

First, create a Markov process model of IGACO algorithm [4].

Let the state variable be $X(t)=(S(t),T(t))$, $S(t)=\{S_{bs}(t)\cup S_{iter}(t)\}$, where $S_{bs}(t)$ is the current global optimal solution, $S_{iter}(t)$ means a full iteration required to complete the solution set, and $T(t)$ is the pheromone vector.

Base on the Definition and pheromone update rule of IGACO and the definition of continuous-time Markov chain can obtain that $X(t)$ is defined as the availability of continuous-time Markov chains.

Expected First Hitting Time: set an absorbing Markov process states $\{X(t)\}_{t=0}^{+\infty}$ ($\forall X(t)=(S(t),T(t))\in I$) and optimal state space $I^*\in I$; If ν is a random variable and meets: When $t=\nu$, $X(t)\in I^*$, when $0\le t<\nu$, $X(t)\notin I^*$. Then $E\nu$ is the expected first hitting time.

Theorem 1. 1 The absorbing Markov process corresponding to IGACO algorithm is $\{X(t)\}_{t=0}^{+\infty}$, its state space is I, which corresponds to the optimal state space I^*. If $\phi(t_m)=P\{X(t_m)\in I^*\}$ and $\lim_{t_m\to\infty}\phi(t_m)=1$, then the convergence speed of IGACO is $E\lambda=\sum_{t=0}^{+\infty}(1-\phi(t))dt$.

According to Theorem 1. 1, if the $\forall t_m=1,2,\cdots,\phi(t_m)$ or $P\{\nu=t_m\}=\phi(t_m)-\phi(t_{m-1})$ is known, you can accurately calculate the expected convergence time of IGACO through the formula, which can measure the convergence speed of the algorithm. But in fact, $\phi(t_m)$ is difficult to determine.

Given the IGACO algorithm corresponding absorbing Markov state process $\{X(t)\}_{t=0}^{+\infty}$, the corresponding optimal state space is I^*, if $\phi(t_m)=P\{X(t_m)\in I^*\}$ meets $a(t)\le \mathrm{P}\left\{X(t_m)\in I^*\middle|X(t_{m-1})\notin I^*\right\}\le b(t)$, and because IGACO meets absorbing state Markov process model, so $P\{X(t_m)\in I^*\mid X(t_{m-1})\in I^*\}=1$. According to the total probability formula and Theorem 1. 1 , we can obtain that,

$$\sum_{t_m=0}^{+\infty}[(1-\phi(0))\prod_{t_m=1}^{+\infty}(1-b(t))]\le E\lambda\le\sum_{t_m=0}^{+\infty}[(1-\phi(0))\prod_{t_m=1}^{+\infty}(1-a(t))] \tag{1}$$

Corollary 1. 1 Given the IGACO algorithm corresponding absorbing Markov state process $\{X(t)\}_{t=0}^{+\infty}$, the corresponding optimal state space is I^*, if $\phi(t_m)=P\{X(t_m)\in I^*\}$ meets $\mathrm{a}(t)\le P\left\{X(t_m)\in I^*\middle|X(t_{m-1})\notin I^*\right\}\le b(t)$ and $\lim_{t_m\to\infty}\phi(t_m)=1$.The expectations of convergence time $E\lambda$ of IGACO algorithm meets

$$b^{-1}[1-\phi(0)]\le E\lambda\le a^{-1}[1-\phi(0)] \tag{2}$$

Assuming optimal solution in the k iteration cycle, then the optimal solution sequence of nodes is $r(t),ck1,ck2,\cdots,ckn,d(t)$, where t is the time parameters, $r(t)$, $d(t)$ respectively for the moment t the source and destination nodes, the optimal solutions in the k iteration, the probability is

$$P(t,s^*)=P(r(t),ck1(t),ck2(t),\cdots,ckn(t),d(t))=\prod_{j=1}^{n+1}P_{kj} \tag{2}$$

There in $P_{k1}=P(r(t),ck1(t)),P_{k2}=P(ck1(t),ck2(t)),\cdots,P_{k(n+1)}=P(ckn(t),d(t))$, s^* is the optimal solution; each selected P_{kj} is calculated by the probability function.

Assuming IGACO algorithm has m ants, according to the above derivation can compute the probability to find the optimal solution in the k iteration cycle:

$$P_t=P\{X(t)\in Y^*\mid X(t-1)\notin Y^*\}\quad=1-(1-P(s^*))^m\quad=1-(1-\prod_{j=1}^{n+1}P_{kj})^m \tag{3}$$

When $t=1,2,\cdots,j=1,2,\cdots,n$, $0<P_{\min}\le P_{kj}\le P_{\max}$,

$$\begin{aligned}&P_t=P\{X(t)\in Y^*\mid X(t-1)\notin Y^*\}\ge 1-(1-P^n{}_{\min})^m\\&P_t=P\{X(t)\in Y^*\mid X(t-1)\notin Y^*\}\le 1-(1-P^n{}_{\max})^m\end{aligned} \tag{4}$$

By the formula (2) we have，

$$[1-\phi(0)][1-(1-P_{\max}^n)^m]^{-1}\le E\lambda\le[1-\phi(0)][1-(1-P_{\min}^n)^m]^{-1} \tag{5}$$

Because during the initialization of the algorithm, $S(t)=\{S_{bs}(t)\cup S_{iter}(t)\}=\varnothing$, so $\phi(0)=0$。

By the analysis above, we can obtain

$$[1-(1-P_{\max}^{n})^{m}]^{-1} \le E\lambda \le [1-(1-P_{\min}^{n})^{m}]^{-1} \tag{6}$$

By formula (6) can obtain that if you have a uniform upper and lower bounds of P_{kj}, then the first upper and lower bounds of the range expected convergence time can be determined.

Assuming a polynomial function $P(n)$ on the complexity, if meet $P_{\min} \ge \left[1-\left(1-P(n)^{-1}\right)^{1/m}\right]^{1/n}$, according to equation (6) can be obtained,

$$E\lambda \le P(n) \tag{7}$$

By equation (7), we can draw the following conclusion: For $t=1,2,\cdots,n$ and $i=1,2,\cdots,n$, if P_{kj} is large enough, the time complexity of IGACO algorithm can be reduced to a polynomial function about n.

Experiment of Convergence Speed

Experiment operating system: windows XP SP3, programming environment: Matlab R2009a.

Experimental data:

Data used in the experiment comes from:

TSPlib:http://www.iwr.uni-heidelberg.de/groups/comopt/software/TSPLIB95/tsp/.

Experimental method:

First, specific the probability function[3]:

$$P(i,j,t)=\frac{\eta^{\beta}(i,j)\cdot c^{\alpha}(i,j,t)}{\sum_{k\in D_i}\eta^{\beta}(i,j)\cdot c^{\alpha}(i,j,t)},(i,j)\in D_i \tag{8}$$

Where τ is the pheromone, in TSP, η is the reciprocal of the distance between city i and j. The introduction of heuristic argument η makes greater pheromone of short distance cities. α and β are two parameters. α,η,τ all greater than 0. $c(i,j,t)$ is the time rate of pheromone in path (i,j). Pheromone Concept ratios as follows: ratio of pheromone in path (i,j) is represented on the path of all paths ant pheromones at a node i and may be selected on the ratio.

$$c(i,j,t)=\frac{\tau(i,j,t)}{\sum_{k\in D_i}\tau(i,k,t)},(i,j)\in D_i \tag{9}$$

For IGACO algorithm:

Residual rate of pheromone function[2] [3]:

$$\delta(t)=\frac{\gamma_0 e^{\lambda t_m}}{1+\gamma_0 e^{\lambda t_m}},\gamma_0>0,\lambda>0 \tag{10}$$

Pheromone increment function[2] [3]:

$$\mu(i,j,t)=\frac{A(1-\delta(t))\tau(i,j,t)}{\delta(t)},A>1 \tag{11}$$

Initialization pheromone τ_0=10, α=1, β=5; in formula (10) γ_0=5, λ=0.01; in formula (11) A=1.01.

Experimental results and analysis:

The convergence process of ACO and IGACO in the implementation process is shown as below:

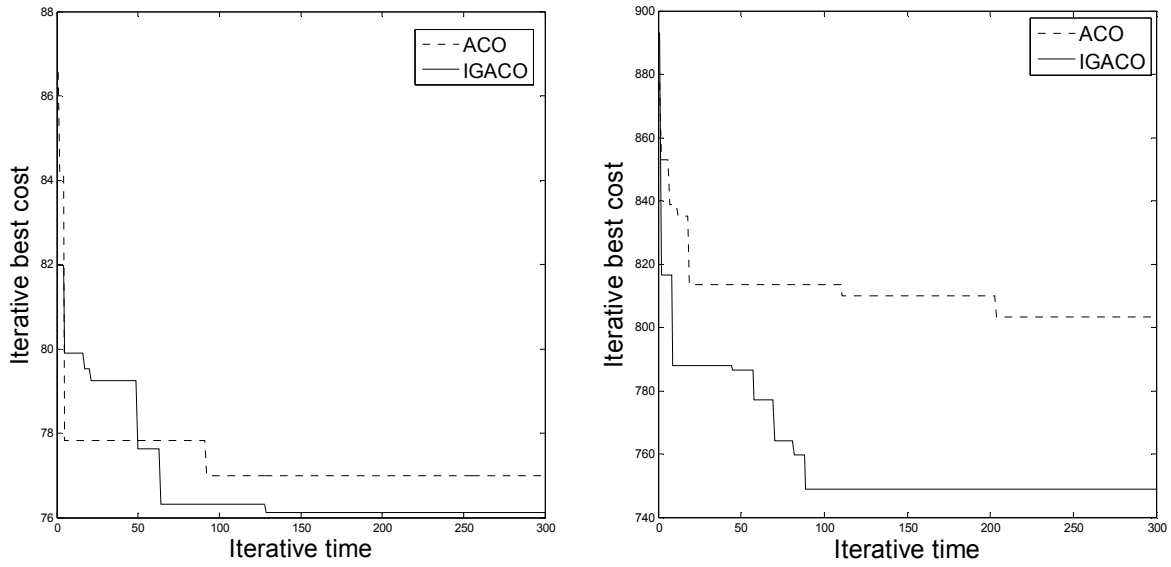

Fig. 1 22 and 70 cities TSP convergence process comparison between ACO and IGACO

In Fig. 1, the left picture is 22 cities TSP convergence process comparison between ACO and IGACO and the right one is 70 cities. The horizontal axis in the figure represents the number of iterations, and the vertical axis represents the distance between the city; the obtained solid line represents the convergence process of IGACO and the dashed line represents the convergence process of traditional ant colony algorithm.

By the experimental results above, we can obtain that the IGACO algorithm always converge to the smaller solution and the convergence speed is better than the traditional ant colony algorithm. Moreover, with the expansion of the city scale, the advantage of IGACO is more and more obvious.

Conclusion

Based on the experimental results, we can see that in a limited number of iterations, IGACO algorithm could get the better solution compare to the traditional ant colony algorithm. The improvement made by IGACO algorithm base on the traditional ant colony algorithm is effective.

Convergence Speed of Multi-objective Generalized Ant Colony Optimization Algorithm

Daiyuan Zhang[a], Peng Fu[b]

College of Computer, Nanjing University of Posts and Telecommunications, Nanjing, Jiangsu 210003, China

[a]email: dyzhang@njupt.edu.cn, [b]email: fupeng2006@126.com

Keywords: Multi-objective; Convergence Speed; Generalized ant colony algorithm

Abstract. Multi-objective optimization problems are very important, but it is hard to optimized or solved. Generalized ant colony optimization (GACO) algorithm is a new kind of ant colony optimization (ACO) algorithm developed in recent years. In this paper, we try to combine Multi-objective optimization problems with GACO algorithm, established a model for multi-objective GACO algorithm by absorbing state Markov chain, and present a method for estimating the convergence speed of multi-objective GACO algorithm. Simulation results show that the convergence speed of multi-objective GACO algorithm is faster than traditional multi-objective ACO algorithm.

Introduction

Ant colony algorithm [1] is a new type of simulated evolutionary algorithm. But it has some disadvantages such as slow convergence, easy to fall into local optimum etc. For a certain improvement, generalized ant colony optimization (GACO) algorithm was proposed in literature [2]. The improved generalized ant colony optimization algorithm [3] further improves the probability selection function from a strictly monotone increasing function to a bounded function and gives a more general expression of the ants in a given source node to select the next node.

Although multi-objective generalized ant colony algorithm has solved some combinatorial optimization problems, there are few theoretical analysis about the convergence speed of multi-objective generalized ant colony algorithm. To solve this problem, we build a strong versatility, absorbing process model based on Markov chain. On the basis of the above, we present a preliminary analysis estimation method of convergence speed for multi-objective GACO algorithm.

The Convergence Speed of Multi-objective GACO Algorithm

In order to analyze the multi-objective GACO algorithm convergence speed, this section will establish the multi-objective GACO algorithm with absorbing state Markov process model [4]. The absorbing Markov chain model of multi-objective GACO algorithm can be presented with the following definitions.

$X(t)\big|_{t=0}^{+\infty}$ is the stochastic process for the multi-objective GACO algorithms, where $X(t)=(S(t),T(t))$, and $S(t)=S_{bs}(t)\cup S_{iter}(t)$, $S_{\mathrm{bs}}(t)$ is the current approximate Pareto optimal solution set on t time. $S_{\mathrm{iter}}(t)$ is the set of complete iteration for Pareto solution obtained by ants. It's state space is Y on t moment [5].

$$P\left\{X(t)\in Y\,\middle|\,X(0),X(1)\cdots X(t-1)\right\}=P\left\{X(t)\in Y\,\middle|\,X(t-1)\right\} \tag{1}$$

$X(t)\big|_{t=0}^{+\infty}$ is an absorbing Markov chain.

Expected convergence time describes the multi-object GACO algorithm for Pareto optimal solution of the desired time for the first time to achieve a global approximation with probability 1. Because the multi-objective GACO algorithm meets the absorbing states of the markov process, our study can use expected convergence time of approximate Pareto optimal solution as the convergence rate of the multi-objective GACO algorithm indicators.

Definition 1 Given a absorbing state markov process $X(t)|_{t=0}^{+\infty}(\forall X(t)\in Y)$ and optimal state space $Y^*\in Y$, if μ is a random variable: when $t=\mu$, $X(t)\in Y^*$,$0\le t<\mu$, $X(t)\notin Y^*$, then we say the expectations of μ. $E\mu$ is headed approximate Pareto optimal solution of the desired time.

Assume that when $t=\mu$, $X(t)\in Y^*$. Because the $X(t)$ is a process of absorbing states Markov, $P\left\{X(\mu+1)\notin Y^*\middle|X(\mu)\in Y^*\right\}=0$ is defined by the Markov process. Because $X(t)\in Y^*$, $t=\mu$, so $P\left\{X(\mu)\in Y^*\right\}=1$. Similarly available, when $t\geqslant\mu, P\left\{X(t)\in Y^*\right\}=1$,when $t<\mu$, $P\left\{X(t)\in Y^*\right\}<1$. $E\mu$ indicates the convergence time that multi-objective GACO algorithm spend in reaching the Pareto optimal solution.

Definition 2 $\lambda(t)=P\left\{X(t)\in Y^*\right\}$ is the probability of the multi-objective GACO algorithm attains the Pareto optimal solution state set at t time. Among them, $\lim_{t\to\infty}\lambda(t)=1$.

This paper analyzes the multi-objective GACO optimization algorithm convergence speed in the continuous-time and it is based on continuous-time Markov process, expected convergence time analysis is as follows:

$$\lambda(t)=\mathrm{P}\left\{X(t)\in Y^*\right\}=P(\mu\le t) \tag{2}$$

$$\Rightarrow P(\mu=t)=P(\mu\le t)-P(\mu\le t-1)=\lambda(t)-\lambda(t-1)$$

$$\begin{aligned}E\mu&=\int_{t=0}^{+\infty}t\cdot P(\mu=t)dt\\&=\int_{t=0}^{+\infty}t\cdot\left(\lambda(t)-\lambda(t-1)\right)dt\\&=\int_{i=0}^{+\infty}\int_{t=i}^{+\infty}\left(\lambda(t)-\lambda(t-1)\right)dtdi\\&=\int_{i=0}^{+\infty}\left[\lim_{t\to+\infty}\lambda(t)-\lambda(i)\right]di\\&=\int_{i=0}^{+\infty}\left(1-\lambda(i)\right)di\end{aligned} \tag{3}$$

Assume that $a\le\mathrm{P}\left\{X(t)\in Y^*\middle|X(t-1)\notin Y^*\right\}\le b$, According to the formula of full probability，

$$\begin{aligned}\lambda(t)&=[1-\lambda(t-1)]P\{X(t)\in Y^*\middle|X(t-1)\notin Y^*\}+\lambda(t-1)P\{X(t)\in Y^*\middle|X(t-1)\notin Y^*\}\\&=[1-\lambda(t-1)]P\{X(t)\in Y^*\middle|X(t-1)\notin Y^*\}+\lambda(t-1)\end{aligned} \tag{4}$$

$$\begin{aligned}E\mu&=\int_{t=0}^{+\infty}(1-\lambda(i))dt\le\int_{t=0}^{+\infty}(1-\lambda(0))\prod_{i=1}^{+\infty}(1-P(i))dt\\&=[1-\lambda(0)]\sum_{i=1}^{+\infty}(1-a)^i=a^{-1}[1-\lambda(0)]\end{aligned} \tag{5}$$

Similarly available: $E\mu=\int_{t=0}^{+\infty}(1-\lambda(i))dt\ge b^{-1}[1-\lambda(0)]$

Assuming there are n nodes in an iterative cycle. If Pareto optimal solution is obtained in the k-th iteration cycle, it's sequence of nodes is: $r(t),c_{k1},c_{k2},\cdot,c_{kn},d(t)$. The probability that Pareto optimal solution is attained at the k-th iteration time can be calculated according to the following: [3]:

$$P(r(t),c_{k1}(t),c_{k2}(t),\cdot\cdot c_{kn}(t),d(t))=\prod_{j=1}^{n+1}P_{kj} \tag{6}$$

Each P_{kj} is calculated by the probability selection function. Suppose there are m ants in multi-objective GACO algorithm, then the probability of Pareto optimal solutions found in the k-th iteration as follows:

$$P_t = P\left\{X(t)\in Y^* \,\middle|\, X(t-1)\notin Y^*\right\} = 1-\left(1-P\left(s^*\right)\right)^m = 1-\prod_{k=1}^{m}\left(1-\prod_{j=1}^{n+1}P_{kj}\right) \tag{7}$$

When $0 < p_{\min} \le P_{kj} \le p_{\max}, k = 1,2\cdots m,\ j = 1,2\cdots n$, because in the initialization process, $S(t) = S_{bs}(t) \cup S_{iter}(t) = \varnothing$, so $\lambda(0) = 0$. According to equation (4) and (5), multi-objective GACO algorithm expectation convergence time becomes as follows:

$$\frac{1}{1-(1-p^n{}_{\max})^m} \le E\mu \le \frac{1}{1-(1-p^n{}_{\min})^m} \tag{8}$$

The formula (8) indicates that the upper bound and lower bound of the expected convergence time can be confirmed, if the crucial probability has unified upper bound and unified lower bound.

Simulation Results

Experiment operating system is Windows 7, programming tool is MATLAB R2009a. Data from constructed as a multi-objective TSP data and its contents are as follows:

$$D_1 = \begin{bmatrix}
0 & 10 & 15 & 78 & 93 & 79 & 48 & 49 & 76 & 11 & 81 & 72 & 55 & 81 & 3 \\

3 & 40 & 21 & 25 & 93 & 93 & 48 & 28 & 88 & 41 & 67 & 76 & 72 & 98 & 0
\end{bmatrix}$$

$$D_2 = \begin{bmatrix}
0 & 20 & 65 & 88 & 13 & 89 & 38 & 29 & 16 & 21 & 82 & 14 & 14 & 43 & 47 \\
20 & 0 & 57 & 36 & 54 & 76 & 27 & 18 & 39 & 45 & 82 & 61 & 76 & 29 & 47 \\
65 & 57 & 0 & 69 & 19 & 51 & 23 & 14 & 90 & 74 & 14 & 61 & 29 & 31 & 51 \\
88 & 36 & 69 & 0 & 24 & 39 & 18 & 45 & 18 & 81 & 14 & 76 & 29 & 78 & 67 \\
13 & 54 & 19 & 24 & 0 & 64 & 73 & 34 & 57 & 58 & 43 & 29 & 31 & 78 & 28 \\
89 & 76 & 52 & 39 & 64 & 0 & 32 & 88 & 75 & 18 & 47 & 47 & 51 & 67 & 28 \\
38 & 27 & 23 & 18 & 73 & 32 & 0 & 74 & 15 & 12 & 48 & 82 & 83 & 80 & 90 \\
29 & 18 & 14 & 45 & 34 & 88 & 74 & 0 & 68 & 35 & 23 & 45 & 65 & 43 & 42 \\
16 & 39 & 90 & 18 & 57 & 75 & 15 & 68 & 0 & 57 & 34 & 35 & 48 & 56 & 49 \\
21 & 45 & 74 & 81 & 58 & 18 & 12 & 35 & 57 & 0 & 34 & 37 & 78 & 68 & 56 \\
82 & 82 & 14 & 14 & 43 & 47 & 48 & 23 & 34 & 34 & 0 & 32 & 19 & 34 & 45 \\
14 & 61 & 61 & 76 & 29 & 47 & 82 & 45 & 35 & 37 & 32 & 0 & 27 & 20 & 37 \\
14 & 76 & 29 & 29 & 31 & 51 & 83 & 65 & 48 & 78 & 19 & 27 & 0 & 65 & 45 \\
43 & 29 & 31 & 78 & 78 & 67 & 80 & 43 & 56 & 68 & 34 & 20 & 65 & 0 & 12 \\
47 & 47 & 51 & 57 & 28 & 28 & 90 & 42 & 49 & 56 & 45 & 37 & 45 & 12 & 0
\end{bmatrix}$$

D_1 and D_2 are the generation of value matrix corresponding to the two objectives between various cities. Multi-objective GACO algorithm's probability selection function $P(i,j,t)$ as follows:

$$P(i,j,t) = \frac{\eta^{\log(\beta)}(i,j)\cdot\tau^{\log(\alpha)}(i,j,t)}{\sum_{k\in D_i}\eta^{\log(\beta)}(i,k)\cdot\tau^{\log(\alpha)}(i,k,t)}, (i,j)\in D_i \tag{9}$$

The formula (9) conforms to the definition of state transition probability in literature [3]. For multi-object GACO algorithm:

$$\tau(i,j,t) = w(1)\tau^1(i,j,t) + w(2)\tau^2(i,j,t) \tag{10}$$

$$\eta(i,j) = \frac{1}{w(1)\cdot d(1)_{i,j} + w(2)\cdot d(2)_{i,j}} \tag{11}$$

α and β are two parameters. $d(1)_{i,j}, d(2)_{i,j}$ indicates the substituting value of 2 different objectives between the (i, j). $w(1), w(2)$ indicates weighting factor. Residual rate of pheromone function and pheromone increment function [3] are defined as follow:

$$\delta(t) = \frac{\gamma_0 e^{\lambda t}}{1+\gamma_0 e^{\lambda t}} \tag{12}$$

Where, λ is a positive constant, $\gamma_0 = \delta_0/1-\delta_0$

$$\mu(t) = \frac{A\left(1-\delta(t)\right)\tau(i,j,t)}{\delta(t)} \tag{13}$$

Where, A is a positive constant.

Initializing pheromone $\tau_1=\tau_2=10$, $\alpha=3$, $\beta=6$. In formula (12)(13) $\gamma_0=5$, $\lambda=0.01$, $A=1.01$[3]. Pheromone evaporation parameter $\rho=0.65$, weighting factor $w(1)=w(2)=0.5$.

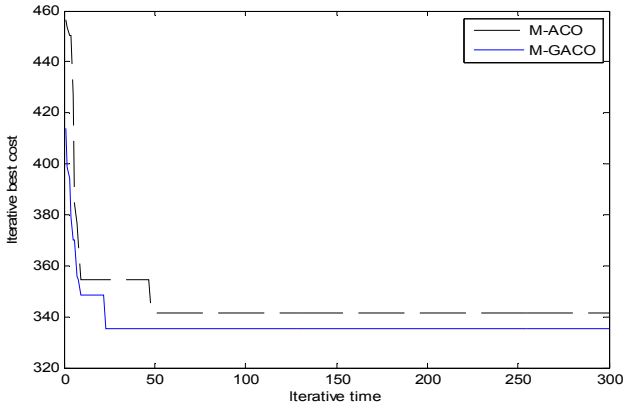

Figure 1 Convergence speed comparison

In Figure 1, abscissa axis represents the number of iterations, the vertical axis represents the length of path which the ants find, dotted line part is the convergence process of traditional multi-objective ant colony algorithm, solid line is the convergence process of multi-objective GACO algorithm. Integrated on, convergence speed of multi-objective GACO algorithm is faster than the traditional multi-objective ant colony algorithm.

Conclusion

In this paper, based on the process model of Markov chain, we put the expected convergence time as an important index of convergence speed, analysis the convergence speed of multi-objective GACO algorithm exploringly and give the change interval of convergence speed. Simulation results show that multi-objective GACO algorithm convergence speed is faster than the traditional multi-objective ant colony algorithm.

Keywords: Attributes-importanc, Rough Set, weight

Abstract. This paper puts forward on the Rough Set theory algorithms, and combined it with the method of determining the index weights, then established a weight determined algorithm model based on rough set, Thereby reducing the influence of subjective factors on the weight determination.

Introduction

Rough set theory is a mathematical theory to deal with imprecise, incomplete and inconsistent information. This theory while maintaining the original decision table without changing the classification ability, through knowledge reduction, value reduction, export classification decision tables and decision rules. It is a mathematical tools to deal with the information and knowledge use the way of quantitative analysis to process the data of imprecise, inconsistent, incomplete. The initial prototype of Rough set theory is from the model of relatively simple information. Rough set method has been successfully applied to many fields such as medicine, management, finance, image processing and decision analysis.

We should follow the following principles to determine the index weight: System optimization principles and the principles of the evaluator's subjective intent with a combination of objective circumstances [1]. The traditional evaluation process methods are affected by subjective factors, this means that there will be some deviation with the evaluation results obtained more or less. In this paper we use attribute importance of rough set theory combined with expert scoring method to determine the weight of each evaluation item, thereby reducing the influence of subjective factors on the weights.

The Knowledge of Rough Set

In the research area of Rough Set, the ability to objectively classify things in rough sets is called knowledge. The object is a set of some objects that consists of a collection of multi-valued attribute, for each object and its properties, there will be a value as a symbol to description it, object properties and symbol descriptors are the basic elements to expression the decision problem. Typically, the available information about the object is not necessarily enough to divide its membership categories. This imprecision cause the object are indistinguishability. It can be used to decision and planning the form of the set, to represents the important relationship between the most important properties and specific categories.

2.1 The indistinguishable relationship

Set up a information system $S=<U,A,V,F>$, U is a non-empty and limited individual set (called it the discourse domain). A is a non-empty and limited attribute set,and $A=CYD$, $\forall_C \in A$, $C:U \to V_{CC}$ Is a mapping, then $\forall_U \in U$, $C_{(U)} \in V_c$ so V_c is a subset for C,so $V=YV_C$ is a subset for A. We definitions $IND(C)$ is a indistinguishable relationship for U to attribute C ,and $x,y \in U$, x,y is equivalence to C ,then there wil be $V_a \in C,(x,y) \in IND(C)$ .only if $f_{(x,a)}=f_{(y,a)}$,that mean $IND(C)=\{(x,y) \in U \times U : \forall_A \in C \wedge a(x)=a(y)\}$ is a equivalence relation.

2.2 knowledge dependence

$a_R(X)$ is the roughness for the degree of uncertainty of the sample subset X ,and the roughness is defined as: $a_R(X)=\frac{Card(R_(X))}{Card(R^-(X))}$, $Card$ is the cardinal number for the set(The number of elements in the set).When $0 \le a_R(X) \le 1$ if $a_R(X)=1$,then we can define X is determined by R ;and X is Totally dependent on R;if $0 < a_R(X) < 1$,then X is Ragged for R;$a_R(X)$ is Approach the Accuracy of X ,this we defined X is Rough dependence on R ;

When $a_R(X)=0$,then X and R are both completely independent. $a_R(X)$ is the dependence coefficient for X and R .

2.3 The importance of property

In the decision table, different properties may have different importance. To find out the importance of certain attributes (or the attributes set), the general approach is to remove some attributes from the table. If the change is larger, then we can say these attributes are important, On the contrary, the importance of the attributes are lower. C is the Condition attribute set, D is the Decision attribute set, the importance for the attributes subset C' to D is: $\sigma_{CD}(C')=\gamma_C(D)-\gamma_{C-C'}(D)$.

Data preprocessing

For the attribute set C , we can get the importance of the classification for attributes subset $B' \subseteq B$, then get the both dependence $r_B(C)-r_{B-B'}(C)$. is mean we classified the object, to remove some attributes subset B' from set B , then we can get the Influence.Fig 1 shows us the knowledge representation system.

U	a	b	c	d	e
1	1	1	0	1	0
2	0	0	0	1	0
3	0	0	0	0	1
4	0	1	0	1	1
5	1	1	0	0	1

Fig 1 A knowledge representation system

The discourse domain num from1 to 5 , and the condition attribute set $C=\{a,b,c,d\}$, decision attribute set $D=\{e\}$. $U/ind(a,b,c,d)=\{\{1\},\{2\},\{3\},\{4\},\{5\}\}$, $U/ind(e)=\{\{1,2\}\{3,4,5\}\}$, $POS_c(D)=\{1,2,3,4,5\}$, $r_c(D)=Card(POS_C(D))/Card(U)=5/5=1$,now we removed property a ,get $U/ind(b,c,d)=\{\{1,4\},\{2\},\{3\},\{5\}\}$, $POS_{C-a}(D)=\{2,3,5\}$, $r_{C-a}(D)=3/5=0.6$. removed property b ,get $U/ind(a,c,d)=\{\{1\},\{3\},\{2,4\}\{5\}\}$ $POS_{C-b}(D)=\{1,3,5\}$, $r_{C-a}(D)=3/5=0.6$. removed property c ,get $U/ind(a,b,d)=\{\{1\},\{2\}\{3\},\{4\},\{5\}\}$, $POS_{C-c}(D)=\{1,2,3,4,5\}$, $r_{C-c}(D)=5/5=1$. At last we removed property d , $U/ind(a,b,c)=\{\{1,5\},\{2,3\},\{4\}\}$, $POS_{C-d}(D)=\{4\}$, $r_{C-d}(D)=1/5=0.2$. Then we can see property d is most important. Property a and b followed by d .And c is the redundant attributes.

Weight determination method based on Rough Set Theory

In different decision-making environment, the same properties have different effects on decision-making output. That the weights have different sensitivity on the environmental.In the Rough set theory, attribute importance reflects of the impact on the current data on the environmental attributes decision. But it does not reflect a priori knowledge of decision makers.In this paper we combined the attribute importance of the rough set theory with the property rights which are determined by the priori knowledge,and then to determine the final comprehensive weight. In order to achieve the subjective priori knowledge to be the same as Objective circumstances

Now we assume that the condition attributes in the system is C , the decision attribute is D . C has much different propertys,the num is n ,they are $a_1, a_2, ..., a_n$, the priori knowledge given by the decision maker weights were $p(a_1), p(a_2), ..., p(a_n)$. The Specific implementation methods are followed:

Input: The evaluation results of each item evaluated projects in the knowledge representation system, to get each item weight from expert scoring method.

Output: Right weight for each item

Steps:

Step1: Division the equivalence classes: $U/C, U/D, U/(C-\{c_i\})$,get $posC(D), posC-\{c_i\}(D), i=1,2,...m;$

Step 2 :we get the Dependence: $a_R(X) = r_C(D) = |POS_C(D)| / |U|$,from $a_R(X) = \frac{Card(R_-(X))}{Card(R^-(X))}$,then we can get each dependence $k_{C-\{c_i\}} = r_{C-\{c_i\}}(D) = |POS_{C-\{c_i\}}(D)| / |U|$, $i = 1,2,...,m$;

Step 3 : from $\sigma_{CD}(C) = \gamma_C(D) - \gamma_{C-C}(D)$,we can get the importance of C_i , $\sigma_{CD}(\{c_i\}) = \gamma_C(D) - \gamma_{C-\{c_i\}}(D)$;

Step 4 : normalized the importance of each attribute, $I_i = \frac{\sigma_{CD}(\{c_i\})}{\sum_i^m \sigma_{CD}(\{c_i\})} = \frac{r_C(D) - r_{C-i}(D)}{\sum_{i=1}^n r_C(D) - r_{C-i}(D)}$, $i = 1,2,...,m$.

Step 5:Here is the item weight got from Rough set method, we call it Objective weights, correspondingly, P_i is the right weight got from Expert scoring method is called Subjective weights.

Final weight of each evaluation term weight calculated by the following formula $R_i = \lambda P_i + (1-\lambda) I_i (0 \le \lambda \le 1)$, $i = 1,2,...,m$. Now the bias of P_i and I_i are determined by λ .

Make Table 1 as an example, Assumed $\lambda = 0.4$, the right weight of each attribute were given by experts: $p_{(a)} = 0.3, p_{(b)} = 0.2, p_{(c)} = 0.1, p_{(d)} = 0.4$,then from the results of attribute importance,we can get $r_C(D) - r_{C-a}(D) = 1 - 0.6 = 0.4$; $r_C(D) - r_{C-b}(D) = 1 - 0.6 = 0.4$; $r_C(D) - r_{C-c}(D) = 1 - 1 = 0$; $r_C(D) - r_{C-d}(D) = 1 - 0.2 = 0.8$; so the objective weight of each attribute weights are $I_{(a)} = \frac{0.4}{0.4+0.4+0+0.8} = 0.25$, $I_{(b)} = \frac{0.4}{0.4+0.4+0+0.8} = 0.25$, $I_{(c)} = \frac{0}{0.4+0.4+0+0.8} = 0$, $I_{(d)} = \frac{0.8}{0.4+0.4+0+0.8} = 0.5$ .then the Comprehensive weight of each attribute are: $R_{(a)} = 0.6 \times 0.25 + 0.4 \times 0.3 = 0.27$, $R_{(b)} = 0.6 \times 0.25 + 0.4 \times 0.2 = 0.23$, $R_{(c)} = 0.6 \times 0 + 0.4 \times 0.1 = 0.04$, $R_{(d)} = 0.6 \times 0.5 + 0.4 \times 0.4 = 0.46$. Thus, we get the comprehensive weight of each attribute which are combination subjective with objective.

Conclusion

There is a malady in most of the evaluation process to determine the index weight, which is affected by the decision makers' subjective experience. The rough set theory to determine the importance of property is a manifestation the objective existence relative importance (which is objective existence) of large amount of historical data for each attribute. Therefore, combined the attributes importance theory of the rough set theory with expert scoring method, Would be a reasonable solution.

Keywords: electronic flight bag (EFB); takeoff performance; interpolation; iOS

Abstract. The Electronic Flight Bag (EFB) provides pilots real-time or existing data by converting the papery documents into electronic books. Consequently the efficiency and the security have been improved, which reduce pilots' ground communication time and the paperweight. As a key factor of what influences the takeoff process, the takeoff performance undoubtedly has been an essential research task of EFB, while many factors may affect the takeoff performance, such as flap position, anti-ice and the external temperature. By means of interpolation, this paper integrates those factors and gets Maximum Take-off Weight (TOW), Take-off Decision Speed (V1), Take-off Rotation Speed (VR) and Take-off Safety Speed (V2). And then implants the result into the EFB based on the iOS.

Introduction

Throughout the whole flight activity, the takeoff stage only account a small part, while the accident rate goes as high as 16%. The reason is that amounts of factors can influence takeoff performance, causing complexity of the takeoff stage. And the takeoff performance determines the maximum allowable takeoff weight of the aircraft, which directly affects the maximum payload, thus affecting the economy of aircraft operations.

The purpose of the takeoff performance calculation and analysis is to ensure the safety and improve the economy of takeoff, mainly based on the content of the various restrictions and calculates related factors to determine the maximum allowable takeoff weight for specific aircraft models, then check the actual takeoff weight to determine the takeoff thrust, and work out the major takeoff speed, especially the V1 takeoff decision speed, VR takeoff rotation speed and V2 takeoff safety speed, in order to ensure the flight safety and achieve the expected takeoff performance.

Relative technologies

The mobile terminal technology refers to the technology, which used in a mobile communication equipment, to terminate wireless transmission from or to the network, and adapt the capability of terminal device to a wireless transmission part.

Electronic Flight Bag (EFB) refers to the hardware and software supporting certain features, is located in the cockpit display system. Electronic flight bag includes a variety of air data information and the various basic calculations (such as performance calculation, fuel calculation etc.), some of these functions is accomplished with the use of traditional paper referenced materials or data provided by airlines "flight dispatcher" to flight crew. Functional range of electronic flight bag includes a variety of application programs and the database, the display of information can be achieved through plenty of techniques, formats and communication forms.

Algorithm Design

According to the mathematical model of the algorithm, the algorithm can be shown in the flowchart in Figure 1:

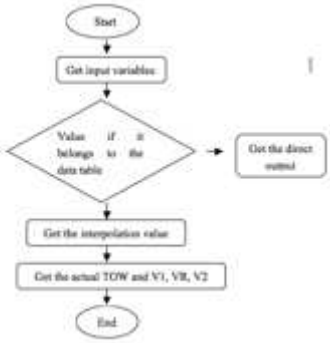

Figure 1Algorithm Flowchart

This algorithm is a highlight in combination with the thought of Manchester encoding array operations, which greatly simplify the calculation process and improve the speed. Input value Z, X, I, J, K, L, Y and W, correspond to Airport Runway ID, Runway state, QNH (hPa), OAT (℃), Wind (KT), Weight (kg), Flap setting and Anti - ice in the data table. Creating ADO database connection for query operations data, query whether there is a corresponding record in the database. That means query whether there is a record with value Z, X, I, J, K, L, Y and W equaling to the input values, if any, then outputs comparable TOW, V1, VR and V2 values, corresponding to TOW (LBS), V1 (KT), VR (KT) and V2 (KT) in the data table; If does not present, interpolates I, J, K, L to get the corresponding output values.

Crucial Technology

For a directed acyclic graph (DAG) Topological sorting is to arrange all vertices of G in a linear sequence, then for any pair of vertices U and V in the figure, if it belongs to the E (G), U in the linear sequence occurs before V. Usually, the linear sequence is known as satisfied topological order sequences, topological sequences for short. In simple terms, getting a total order by a partial order of a set is called topological sorting. The definition of partial order and total order in Discrete Mathematics are as follows:

If R is a collection on X set, and the R is reflexive, anti-symmetric and transitive, then R is called partial ordering relations on X set. Let R be a partial order on X set, if for every x, y belongs to the X must be xRy or yRx, then R is called total ordering relations on X set. Simply put, partial order refers to comparisons between some elements in the set, while total order refers to comparisons among all elements in the set.

Manchester Encoding is also called phase encoding (PE). It is a synchronous clock encoding technology used to code the clock and data of a synchronous bit stream in physical layer. Manchester encoding is used in the Ethernet media system and provides a simple way to encode binary sequence without a long period and level conversion, thus preventing the loss of clock synchronization or the analog link bit error of poor compensation from the low-frequency displacement. In Manchester encoding, phases differ voltage jump to distinguish 1 and 0 that means voltage jump for 1 and the negative voltage jump for 0. Therefore, this encoding is also known as the phase encoding. Because

the jump occurred in the middle of each symbol, the receiver can easily use it as a synchronous clock, so the encoding is also called self-synchronizing encoding.

This algorithm combined with the mathematical thought of topological graph theory, transforming the interpolation process into a graph matrix and then use the Manchester encoding to realize the interpolation process, which makes the algorithm more clear.

The specific code and flow chart are shown in figure 2. In matrix M, 0 and 1 corresponding to the smaller and larger value in the data table of value I, J, K, L. For value I, 0 and 1 correspond to different I interpolation, similar to J, K, and L. This is the combining method of algorithm with Manchester encoding. And each time the results are interpolated from the previous interpolation result, which demonstrates the combination of the algorithm and graph theory.

Interpolation algorithm formula is as follows:

In which X represents the results for TOW, V1, VR, and V2. X1 and X0 is the previous result or queried results on the data table. A0 and A1 corresponding to smaller and larger value of value I, J, K, L, while A is the actual I, J, K, L value.

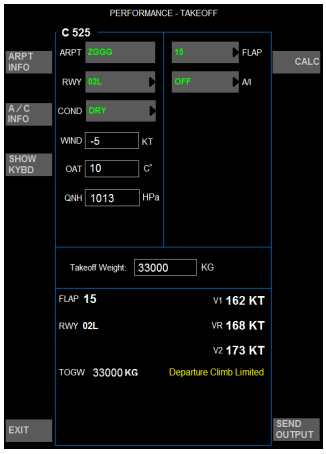
Interfaces and Interface Design

This algorithm selects iOS interface. And the electronic flight bag based on iOS has been used in cockpits, such as the iPad for pilots in cockpits.

The advantages of iOS interface: iOS system is highly integrate into hardware, which greatly reduce the differentiation and ensure the algorithm operates steadily, meantime the gorgeous interface and usability of iOS system facilitate the convenience of the pilot. What's more, the data security is one of the advantages; since the strong data protection of iOS can guarantee the security of data, then ensure the safety of flight.

The defects of iOS interface: iOS interface also has shortcomings. In the latest iOS7 system, there are some defects about AutoCorrect appeared, which will influence pilots' use of EFB, further affecting the user experience of our takeoff performance algorithm.

This algorithm finally choose iOS interface to bring electronic flight bag users to acme, and the iOS handset operating system can help us achieve this requirement.



The human factor is an important aspect to affect the flight safety. When deal with something about the electronic flight bag and man-machine interface, this algorithm designs strictly in accordance with the basic principles of human factors to getting an intuitive user interface and designs data input or some other options according to the "agency regulations", maintaining coordination with other designs in the electronic flight bag to avoid affecting the use of other functions.

Implants the algorithm into iOS based EFB will get a interface as figure 2: Figure 2 EFB

Conclusions

After careful test and arrangement, the algorithm is now applied into iOS operating system for mobile devices and gets some achievements, also affects well in the terms of usability and user experience and has applied for national patent.

Keywords: Quantization, Machine Learning, Region Analogy

Abstract. Data quantization methods for numerical attributes play an extremely important role in handy talents statistics assessment and technology learning because discrete values of attributes are required in most classification methods. In this paper, we present an region analogy-based quantization method for numerical data. It expresses an inner coherence criterion which is thought to be as a new criterion in the ways of quantization. In addition, a heuristic quantization algorithm is proposed to achieve a satisfying quantization result with the aim to improve the performance of inductive learning algorithms. They realize criterion as well as quantifying the true value attributions exactly and reasonably. Strict experiments on UCI reflects data sets express that our supposed algorithm produces a superior quantization scheme that promotes the classification right of inductive learning than emerging quantization algorithms.

Introduction

Data mining is a wide range of technology integration in several areas, containing artificial intelligence, inductive learning and task mining, artificial smart. We have been a lot of roots in these areas of data mining algorithms. Data quantization is the processing techniques commonly used data mining, machine learning and knowledge invention [1,2]. Many real-world data mining tasks conclude enormous attributions. Nevertheless, almost all of data mining techniques can not deal with such attributions. Therefore, it is necessary and important to partition into several time regions to produce a small number of different values from some features and numerical feature domain value. A perfect quantization can not only produce a concise summarization of numerical attributions to do a favors to the people cover more about the data more convenient, but also lead to quick and accurate learning [3].

Existing quantization techniques can be grouped into top to bottom vs. bottom to top, however top-down can be further classified into unsupervised vs. supervised [4].Top to bottom methods begin with primary moment and slice it to tiny time points, whereas bottom to top techniques start from someone value region sets and iteratively merge the region pair. Unsupervised algorithms do not consider information class, i.e., EQW and EQF [4]. While, supervised algorithms consider information class with different feature, i.e., the quantization algorithms [5,6] based on Chi2, class-feature interdependency-based methods like CACC [7], OCDD [8], and entropy-based discretion [9], and so on.

In this paper, we pay attention to bottom-up quantization methods and propose a region analogy-based quantization method for numerical data. The main contributions of this paper are summarized as follows:

1) We define a region analogy-based criterion which is thought to be as a new merging criterion in the way of quantization.
2) We propose a heuristic quantization algorithm to achieve a satisfying quantization result with the aim to improve the performance of inductive learning algorithms. The proposed algorithm realizes fair standard and quantifying numeric value features reasonably and exactly.
3) We conduct the empirical tests on UCI data sets, and indicate that the supposed method yields a superior quantization schedule that enhances the classification precise of inductive learning than being algorithms.

Our Quantization Method

In this section, we propose a method based on analogy quantization region numerical data. Details before into our approach, we first declare to quantify the problem. Quantitative tasks require samples, each sample belongs to a class has only one training data. Next, the existence of quantitative solution, quantitative, numerical time region within the scope of the attributes of digital domain:

$$P:\{[t_0,t_1],[t_1,t_2],\cdots,[t_{I-1},t_I]\} \tag{1}$$

Where t_0 is the smallest value and t_I is the largest value of a numerical attribute. The values in P are classified in ascending order. For quantization goal, complete data are pointed on target attribute. This projection consequence is 2D *table graph,* see Table 1, having S *amount*s and I rows. Each row acts according to a primary data region, and each column reacts to another class. N_{ij} reflects instance number in j th class belong to i region T_i. $N_{\cdot j}$ is the overall instance number in the j th level. $N_{i\cdot}$ is the overall number of models that are within the time region T_i.

Table1 Table information

Regions	C_{lable}				Row Sum
	C_1	C_2	…	C_S	
$T_1:[t_0,t_1]$	N_{11}	N_{12}	…	N_{1S}	$N_{1\cdot}$
$T_2:[t_1,t_2]$	N_{21}	N_{22}	…	N_{2S}	$N_{2\cdot}$
…	…	…	…	…	…
$T_I:[t_{I-1},t_I]$	N_{I1}	N_{I2}	…	N_{IS}	$N_{i\cdot}$
Sum of Column	$N_{\cdot 1}$	$N_{\cdot 2}$	…	$N_{\cdot S}$	N *(total)*

Region analogy criterion

Approximate reasoning is an important research component in the field of artificial intelligence. It needs different analogy measure between images and objects. Analogy between two objects is value-measure of similar degree between two objects. Thus, the more similar are two objects, the higher is their similar degree. Usually, similar degree is un-minus and the value often is between 0 (dissimilar) and 1 (completely similar). The same principle, difference between two objects is value--measure of difference degree between two objects. The more similar are two objects, the lower is their difference. Often, if the value of similar degree between two objects does not change in [0,1], we may use some kind of function to normalize it to [0,1]. It has produced definition and characteristic of the general analogy:

Def. 1 It is known that database B have two arrays t_i and t_j, their similar degree $RAC(t_i,t_j)$ is a mapping from $B\times B$ to the region [0,1]. Therefore, $RAC(t_i,t_j)\in[0,1]$.

A qualified similar criterion or method has the following feature:

$\forall t_i\in B,\quad RAC(t_i,t_i)=1$;

$\forall t_i,t_j\in B$, if t_i and t_j is not same, then $RAC(t_i,t_j)=0$;

$\forall t_i,t_j,t_k\in B$, compared with t_j, if t_k closes to t_i, then $RAC(t_i,t_j)<RAC(t_i,t_k)$

Traditional analogy measure commonly used research results directly. In this paper, we propose a comprehensive significance quantization standard; that is, a new region analogy function which not only can realizes fair and quantifying the real value attributions exactly and reasonably. Definition and analysis of region analogy are as follows.

Def. 2 Give 2 objects; a_i and b_j are a level label to *ith* domain in time first region. Then, the difference between a_i and b_j is:

$$d_{ij} = \begin{cases} 0 & if \ a_i = b_j \\ 1 & if \ a_i \neq b_j \end{cases} \tag{2}$$

Where $i = 1,2,\cdots,s$, $j = 1,2,\cdots,t$, s is the component number of the first region, t is the component number in the second region.

Def. 3 Regarding any adjacent two regions a and b. Region analogy function may be defined as follows:

$$RAC(t_k, t_{k+1}) = 1 - arcsin \frac{\sum_{i=1}^{s}\sum_{j=1}^{t} d_{ij}}{s+t} \tag{3}$$

Based on the above, we design an algorithm that is heuristic in nature. The objective of this algorithm is to find better quantization scheme. The detailed steps can be described as follows.

Step *one*: Compute the level of consistency by [5];

Step *two*: The analogy values calculated for each attribute ascending sort data RAC for an region pair by (3);

Step *three*: Merging;

```
While (∃region pair)
{   Find the point cut, having the largest analogy, and then merge;
    If (some maximal values)
   {    Merging region pair with minimal class number;
        If (level of consistency is changed)
     {  With back merge;
         Quit processing;  }
        Else {Cut; Run Step two;}
     }
    If (many maximal values and same class number between region pairs)
     {  Merging region pair with minimal class number;
         If (level of consistency is changed)
        {  With back merge;
            Quit processing; }
         Else { Cut; Run Step two; }
        }
 }
```

Experimental results

To estimate this algorithm, choose four data sets from the data at the University of California, Irvine repository with digital functions and different size of the data. Data consistency or not correct (not consistent rate to zero), and the data contains information from the previous in real life have been used for medical and scientific research. A summary of data sets can be found in Table 2.

Table 2 Data sets

Data sets	Continuous features Number	Discrete features Number	Class Number	Samples
Auto	5	2	3	392
Iris	4	0	3	150
Breast	9	0	3	683
Ionosphere	34	0	2	351

We compare our proposed region analogy-based method with the following algorithms for result evaluation: C4.5 [2], Mod-chi2 [5], Ext-Chi2 [6], and Unsupervised [4]. Repeating many times experiments and the average prediction accuracy of prediction accuracy is for the final. The five learning precision, listed in Table 3. Comparison results in Table 3 show that on average, our approach to achieve the highest classification accuracy, this shows that our method can produce high quality of the quantization scheme.

Table 3 Learning accuracy (percent) of C4.5 decision tree classification

Data sets	Methods				
	C4.5	Modified Chi2	Extended Chi2	Region analogy-based	Unsupervised
Auto	77.84	80.65	81.42	85.64	72.55
Iris	94.3	94.45	94.45	95.78	92.67
Breast	94.68	96.37	96.37	97.4	93.83
Ionosphere	90.71	93.73	93.91	94.93	84.6

Conclusions

We propose a static, incremental, supervise and bottom-up quantization algorithm, this paper proposed a new quantitative criteria and heuristic algorithm. Classification algorithm to estimate the effect of quantitative plan performance, existing quantization algorithm empirical estimation in the UCI data show that the novel method to create a good quantization criterion.

Keywords: ANT algorithm, anti-ship cruise missile, route planning

Abstract. Anti-ship cruise missile (ASCM) attack route meets the needs of the attack mission will determine the effect of the subsequent attacks. According to research planning of anti-ship cruise missile route based on improved ANT algorithm by elitist strategy. The first is sensitive factor analysis of route planning based on operational requirements. Second is established an objective function and constraints set of route planning, achieved anti-ship cruise missile route planning model. Finally, based on specific objectives, situation and the user's strategies, it can use improved ANT algorithm to plan anti-ship cruise route.

Introduction

The goal of anti-ship cruise missile (ASCM) route planning is to design a flight route to obtain the greatest possible attack effect. Missile flight route from the launch point to the target need to meet a series of route constraints, such as performance of missile, angle of attack and threatening region. Therefore, ASCM route planning can be classified as a large-scale combinatorial optimization problem. The length of time consumed in route planning has a significant impact on the route execution, so ASCM route planning problems have distinct time-sensitive.

ANT algorithm is a heuristic bionic algorithm derived from the biosphere. All ants cooperate to carry out the search for optimized path. So ANT algorithm can exactly solve a large-scale combinatorial optimization problem, such as ASCM route planning. And to a certain extent, there is a slow convergence of ANT algorithm flaw. It is difficult to meet the requirements of ASCM route planning. So we improved ANT algorithm based on elitist strategy introduced by transfer direction inducing factor. In the route planning process, we can accord to the target, threats and current location, immediate to establish new transfer direction inducing factors, enhanced the directionality of path selection of ant, and improved the efficiency of ASCM route planning.

Basic concept

ANT algorithm

In addition to ANT algorithm use positive feedback, through artificial ants also introduces visual function. At time t, the probability of ant k is transferred from node i to j can be written as Eq. 1:

$$P_{ij}^{k}=\begin{cases}\left(\tau_{ij}^{\alpha}(t)\eta_{ij}^{\beta}(t)\right)\Big/\sum_{s\in allowd_k}\tau_{is}^{\alpha}(t)\eta_{is}^{\beta}(t), & if \quad j\in allowd_k\\ 0, & other\end{cases} \tag{1}$$

Which, List $tabu_k$ record the node current ants walked. α is information heuristic factor, which means that the relative importance of the path. β is expected heuristic factor, which means that the relative importance of visibility. η_{ij} (t) is a heuristic function. After each ant access to all nodes, to undermine the old residual information processing can be written as Eq. 2:

$$\tau_{ij}(t+n)=(1-\rho)\tau_{ij}(t)+\Delta\tau_{ij}(t)\qquad \Delta\tau_{ij}(t)=\sum_{k=1}^{m}\Delta\tau_{ij}^{k}(t) \tag{2}$$

ANT algorithm based on transfer direction inducing factor

By the 1) shows that ants move from node i to node j mainly affected by the pheromone, heuristic function, information heuristic factor and expectations heuristic factor. But for the ASCM route planning this particular issue, node metastasis should also be subject to the direction of target and

the extent of threat. Therefore, we introduce the transfer direction inducing factor (δ(i,j)) to improve the ANT algorithm based on elitist strategy. The value of transfer direction inducing factor reflect the basic judgment of ants on the next shift direction. Based on the transfer direction inducing factor, the improved metastasis probability formula can be written as Eq. 3:

$$P_{ij}^{k} = \begin{cases} \left(\delta_{ij}(t)\tau_{ij}^{\alpha}(t)\eta_{ij}^{\beta}(t)\right) \Big/ \sum_{s \in allowd_k} \delta_{is}(t)\tau_{is}^{\alpha}(t)\eta_{is}^{\beta}(t), & if \quad j \in allowd_k \\ 0, & other \end{cases} \tag{3}$$

In the transfer direction inducing factor $\delta = \begin{bmatrix} \delta_{(-1,-1)} & \delta_{(-1,0)} & \delta_{(-1,1)} \\ \delta_{(0,-1)} & \delta_{(0,0)} & \delta_{(0,1)} \\ \delta_{(1,-1)} & \delta_{(1,0)} & \delta_{(1,1)} \end{bmatrix}$, values of a matrix representing the tendency of the ant from δ(0,0) shift to the eight directions, and determined by the target orientation parameter and level of threat parameter. δ can be written as Eq. 4:

$$\delta_{ij}(t) = Q_s + Q_t = Q_s + \left(\left(k_{t1} r_{ij}\right)/R_{se} + \left(k_{t2} r_{ij}\right)/R_{at}\right) \tag{4}$$

Where, Qs is the target orientation parameter, as shown in Table 1. Qt is the threat level parameters, including the detective threats and intercept threats. r_{ij} is the distance between the ship and node j. Rse is the detection distance of ship. Rat is the intercept distance of ship. Kt is the ratio of relative importance between of detective threats and interceptive threats.

Table 1 Target orientation parameter

Difference between target orientation and δ(i,j)	0º-15º	15º-45º	45º-75º	75º-105º	105º-135º	135º-165º	165º-180º
Values of δ(i,j)	7	6	5	4	3	2	1

ASCM route planning improved ANT model

Analysis of factors route planning

According to ASCM operational mission requirements, route planning has mainly four core factors: the angle of attack, route constraints, penetration ability and concealment.

Angle of attack (Aacm) is factor characterizing the late-guided of ASCM. Favorable angle of ASCM attack not only for maximum target radar cross section, but also to avoid as far as possible shooting range of target ship anti-aircraft weapons.

Route constraints (Racm) are factors characterizing the flight performance of ASCM. It mainly consists of two indicators: the effective range of constraints and routes turning point constraints. The effective range of constraints is the total length of cruise missile route must not exceed its effective range (Rvmax). Routes turning point constraint is the size of turning points in the ASCM route can not exceed the maximum value of the guidance system can be set (Ntpmax).

Concealment (Scam) is factors characterizing the detection threats of target ship. The key to ASCM route planning is to reduce as much as possible detection probability and delayed time were found by target during the flight. So choose exposure flight time (Tuc) and flight distance in the detection range (Luc) to describe the concealment of ASCM. It can be written as Eq. 5:

$$S_{acm} = 1/\left(\mathrm{k_s} L_{uc} + \left(1 - \mathrm{k_s}\right) T_{uc}\right) \tag{5}$$

Penetration ability (Pacm) is factors characterizing the intercept threats of target ship. Target ship equipped air defense missiles, anti-missile guns and electronic jamming system performance determines the size of the penetration ability of ASCM. Therefore, penetration ability of ASCM related to the damage probability of air defense missiles, anti-missile guns and electronic jamming system can be written as Eq. 6:

$$P_{acm} = \left(1 - P_{SAM}\right)\left(1 - P_{AAA}\right)\left(1 - P_{ECM}\right) \tag{6}$$

Construction of route planning model

ASCM target route planning is hidden under the premise as to costs as small as possible, from the perspective of favorable attack surface ships. The objective function can be written as Eq. 7:

$$MaxF = E_i / V_i \tag{7}$$

Where, Ei is the attack effect of the missile when flying along i-th route. Vi is the costs of the missile when flying along i-th route.

Ei including angle of attack and hidden factors can be written as Eq.8:

$$E_i = K_e A_{acmi} + (1-K_e)S_{acmi} = K_e A_{acmi} + (1-K_e)/(k_s L_{uci} + (1-k_s)T_{uci}) \quad (8)$$

Which, Aacmi is the probability of a favorable angle of attack is achieved when the ASCM flying along i-th route. Sacmi is the concealment of the missile when flying along i-th route. Ke is the relative importance ratio of the angle of attack and concealment.

Vi including penetration costs (Vp) and time costs (Vt) can be written as Eq. 9:

$$V_i = K_v V_{pi} + (1-K_v)V_{ti} = \frac{K_v}{P_{acmi}} + (1-K_v)R_i = \frac{K_v}{(1-P_{SAMi})(1-P_{AAAi})(1-P_{ECMi})} + (1-K_v)R_i \quad (9)$$

Which penetration costs (Vpi) is the reciprocal of penetration ability when ASCM flying along i-th route. Time cost (Vti) is the total range when ASCM flying along i-th route. Kv is the ratio of relative importance between of penetration costs (Vp) and time costs (Vt).

ASCM route planning also includes two feasibility constraints. The length of route must not exceed Rvmax. The size of turning points can not exceed Ntpmax. It can be written as Eq. 10:

$$s.t\begin{cases} R_i \le R_{v\max} \\ N_i \le N_{tp\max} \end{cases} \quad (10)$$

ASCM route planning application examples

The target of ASCM is fleet command ship (Sc), in addition fleet also includes six frigates (Sf). ASCM flight speed of 300m/s, Rvmax is 280 kilometers; Ntpmax is 3, Aacm is ±80±15º.

Establish describe information of the node

According combat situation, we can establish the North east coordinate system. ASCM launch at the origin. The distance of target fleet is 192 kilometers, heading 345º. Fleet command ship at (400,500), six frigates position respectively (360,395), (275,498), (331,564), (429,611), (520,515) and (463,442). Mesh node spacing set 300 meters (ASCM one second flight distance).

Route planning conclusion

ASCM route planning simulation using MATLAB programming operations are realized. Ants scale (m) is set to 20, the maximum number of iterations is set to 500, and the maximum number of cycles is set to 10. Specific conclusions of ASCM route planning are shown in Table 2 & Fig.1.

Table 2 Route planning conclusion data

Conclusion of route planning	User's strategies		
	Focus on concealment Rs	Focus on penetration ability Rp	focusing on angle of attack Ra
The flight time of missiles after being found (Sec)	138	155	160
The distance of missiles flight being intercept (Km)	33.1	20.5	35.9
average intensity of the interceptor firepower (Times)	8.61	2.0	4.74
The total flight time of missiles route (Sec)	660	695	780
Angle of attack (º)	120	135	75
The number of turning points in missiles route	1	2	3

For hidden route (Rs), within the detection range of ship, the flight time of missiles is shortest, respectively equivalent to penetration route (Rp) of 89% and aggressive route (Ra) of 86%. Hidden effects of missile are the best; better reflect the user's strategies focusing on concealment. But the anti-aircraft firepower attack missile is the strongest. Within the intercept range of ship, the flight distance of missiles is longer, weakening penetration capability of the missile. Angle of attack not belongs to a favorable angle. For the penetration route (Rp), within the intercept range of ship, the flight distance of missiles is shortest, respectively equivalent to hidden route (Rs) of 62% and aggressive route (Ra) of 57%. The anti-aircraft firepower attack missile is the weakest, respectively equivalent to hidden route (Rs) of 23% and aggressive route (Ra) of 42%. Effect breakthrough defense of missile is the best; better reflect the user's strategies focusing on penetration capability. However, within the detection range of ship, the flight time of missiles is longer, weakening concealment of the missile. Angle of attack not belongs to a favorable angle. For aggressive route

(Ra), the angle of attack is favorable angle. Capture the effect of target ship of missile is the best; better reflect the user's strategies focusing on angle of attack. But within the detection range of ship, the flight time of missiles is longest, equivalent to penetration route (Rp) of 103%, weakening concealment of the missile. Within the intercept range of ship, the flight distance of missiles is longest, equivalent to hidden route (Rs) of 108%. The anti-aircraft firepower attack missile is the stronger, weakening penetration capability of the missile.

Thus, ASCM route planning improved ANT algorithm model can be achieved the goal, meet the constraints, sensitively reflect the user's strategies, and effectively enhance the effect of a missile attack. Improved ANT algorithm introduced by transfer direction inducing factor can be a good match planning goals and a lot of constraints, meet timeline requirements of route planning.

Summary

The ASCM route planning application improved ANT algorithm. First can use ANT algorithm have stronger robustness and the ability to search better solution to solve a large-scale optimization problem of matching missile route planning goals and a lot of constraints. Then based on elitist strategy introduce the transfer direction inducing factor, optimized node metastasis ant direction selection information, solve problems of stagnation because too slow convergence may arise. Future research will also continue to explore ways to enhance synergies between the ants, so as to improve the efficiency of ASCM route planning.

Keywords: intuitionistic fuzzy Sea-battlefield situation assessment

Abstract. Maritime Operations Command premise is a scientific and efficient assessment of the dynamic and varied sea-battlefield. According to research sea-battlefield situation assessment based on improved intuitionistic fuzzy algorithm based on projection. First is based on intuitionistic fuzzy to establish the sea-battlefield situation information matrix. Second is establishing the sea-battlefield assessment criterion vector. Finally, based on the theory of projection, it can compute the proximity of sea-battlefield situation information matrix and sea-battlefield assessment criterion vector, comprehensive and dynamic assess sea-battlefield in different time slices.

Introduction

Sea battle is a complex, dynamic and high risk. Similarly sea-battlefield assessments are mostly uncertain environmental conditions, incomplete information, deal with emergencies under intense time pressure. Therefore, the process and the objects of sea-battlefield assessments are with ambiguity essence. As technology advances, new types of weapons emerging cause the types of sea-battle object increases, while situational awareness means continue to enrich cause the information of sea-battlefield situation is expanding. Therefore sea-battlefield assessment is a dynamic process. In addition a number of different types of sea-battle objects performing their operations and achieving their operational intentions. Sea-battlefield situation assessment requires parallel processing the deep impact of the uncertainty caused by the massive nonlinear potential and random phenomenon.

Atanassov expand Zadeh fuzzy sets is proposed based on membership, non-membership and hesitation of the three aspects of intuitionistic fuzzy sets of information, so that intuition can be more delicate set of fuzzy sets to describe and characterize the objective world than traditional fuzzy vagueness nature. The sea-battlefield assessments are typical ambiguity with nature. In the complex sea-battlefield, the sea-battlefield assessment of many factors to consider, from only a single attribute is difficult to accurately determine the level of threat. In theory, considerations of scale and credibility of the results obtained is proportional. The practice, factors to be considered too, can easily generate combinatorial explosion. Cause sea-battlefield situation assessment process overly complex and difficult to achieve even impossible. The main factors affecting the same time may be annihilate by a lot of secondary factors. So we improved intuitionistic fuzzy algorithm by introducing projection theory. In the situation assessment process, we may be subject to changes in sea battle, based on the projection theory immediate to establish new sea-battlefield assessment criterion vector, used to characterize the dynamic classification rules and potential relationships. By calculating the projection of sea-battlefield situation information matrix on the sea-battlefield assessment criterion vector, it is relatively simple to achieve the current sea-battlefield situation assessment.

Basic concept

Intuitionistic fuzzy sets

The main difference between intuitionistic fuzzy sets and fuzzy sets is that it not only gives the membership on the field a little, but also gives the non-membership.

Intuitionistic fuzzy set theory on domain X is an object of the form: $A=\{\langle x,\mu_A(x),\gamma_A(x)\rangle|x\in X\}$.

Which, $\mu_A(x):X\to[0,1]$is the membership x belong to A, $\gamma_A(x):X\to[0,1]$ is the membership x does not belong to A; and meet the sum: $0\le\mu_A(x)+\gamma_A(x)\le 1,\forall x\in A$.

For intuitionistic fuzzy sets on X, intuition index of x is defined as $\pi_A(x)=1-\mu_A(x)-\gamma_A(x)$. It reflects the degree of x for A hesitate a measure.

When X is a continuous space, intuitionistic fuzzy set A can be expressed as $A=\int_x\langle\mu_A(x),\gamma_A(x)\rangle/x$.

When X is a discrete space, intuitionistic fuzzy set can be expressed as $A=\sum_{i=1}^{n}\langle\mu_A(x_i),\gamma_A(x_i)\rangle/x_i$.

Intuitionistic fuzzy reasoning based on the premise that the physical meaning of the observed data, the establishment of appropriate membership functions and non-membership function, fuzzy observation data.

Projection theory

Because the components of a vector comprising the mold and direction. Either direction or mode can not fully reflect the closeness between vectors. So we choose the cosine of the angle between the vectors to measure the consistency of the direction vectors. We are considering the direction and mold of vector to define the concept of projection. Assuming there is vector $\alpha=(\alpha_1,\alpha_2,....,\alpha_k)\&\beta=(\beta_1,\beta_2,....,\beta_k)$, the projection of α on the β can be written as Eq. 1.

$$\Pr o_\beta(\alpha)=\left(\sum_{i=1}^{k}\alpha_i\beta_i\sqrt{\sum_{i=1}^{k}\alpha_i{}^2}\right)\Big/\left(\sqrt{\sum_{i=1}^{k}\alpha_i{}^2}\sqrt{\sum_{i=1}^{k}\beta_i{}^2}\right)=\sum_{i=1}^{k}\alpha_i\beta_i\Big/\sqrt{\sum_{i=1}^{k}\beta_i{}^2} \tag{1}$$

Generally, the larger value of $\Pr o_\beta(\alpha)$, the closer between the vectors α and β.If β is the ideal situation typical numerical key factor collection, it indicates that the current situation α more closely this typical situation β, which can evaluate the current situation α comply with relevant characteristics typical situation β.

Sea-battlefield intuitionistic fuzzy assessment model

Building sea-battlefield situation assessment model based on improved intuitionistic fuzzy. The first is based on intuition obfuscated sea-battlefield information, build sea-battlefield information matrix described by the intuitionistic fuzzy numbers. Then based on the goal of the sea-battlefield situation assess, build sea-battlefield assessment criterion vector. Based on the theory of projection, sea-battlefield situation assessment is computing the proximity of sea-battlefield situation information matrix and sea-battlefield assessment criterion vector. It can base on existing experience to match the current situation, identify the trend from previous similar experiences situation conducive to the development of one's own action plan for the next step can be implemented under.

Establish sea-battlefield information intuitionistic fuzzy matrix

The object of sea-battlefield situation assessment is sea-battlefield situation in different time slices. Each sea-battlefield situation contains a large number of property information. Establish sea-battlefield information matrix, it must be evaluation each attribute of sea-battlefield situation by intuitionistic fuzzy numbers, and the corresponding form of a matrix formulation. There is n sea-battlefield situation, each situation with m attributes, then the sea-battlefield information intuitionistic fuzzy matrix I ,can be written as Eq. 2

$$I=\begin{bmatrix}(\varpi_{11},\gamma_{11}) & (\varpi_{12},\gamma_{12}) & ... & (\varpi_{1m},\gamma_{1m})\\ (\varpi_{21},\gamma_{21}) & (\varpi_{22},\gamma_{22}) & ... & (\varpi_{2m},\gamma_{2m})\\ ... & ... & ... & ...\\ (\varpi_{n1},\gamma_{n1}) & (\varpi_{n2},\gamma_{n2}) & ... & (\varpi_{nm},\gamma_{nm})\end{bmatrix} \tag{2}$$

We may be appropriate sea-battlefield information intuitionistic fuzzy matrix I into membership matrix I_ϖ and non-membership matrix I_γ.

Establish sea-battlefield assessment criterion vector

Sea-battlefield information intuitionistic fuzzy matrix I contains membership matrix I_{ϖ} and non-membership matrix I_{γ}. Sea-battlefield assessment criterion vector also contains two vectors: action implement criterion vector and action termination criterion vector.

Action implement criterion vector (high threat criterion vector) is ideal numerical collection of sea-battlefield attributes for implementation combat operations, which is the optimal value of membership matrix I_{ϖ} of all the attributes. As $T=\left[t_1,t_2,...t_m\right], T_j=\underset{i}{Max}\varpi_{ij}$。

Action termination criterion vector (low threat criterion vector) is ideal numerical collection of sea-battlefield attributes for the termination of combat operations, which is the worst value of all the non-membership matrix I_{γ} attributes. As $F=\left[f_1,f_2,...f_m\right], F_j=\underset{i}{Max}\gamma_{ij}$。

Calculate sea-battlefield assessment projection

Based on the above analysis and projection theory, we solver when evaluating projected sea-battlefield, also requires solving two projectors. The projection $\Pr o_T(\varpi)$ of sea-battlefield situation information membership matrix I_{ϖ} on the action implement criterion vector T .The projection $\Pr o_F(\gamma)$ of sea-battlefield situation information membership matrix I_{γ} on the action termination criterion vector F, can be written as Eq. 3 and Eq. 4.

$$\Pr o_T\left(\varpi_j\right)=\left(\sum_{i=1}^{m}\varpi_{ij}T_i\sqrt{\sum_{i=1}^{m}\varpi_{ij}{}^2}\right)\Big/\left(\sqrt{\sum_{i=1}^{m}\varpi_{ij}{}^2}\sqrt{\sum_{i=1}^{m}T_i{}^2}\right)=\sum_{i=1}^{m}\varpi_{ij}T_i\Big/\sqrt{\sum_{i=1}^{m}T_i{}^2} \quad (3)$$

$$\Pr o_F\left(\gamma_j\right)=\left(\sum_{i=1}^{m}\gamma_{ij}F_i\sqrt{\sum_{i=1}^{m}\gamma_{ij}{}^2}\right)\Big/\left(\sqrt{\sum_{i=1}^{m}\gamma_{ij}{}^2}\sqrt{\sum_{i=1}^{m}F_i{}^2}\right)=\sum_{i=1}^{m}\gamma_{ij}F_i\Big/\sqrt{\sum_{i=1}^{m}F_i{}^2} \quad (4)$$

Sea-battlefield situation assessment

For sea-battlefield situation, the greater of $\Pr o_T(\varpi)$, the closer to sea-battlefield situation information membership matrix I_{ϖ} with the action implement criterion vector T, then in this situation need to perform this combat operations. The smaller of $\Pr o_F(\gamma)$, the farther from sea-battlefield situation information non-membership matrix I_{γ} with the action termination criterion vector F, then in this situation should be maintained this combat operations. Therefore, when assess sea-battlefield situation, we comprehensive evaluation projections by extreme ways. Therefore, when assess sea-battlefield situation, we comprehensive evaluation projections by extreme ways. If the probability of implemented operations in the current situation is δ, apparent the probability of not implementing operations is $1-\delta$.

Then solving $Max\left(\left(\left(\delta_j\Pr o_T(\varpi_j)\right)^2+\left(\left(1-\delta_j\right)\Pr o_F(\gamma_j)\right)^2\right)\right), j=1,2,...,n$, can get a comprehensive assessment of the conclusions of current sea-battlefield situation, can be written as Eq. 5.

$$\delta_j=\left(\Pr o_T(\varpi_j)\right)^2\Big/\left(\left(\Pr o_T(\varpi_j)\right)^2+\left(\Pr o_F(\gamma_j)\right)^2\right), j=1,2,...,n \quad (5)$$

Sea-battlefield situation assessment application examples

Below we take aviation threat of sea-battlefield situation assessment as an example to illustrate the application of intuitionistic fuzzy based on projection. There are 6 samples for assessment.

Establish situation information matrix

Sea-battlefield situation assessment is closely related in type of troops, the relative position, relative distance and combat operations and other factors. Select the situation attribute should contain sufficient information to ensure that the basis on as succinct as possible. Because the action is against the fundamental tactical situation assess. Based on an in-depth analysis, we selected five properties to

build the intuitionistic fuzzy matrix, namely R (the distance between the surface vessels and air force), ES (surface vessels whether to implement electronic interference), AS (whether surface vessels implement avoidance maneuver), EA (Air Force is implementing electronic anti-interference) and IA (Air Force whether the external information support). Sea-battlefield situation information intuitionistic fuzzy matrix specific data are shown in Table 1.

Table 1 Sea-battlefield situation information intuitionistic fuzzy matrix table

Time slice	R	ES	AS	EA	IA
0	（0.2，0.7）	（0.7，0.3）	（0.5，0.4）	（0.3，0.5）	（0.4，0.5）
1	（0.3，0.4）	（0.8，0.2）	（0.5，0.5）	（0.5，0.5）	（0.5，0.5）
2	（0.1，0.6）	（0.5，0.3）	（0.6，0.2）	（0.5，0.4）	（0.5，0.4）
3	（0.1，0.7）	（0.3，0.7）	（0.1，0.5）	（0.9，0.1）	（0.1，0.6）
4	（0.3，0.6）	（0.2，0.8）	（0.4，0.5）	（0.8，0.2）	（0.8，0.2）
5	（0.9，0.1）	（0.7，0.2）	（0.6，0.4）	（0.8，0.1）	（0.9，0.1）

Corresponding membership matrix I_{ϖ} and non-membership matrix I_{γ} of sea-battlefield situation information intuitionistic fuzzy matrix I can be written as Eq. 6.

$$I_{\varpi}=\begin{bmatrix}0.2&0.7&0.5&0.3&0.4\\0.3&0.8&0.5&0.5&0.5\\0.1&0.5&0.6&0.5&0.5\\0.1&0.3&0.1&0.9&0.1\\0.3&0.2&0.4&0.8&0.8\\0.9&0.7&0.6&0.8&0.9\end{bmatrix},I_{\gamma}=\begin{bmatrix}0.7&0.3&0.4&0.5&0.5\\0.4&0.2&0.5&0.5&0.5\\0.6&0.3&0.2&0.4&0.4\\0.7&0.7&0.5&0.1&0.6\\0.6&0.8&0.5&0.2&0.2\\0.1&0.2&0.4&0.1&0.1\end{bmatrix} \quad (6)$$

Establish situation assessment criteria vector

According to analysis of historical data, action implement criterion vector of sea-battlefield aviation threat is $T=[0.8,0.4,0.4,0.9,0.8]$, action implement criterion vector is $F=[0.5,0.9,0.6,0.5,0.6]$.

Calculate situation assessment projection

According to the projection formula (3) and (4), we can solver projections $\Pr o_T(\varpi)$ & $\Pr o_F(\gamma)$ of sea-battlefield information intuitionistic fuzzy matrix at sea-battlefield aviation threats situation assessment criterion vectors, specific data as shown in Table 2.

Table 2 Sea-battlefield situation assessment projection table

Time slice	$\Pr o_T(\varpi)$	$\Pr o_F(\gamma)$
0	0.933	0.981
1	1.133	0.865
2	0.935	0.892
3	0.551	1.435
4	0.852	1.075
5	1.531	0.641

Assess sea-battlefield situation

It can use sea-battlefield situation assessment intuitionistic fuzzy model to assess the sample value obtained sea-battlefield aviation threat situation assessment conclusions, shown in Fig.1.

Analysis sea-battlefield situation assessment intuitionistic fuzzy model to assess value available: at t=1 time slice, air force and surface vessels were not to take any countermeasures, air force can normally detect, identify and target surface ships approaching. Determine the level of the threat to aviation is less high, and showed an increasing trend, assessment concluded that surface vessels to be taken against action - avoidance maneuver. At t=2 time slice, surface vessels implementation of avoidance maneuver, air force occupation attack position more difficult. Determine the level of the threat to aviation is medium, and is decreasing, evaluation concluded that surface vessels to maintain avoidance maneuver and need to take further action - implementing electronic interference. At t=3 time slice, surface vessels implementation of electronic interference and avoidance maneuver; air force detection means to be blind, unable to find surface vessels. Determine the level of the threat is low, and is decreasing, evaluation concluded that surface vessels to maintaining the existing

operations, air force may be taken against action. At t=4 time slice, surface vessels implementation of electronic interference and avoidance maneuver, air force implementation of electronic anti-interference, ability to detect certain aviation recovery, but no find surface vessels again. Determine the level of the threat to aviation is less low, and showed an increasing trend, evaluation concluded that surface vessels to maintaining the existing operations, air force may take further action. At t=5 time slice, surface vessels implementation of electronic interference and avoidance maneuver, air force implementation of electronic anti-interference and external information support, via the external detection means get the position of surface vessels, to achieve the attack element solver and binding. Determine the level of the threat to aviation is high, and increasing trend, evaluation concluded that surface vessels need to take further against action.

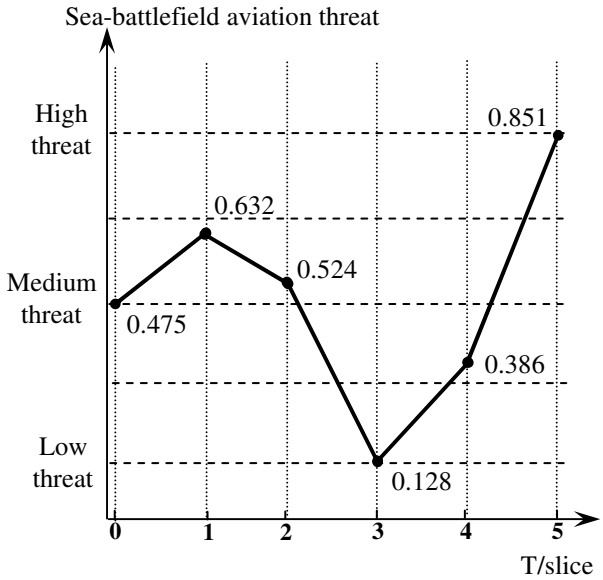

Fig.1 Sea-battlefield aviation threat situation assessment conclusions

Thus situation assessment conclusions of sea-battlefield intuitionistic fuzzy assessment model basically credible. Meanwhile intuitionistic fuzzy method based on projection can works well with dynamic changes such as situation property richen in sea-battlefield, enhanced sea-battlefield situation assessment timeliness.

Conclusions

The sea-battlefield situation assessment application improved intuitionistic fuzzy methods. First can use intuitionistic fuzzy sets can be a wealth of information attribute classification ability to address the problem of the sea-battlefield situation assessment of the fuzzy relationship between objects and factors; then by based on the projection of the relative theory, immediate introduction of a new criterion for membership to solve combinatorial explosion due to the many Sea-battlefield objects and factors arising. Future research will continue to explore the generation rules of assessment criterion vector, in order to improve the efficiency of establish of the sea-battlefield situation assessment intuitionistic fuzzy mode.

Keywords: information entropy, cost sensitive, Support Vector Machine, imbalanced data set

Abstract. As a supervised classification algorithm, Support Vector Machine (SVM) has an excellent ability in solving small samples, nonlinear and high dimensional classification problems. However, SVM is inefficient for imbalanced data sets classification. Therefore, a cost sensitive SVM (CSSVM) should be designed for imbalanced data sets classification. This paper proposes a method which constructed CSSVM based on information entropy, and in this method the information entropies of different classes of data set are used to determine the values of penalty factor of CSSVM.

Introduction

The traditional classification method is mainly for balanced data set and supposes that the cost of misclassification of each sample is equal. With the goal of better accuracy of classification, the conventional classifier devotes to improve operation efficiency and generalization ability. However, in a practical application, the data sets are always imbalanced, which means the number of some kind sample is far less than the number of other classes. The assumption that all kind of samples have the same cost of misclassification will make classifier be partial to majority class and seriously degrade classification performance. Therefore, the traditional classifier can't meet the demands of data mining in reality. This is where the cost-sensitive classification comes in. The cost-sensitive classification takes different samples with different costs of misclassification into account, and it is a new research hotspot of data mining. [1-3]

SVM is a new pattern classification method developed in recent years. It bases on statistical learning theory and structural risk minimization principle, so SVM can get the global optimum solution. SVM has special advantages when it resolves problems about small samples, non-linear and high dimensions. However, SVM itself does not have cost sensitivity, and it can not be used directly for the classification of imbalanced data sets.

This paper proposes a new CSSVM based on information entropy, which constructs CSSVM by setting different penalty factors for different classes and uses information entropy of different classes of data set to determine the value of penalty factors of CSSVM. The experimental results show that this method has better classification performance on imbalanced data sets than others.

Cost-sensitivity Support Vector Machine

Basic principle of Support Vector Machine. SVM is a powerful tool for finite samples and nonlinear classification problem. It basic principle is to find the most optimal hyperplane in a two-class classification problem. The hyperplane can maximize margin between two classes, while maintaining the accuracy of classification. Therefore, the SVM can have good generalization ability. In theory, SVM can realize optimization classification for the linearly separable data set. For

nonlinear classification problem, SVM uses a kernel function to map the sample datasets into a high-dimensional feature space and solves the problem as linearly separable problem.

Assume that the training sample set S={(x_i,y_i)},where i=1..n,x_i∈Rn, y_i∈{+1,-1} and +1,-1 represent identifiers of two class separately. When the training samples are linearly separable, SVM needs to find the most optimal hyperplane $\omega \bullet x_i + b = 0$, which divides all samples into two kinds while maximizing margin $2/\|\omega\|$. When the training sample set is nonlinearly separable or it can not be judged linearly separable in advance, misclassification is allowed and slack variables $\xi_i \geq 0$, i=1,2,..n is introduced. SVM is minimum of Eq. 1under the restrict conditions.

$$\phi_{\min}(\omega,\xi) = \frac{1}{2}(\omega \bullet \omega) + \mathrm{C}\left(\sum_{\mathrm{i}=1}^{1} \xi_{\mathrm{i}}\right) \qquad (1)$$

$$s.t. \quad \mathrm{y}_i(\omega \bullet x_i + b) \geq 1 - \xi_i, \qquad \xi_i \geq 0, \quad i = 1,2...,n$$

In Eq. 1, *C* is penalty factor which measures the degree of misclassification. The higher the value of *C*, the greater the punishment of misclassification will be. Penalty factor *C* controls the trade-off between model complexity and misclassification. If the value of *C* is too big or too small, SVM will have bad generalization ability. So, it is important to set a proper value for *C*.

Basic principle of CSSVM. Different sample has different costs of misclassification in cost-sensitive classification. Given the function of penalty factor *C* in SVM, CSSVM can be constructed by choosing different penalty factor C^+ and C^- for positive and negative class in SVM, respectively. C^+ represents the cost of misclassifying positive samples as negative class, and C^- represents the cost of misclassifying negative samples as positive class. These can make different kinds of sample with different misclassification cost and the SVM has the property of cost-sensitivity [4].The model of CSSVM is shown as Eq. 2:

$$\phi_{\min}(\omega,\xi) = \frac{1}{2}(\omega \bullet \omega) + \mathrm{C}^+\left(\sum_{i \in I+} \xi_i\right) + \mathrm{C}^-\left(\sum_{i \in I-} \xi_i\right) \qquad (2)$$

$$s.t. \quad \mathrm{y}_i(\omega \bullet x_i + b) \geq 1 - \xi_i, \qquad \xi_i \geq 0, \quad i = 1,2...,n$$

In Eq. 2, *I*+, *I*- are the sets of positive and negative examples respectively. [5]

In general, there are two common ways to determine the values of penalty factor C^+ and C^-. The first way is cross-validation. In this way, when a experiment is to be made, penalty factor C^+, C^- and the parameters of kernel function should be given initial values in advanced. Then the values of penalty factor C^+ and C^- should be kept on revising according to the results of experiments until satisfaction. This parameter selection method is based on experience and in lack of theoretical support, so it is with certain blindness. Moreover, there will be different way to adjust parameter according to different kernel function. And when the range of adjustment or the number of adjustment is larger, the experiment will take a longer time. [6]The second way is using the number of two samples to determine the values of penalty factor, that is $\frac{C^+}{C^-} = \frac{n_num}{p_num}$, n_num represents the number of negative class and p_num represents the number of positive class. [7] The second way's theoretical foundation is thinking that the problem of imbalanced data set classification is cased by different classes differ largely in the numbers .[8] Prati et al. had done a series of comparative experiments to study how the imbalance within a class or among classes has a big influence on the performance of classification. However, the experimental results showed that sometimes the drop in classification performance did not cause by imbalanced data, but caused by overlapping of the samples among classes, and the classifier can still get a good classification performance in imbalanced data set, so long as classes did not overlap seriously. [9] According to the experimental results, the distributions of different class's samples in space largely affect the

classification performance of imbalanced data set, and the overlapping of classes is the main affecting factor. So while the above method which uses the number of two samples to determine penalty factor is simple and easy, it is not very effectively.

CSSVM Based on Information Entropy

Information entropy is the measurement of informational probability which is included in a set of data, and it can be taken as a measure of uncertainty. [10] Information entropy was provided by Shannon in 1948 and its calculating formula is $H_s(p_1,\cdots,p_n)=-\sum_{i=1}^{n} p_i \log p_i$.

Information entropy represents the out-of-order extent of system. The more orderly samples distribute in space, the smaller information entropy's value. It is found that, under the same conditions, if a class's number is fewer, it will have the more diverse and uncertain in space distribution, and its value of information entropy is larger. So the value of information entropy can better reflect the distribution of samples in space. While constructing a CSSVM, the value of information entropy of each class can be used to set up the corresponding value of penalty factor. The specific formulas are as Eq. 3 and Eq. 4 .

$$C^{+}=-\frac{p_num}{total_num}\log_2\frac{p_num}{total_num} \tag{3}$$

$$C^{-}=-\frac{\mathrm{n}_num}{total_num}\log_2\frac{\mathrm{n}_num}{total_num} \tag{4}$$

While plugging Eq. 3 and Eq. 4 into Eq. 2, CSSVM Based on Information Entropy can be gotten as shown in Eq. 5.

$$\phi_{\min}(\omega,\xi)=\frac{1}{2}(\omega\bullet\omega)+(-\frac{p_num}{total_num}\log_2\frac{p_num}{total_num})*\left(\sum_{i\in I+}\xi_i\right)+(-\frac{\mathrm{n}_num}{total_num}\log_2\frac{\mathrm{n}_num}{total_num})*\left(\sum_{i\in I-}\xi_i\right) \tag{5}$$

$$s.t.\quad \mathrm{y}_i(\omega\bullet x_i+b)\geq 1-\xi_i,\qquad \xi_i\geq 0,\quad i=1,2...,n$$

Experimental results

Cost-sensitivity classifier's evaluation criteria. There is low proportion of minority class in imbalanced data set. If the total accuracy is taken as evaluation criteria of classification effect, the algorithm will ignore the minority class and focus on improving the classification performance for majority class. Under this condition, the classifier can still achieve high precision, even if all minority class samples are misclassified. Therefore, it's not appropriate for taking total accuracy as evaluation criteria of classification effect in imbalanced data set. In recent years, people have provided many evaluation criteria which are appropriate for imbalanced data set classification. The most common of these evaluation criteria are F-measure[11] and G-means[12].

Assume that minority class is positive class and majority class is negative class in imbalanced data set. Positive class is expressed as P, and negative class is expressed as N. FP（False Positives）represents the number of misclassification that the samples of majority classes are taken as minority classes. FN（False Negatives）represents the number of misclassification that the samples of minority classes are taken as majority classes. TP (True Positives), TN (True Positives) represent the numbers of samples be properly classified into minority class and majority class, respectively. We define the precision of classification as the ratio between the number of true positive predictions and the number of positive instances that is judged by the classifier: Precision = TP/ (TP+FP). The sensitivity of

classification which is also called recall is defined as ration between the number of true positive predictions and the number of positive instances in the data set: Recall = TP/(TP + FN).

The precision and recall of classification are important indicators which are used to measure classification performance. The higher the values of precision and recall of classification, the better the classifier is. However, in large data set, these two indicators restrict mutually. In order to find the balance between them, the precision and recall of classification can be combined into one, such as F-measure and G-means, as shown in Eq. 6, Eq. 7.

$$F-measure=\frac{2\cdot \mathrm{Re}\,call\cdot \mathrm{Pr}\,ecision}{\mathrm{Re}\,call+\mathrm{Pr}\,ecision}=\frac{2}{1/\mathrm{Re}\,call+1/\mathrm{Pr}\,ecision} \quad (6)$$

The value of F-measure is harmonic mean of precision and recall, which can be used to estimated the classifier's ability of making a distinction between two different types. The larger the value of F-measure, the values of recall and precision approximate to 1, and the classifier has better performance.

$$G-means=\sqrt{\mathrm{Precision}\cdot \mathrm{Re}\,call} \quad (7)$$

G-means is the geometric average of precision and recall. It reflects balance of classifier's classifying ability towards two-class classification problem. The larger the value of G-means, the classifier has better performance.

Experimental Data Sets. To verify the performance for binary classification of CSSVM Based on Information Entropy in imbalanced data set, several two-class data sets in the international machine learning standard database UCI are selected. The detailed informations of these data sets are shown in Table 1.

Table 1 The description of data sets

Data set	Number of attributes	Number of positive class	Number of negative class	Ration between Positive class and negative class
haberman	4	81	225	0.3176
pima	9	268	500	0.536
breast-cancer	10	85	201	0.4229
tic-tac-toe Endgame	10	332	626	0.5304

Performance evaluation of algorithms. In this section, CSSVM Based on Information Entropy is compared with standard SVM, CSSVM Based on the Numbers of Sample, the ID3 algorithm of decision tree and BP neural network on their classification effect in the data sets mentioned in Table 1. In these experiments, ten fold cross validation method is used, the mean values of F-measure and G-means are used as evaluating indexes, and Gaussian function is selected as kernel function for SVM, CSSVM Based on the Numbers of Sample and CSSVM Based on Information Entropy.

Table 2 The results of experiments

Dataset	methods	F-measure	G-means
haberman	ID3	0.023	0.027
	BP	0.413	0.421
	SVM	0.021	0.019
	CSSVM Based on the Numbers of Sample	0.539	0.487
	CSSVM Based on Information Entropy	0.726	0.712
pima	ID3	0.481	0.423
	BP	0.726	0.731
	SVM	0.479	0.401
	CSSVM Based on the Numbers of Sample	0.715	0.707
	CSSVM Based on Information Entropy	0.801	0.764

breast-cancer	ID3	0.278	0.317
	BP	0.401	0.426
	SVM	0.323	0.412
	CSSVM Based on the Numbers of Sample	0.578	0.502
	CSSVM Based on Information Entropy	0.856	0.841
tic-tac-toe Endgame	ID3	0.334	0.431
	BP	0.761	0.772
	SVM	0.427	0.398
	CSSVM Based on the Numbers of Sample	0.621	0.511
	CSSVM Based on Information Entropy	0.862	0.843

The experimental data in Table 2 show that the values of F-measure and G-means of CSSVM Based on Information Entropy for the imbalanced data set mentioned in Table 1 are higher values than four others'. This indicates that CSSVM Based on Information Entropy has better classification performance in imbalanced data set and is superior to four others.

Conclusion

Imbalanced data set is the data set which is imbalanced in the number of samples of each class or in the spatial distribution in the spatial distribution. When classifying imbalanced data set, we should take account of not only classification precision but also the cost of classification. Due to traditional SVM's classification performance and precision drop significantly in imbalanced data set, this paper presents a new CSSVM Based on Information Entropy which use Gaussian function as kernel function and choosing different penalty factor C^+ and C^- for positive and negative class, respectively. The values of penalty factor C^+ and C^- can be determined by the corresponding class's information entropy value which reflects the characteristics of the data set itself. The experiments show that CSSVM Based on Information Entropy has better classification effect, and it has higher forecasting accuracy for minority class.

Keywords: Local fuzzy classifier; global classifier; Support vector machine; k-nearest neighbor classifier

Abstract. This paper proposes an assembling classifier consisting of a global classifier and a local classifier, named as GCLC. To this end, we present a weighted Support Vector Machine (wSVM) that serves as the global classifier, and a fuzzy k-nearest neighbor (fkNN) that serves as the local one. When a query arrives, wSVM labels it firstly. If the global decision is below some threshold, the local fkNN works to provide an improved decision. Extensive experiments on real datasets demonstrate the performance of GCLC compared with the state of the art.

1. Introduction

Classification algorithm learns decision model from labeled data and applies the learned classifier to unlabeled data. If take a further look, we find the classifiers can be divided into two groups: the global ones and the local ones. The global classifiers, like Support Vector Machine (SVM) [1], derive class membership based on the global discriminative information of the whole training data. The local ones, on the contrary, like k-nearest neighbor (kNN) [2], detect labels according to the neighboring information around the query.

Since global classifier and local classifier are valid in respective situations, this paper proposes a natural idea to combine them together, with intention to let them cooperate with each other. We present a weighted Support Vector Machine (wSVM) that serves as the global classifier, and a fuzzy k-nearest neighbor (fkNN) that serves as the local one. When a query arrives, wSVM labels it firstly. If the global decision is below some threshold, the local fkNN works to provide an improved decision. The advantage of GCLC is that it avoids the overly high cost consumed by the global classifier, and is expected to provide a qualifier decision on difficult points.

2. wSVM

For l samples: (x_1, y_1) (x_2, y_2)……(x_l, y_l) sampling from $X \times Y$, where $X = R^n$, $Y = \{1, -1\}$. SVM seeks below hyperplane, where K is the Gaussian Kernel:

$$g(x) = \sum_i \alpha_i y_i K(x_i, x) - b \tag{1}$$

The support value α and offset vector b are obtained by optimizing:

$$\max_{\alpha} \ \sum_i \alpha_i - \frac{1}{2} \sum_i \sum_j \alpha_i \alpha_j y_i y_j K(x_i, x_j) . \tag{2}$$

$$\text{s.t. } 0 \le \alpha_i \le C_{svm} , \ \sum_i \alpha_i y_i = 0 .$$

Points with $0 < \alpha_i < C_{svm}$ are nbSV. bSV is points with $\alpha_i = C_{svm}$.

In M-class data environment, the 1-vs-rest way is used to construct basic SVM for each class to separate it from other classes. The hyperplane of J^{th} class is $g_J(x)$. Given the query Q, the size of Q's neighborhood NS, we weight basic SVMs with its confidence on the decision with respect to Q. Most existing approaches concerned with SVM decision reliability estimate analyze posterior distribution of SVM output. They collect the responses of neighboring classifiers centered at the original SVM on the same query, and evaluate original SVM output according to behaviors of neighboring models.

This paper stands at another point of view that is to investigate the responses of the original SVM model over query's neighborhood; then formulate the local distribution for output based on these responses; and finally evaluate original SVM confidence according to its decision-consistency on this neighborhood. That is, we *find an appreciate neighborhood of query* a local context for output with help of query's neighborhood, and extract statistics of outputs over this region to form confidence definition.

In details, wSVM consists below steps.

1) Specify the distance computation schema as:

$$Ld(x, y) = \sqrt{2-2k(x,y)} \tag{3}$$

2) Compute Q's variance: $s^2 = ave\ \{Ld(Q, x)^2 | x \in NEI(Q)\}$. *NEI* represents the neighborhood of Q, and *ave* computes the mean of the distance within the neighborhood. Actually s^2 tells the decision-consistency amount. The smaller s^2 is, the more steady the decision of SVM is. Besides output variance, other two factors are influential: neighborhood density and $f_J(Q)$ value itself.

3) Take above factors into consideration, and we compute the confidence coefficient of g_J with respect to the query Q:

$$\mu_J(Q) = \exp(-\frac{s^2 \cdot \bar{d}}{|f_J(Q)|}). \tag{4}$$

with $\bar{d} = \frac{\Sigma_{x \in NEI(Q)}\ dis(x,Q)}{NS}$ being the mean distance of the neighborhood.

4) Let L_1 = max $\{\mu_J(Q) f_J(Q)\}$ and L_2 = second max $\{\mu_J f_J(Q)\}$, with $J = 1...M$.

5) If $L_1 - L_2 > \varepsilon$, where ε is the pre-specified threshold, then $label(Q) = L_1$; otherwise $label(Q) = FL(Q)$. $FL(Q)$ is the fuzzy membership function that is defined in following section.

3. fkNN

$FL(Q)$ is defined as:

$$FL(Q) = \exp(-\bar{d}) \cdot \frac{MajorL}{NS} \tag{5}$$

Therein *MajorL* is the number of the neighbors belonging to the most frequent class within Q's neighborhood. The underlying rationale of employing the inverse proportion information of $\bar{d}$ in *FL* function is that the lower the mean distance of the neighborhood, the more confident the decision of the local classifier is.

Another important problem is to specify *NS*. As mentioned above, the data-adaptive size is expected to benefit the classification quality. Thus we learn *NS* from the distribution of data.

With the distance information generated by above $Ld(x, y)$ formula, we sort the training data according to their closeness to Q. That develops the new list $\{x_i\}$, with $Ld(Q, x_i) <= Ld(Q, x_{i+1})$, ($i = 1...N$). *NS* is self-tuned as:

$$NS = \max_j \{\frac{\exp(Ld(Q,x_j) - Ld(Q,x_{j-1}))}{\exp(Ld(Q,x_{j-1}))}\} \tag{6}$$

The motivation of above specification of *NS* is that we look for the max gap of the distance list. That gap reveals the inherent region around Q where data are clustered closely. In another word, that region is dense region around Q. Therefore it is rationale to use such a region as Q's neighborhood.

4. Experimental Results

4.1 Benchmark Datasets

Firstly we take the benchmark datasets of UCI [3] as the experimental datasets. In each dataset, 30% data are sampled randomly as the training data. And the classification error ratios reported below is the mean accuracy of 20 independent runs. The optimal results are presented in bold style.

In Table 1, GCLC is compared with kNN [2], two SVM-based classifiers [4], C4.5 [5], Machete [6], Scythe [6], DANN [7], and Adamenn [8]. C4.5 is standard classifier based on decision tree idea. The last four approaches are the representatives that devote efforts to learn new metrics and label data according to the distance generated by the new metrics. From experiments, it is easy to know that GCLC and Adamenn work better than others classifiers and they all provide the lowest error ratios in 4 out of 5 datasets. That demonstrates the performance of GCLC. If take the high cost consumed by Adamenn to tune six parameters during the classifier training process, GCLC exhibits more popularity in practice.

Table 1. Comparisons on classification error ratio (%) (The optimal result is shown in bold style)

Data	*k*NN	SVM_{lr}	SVM_{l1}	C4.5	Machete	Scythe	DANN	Adamenn	GCLC
Wine	7.79	5.83	6.15	8.92	7.11	6.03	6.2	**5.28**	5.3
Iris	6.0	4.1	4.0	7.7	5.1	4	5.8	**3**	**3**
Sonar	12.5	11	12	23.1	21.2	16.3	9.7	**8.5**	**8.5**
Liver	31.5	28.4	27.2	38.3	28.5	29.1	30.1	27.3	**26.6**
Vote	7.8	3	2.6	3.4	3.3	3.3	**3**	**3**	**3**

Among other classifiers, DANN achieves best accuracy since it extracts dimension relevance and defines wise distance definition with considerate probability modeling. The jobs of two SVM-based classifiers are moderate. The main reason lies in some factors. Firstly the performance of the basic SVM could be affected with the existence of multi classes. After all SVM is originally developed for binary-classification instead of multi-classification. Secondly the assembling manners do importance on the final decision since they are problem-dependent. The high error ratios of two SVM-based classifiers also show the advantage of the proposed idea that integrates the global SVM with the local classifier. kNN works poorly due to its weak ability to handle overlapping region.

4.2 Real Datasets

Then GCLC is performed on News group [9]. This dataset contains about 20,000 articles (email messages) evenly divided among the 20 newsgroups. We label each newsgroup as follows: NG1: alt.atheism; NG2: comp.graphics; NG3: comp.os.ms.windows.misc; NG4: comp.sys.ibm.pc.hardware; NG5: comp.sys.mac.hardware; NG6: comp.windows.x; NG7: misc.forsale; NG8: rec.autos; NG9: rec.motorcycles; NG10: rec.sport.baseball; NG11: rec.sport.hockey; NG12: sci.crypt; NG13: sci.electronics; NG14: sci.med; NG15: sci.space; NG16: soc.religion.christian; NG17: talk.politics.guns; NG18: talk.politics.mideast; NG19: talk.politics.misc; NG20: talk.religion.misc.

Table 2. Comparisons on classification error ratio on News Group (%) (Number in the bracket is the number of data sampled from corresponding class or classes)

Dataset	*k*NN	SVM_{lr}	SVM_{l1}	C4.5	Machete	Scythe	DANN	Adamenn	GLMF
{NG2,NG3,NG4} (300)	32.0	30.8	31.9	37.7	33.1	34.4	35.8	**30.2**	30.67
{NG2(150), NG3(50), NG4(200)}	33.79	30.8	31.2	34.92	31.07	31.02	31.46	31.2	**29.03**
{NG6, NG7,NG8}(150)	17.5	16.4	15.96	17.1	15.92	15.3	16.7	15.7	**15.18**
{NG6(200),NG7(150), NG8(350)}	15.95	15.1	16.3	18.3	16.5	15.2	14.8	**14.17**	14.37
{NG1, NG2,NG7, NG8}(200)	15.8	13.2	12.98	14.4	13.83	13.74	13.65	**12.5**	12.69
{NG1 (50), NG2(100),NG7(150),NG8(50)}	14.9	13.8	13.9	13.55	13.72	12.68	**13.0**	13.8	**13.0**
{NG7(100),NG8(50), NG12(200), NG16(50),NG17(100)}	15.6	12.3	12.3	14.7	12.9	12.2	11.64	12.5	**12.0**

We apply the usual *tf.idf* weighting schema to express documents. Set vector $x_i = (x_{i1}, x_{i2}, ..., x_{im})'$ for each document. Here $x_{ij} = t_{ij} \cdot \log \frac{n}{df_j}$, t_{ij} is the appearance frequency of word f_j in document d_i, n is the number of documents, and df_j is the number of documents that contain word f_j. We delete words that appear too few times and normalize each document vector to have unit Euclidean length.

Table 2 lists the experimental results. Clearly GCLC outperforms its peers by presenting the optimal results in 4 out of 7 cases. And SVM_{1r} does a better job than SVM_{11} in most cases. C4.5 and Machete work poorly in some sets due to their greedy idea. Scythe modifies the greedy nature and thereby achieves better accuracy. The metric employed by DANN approximates the weighted Chi-squared distance, which causes it fails in datasets of non-Gaussian distribution. Adamenn works well in some cases, but its huge cost affects its popularity in practice.

5. Conclusion

This paper proposes an idea of combining a global classier and a local classifier to improve classification accuracy, and realizes this idea by the proposed weighted SVM and the fuzzy kNN as global and local classifier respectively. We weight basic SVM with the confidence of its decision. If the decision of global model is of low confidence, local fkNN is used to refine decision. fkNN is developed in an informative neighborhood. Experiments on toy and real datasets demonstrate the fine performance of GCLC.

Keywords: On-orbit modal identification; binocular stereo vision; 3D reconstruction

Abstract: The modal of large flexible structure with low and close modes hardly computes accurate data in the ground. While binocular stereo vision is valued for non-contact measurement, greater flexibility and higher precision in on-orbit identification method. This paper optimized the binocular vision algorithm. The difference between original and new algorithm, which includes the aiming-point number, the identification time and the memory number was shown. The conclusion manifests that new algorithm can improve the identification accuracy and speed up the identification and provide support for on-orbit modal identification.

Introduction

In recent years, the large flexible structures such as antenna and solar panels are widely applied on the satellite[1].Due to the features of low and close modes, it is hard to reduce by themselves when the vibration begins[2].the ground experiment is difficult to simulate the complex working environment of satellite, so the on-orbit modal identification is more important. The traditional method employs sensors, but the flexible structures are influenced by added mass, and on-orbit space is limited. And binocular stereo vision can conduct non-contact measurement and achieve the effect of real-time monitoring[3]; it is more flexible and accurate. Using two high resolution digital industrial camera, binocular stereo vision shoots antenna model and aiming points from two angles, then proceeds 3D reconstruction automatically, and the coordinates of points can be got on model surface. this paper optimizes binocular vision algorithm, saves the testing time and improves the identification accuracy and efficiency.

1 Binocular vision three-dimensional reconstruction technology

1.1 The principle of binocular vision technology

The binocular vision technology is shooting with two cameras to process the image recognition, then we can calculate the parameters which are to be tested. The process unifies the coordinates of two cameras, so the first step is calibrating the camera parameter. Four kinds of coordinates will be used: world coordinate $O-XYZ$, image coordinate $O-XY$,pixel coordinate $O-UV$ and light coordinate $O-X_cY_cZ_c$.

1.2 The calibration of parameter of camera system

Through the transformation of coordinates, the relationship between image coordinate and world coordinate can be shown:

$$Z_c\begin{bmatrix}u\\v\\1\end{bmatrix}=\begin{bmatrix}f/dx & 0 & u_0 & 0\\0 & f/dy & v_0 & 0\\0 & 0 & 1 & 0\end{bmatrix}\begin{bmatrix}R & t\\0^T & 1\end{bmatrix}\begin{bmatrix}X\\Y\\Z\\1\end{bmatrix}=NM\begin{bmatrix}X\\Y\\Z\\1\end{bmatrix}=Q\begin{bmatrix}X\\Y\\Z\\1\end{bmatrix} \quad (1)$$

N:The internal parameter matrix of the camera. M:The outside parameter matrix of the camera. Q:Projection matrix. The Zhengyou Zhang calibration Method[4]is used to calibrate the internal parameter matrix of the camera.

Order: $\alpha_x = dx / f$, $\alpha_y = dy / f$,with N^{-1} premultiplicate eq(1) .

Order: $k = \alpha_x (u - u_0)$, $l = \alpha_y (v - v_0)$, $M = [R \quad t]$. And it can be further expanded to the following three equations:

$$\begin{cases} Z_{ci} k_i = m_{11} X_i + m_{12} Y_i + m_{13} Z_i + m_{14} \\ Z_{ci} l_i = m_{21} X_i + m_{22} Y_i + m_{23} Z_i + m_{24} \\ Z_{ci} = m_{31} X_i + m_{32} Y_i + m_{33} Z_i + m_{34} \end{cases} \tag{2}$$

Substitute the 3rd equation of eq(2) to the above equations to eliminate Z_{ci} , taking n points in the world coordinate, it will produce n equations, these equations are written in matrix form:

$$\begin{bmatrix} X_1 & Y_1 & Z_1 & 1 & 0 & 0 & 0 & 0 & -k_1 X_1 & -k_1 Y_1 & -k_1 Z_1 \\ 0 & 0 & 0 & 0 & X_1 & Y_1 & Z_1 & 1 & -l_1 X_1 & -l_1 Y_1 & -l_1 Z_1 \\ & & \cdots & \cdots & \cdots & & & & & & \\ & & \cdots & \cdots & \cdots & & & & & & \\ X_n & Y_n & Z_n & 1 & 0 & 0 & 0 & 0 & -k_n X_n & -k_n Y_n & -k_n Z_n \\ 0 & 0 & 0 & 0 & X_n & Y_n & Z_n & 1 & -l_n X_n & -l_n Y_n & -l_n Z_n \end{bmatrix} \begin{bmatrix} m_{11} \\ m_{12} \\ m_{13} \\ m_{14} \\ m_{21} \\ m_{22} \\ m_{23} \\ m_{24} \\ m_{31} \\ m_{32} \\ m_{33} \end{bmatrix} = \begin{bmatrix} k_1 m_{34} \\ l_1 m_{34} \\ k_2 m_{34} \\ l_2 m_{34} \\ \cdots \\ \\ \\ \\ \cdots \\ k_n m_{34} \\ l_n m_{34} \end{bmatrix} \tag{3}$$

Inferring from eq(3) visible, if known the coordinates of N points in world and pixel coordinate, it doesn't impact on solving equations that Dividing both sides by m_{34} $(m_{34} \neq 0)$ or take $m_{34} = 1$ .Eq(3) can be abbreviated as

$$Kh = U \tag{4}$$

When 2n>11, solving the above linear equations by generalized least squares, the solution is

$$h = \left(K^T K\right)^{-1} K^T U \tag{5}$$

The external parameter matrix of the camera has the following relationships

$$M = m_{34} \begin{bmatrix} h_1 & h_2 & h_3 & h_4 \\ h_5 & h_6 & h_7 & h_8 \\ h_9 & h_{10} & h_{11} & 1 \end{bmatrix} \tag{6}$$

R is orthogonal matrix, so

$$m_{34} = 1 / \sqrt{h_9^2 + h_{10}^2 + h_{11}^2} \tag{7}$$

1.3 The improvement of image Harris corner detection algorithm

After photogrammetry, data needs to be deeply processed. For detecting the aiming points, Harris corner detection algorithm is used. In order to solve the problem of isotropic, Harris corner detection algorithm abstracts similarity of each point to:

$$E_{x,y} = \sum_{u,v} w_{u,v} [I_{x+u,y+v} - I_{u,v}]^2 = \sum_{u,v} w_{u,v} [xX + yY + o(x^2, y^2)]^2 \tag{8}$$

Among

$$\begin{cases} X = I \otimes (-1, 0, 1) \approx \delta I / \delta x \\ Y = I \otimes (-1, 0, 1)^T \approx \delta I / \delta y \end{cases} \tag{9}$$

So, when the displacement is enough small, $E(x, y) = Ax^2 + 2Cxy + By^2$

Among

$$\begin{cases} A = X^2 \otimes w \\ B = Y^2 \otimes w \\ C = (XY) \otimes w \end{cases} \tag{10}$$

To solve the response noise, the algorithm uses a Gaussian smoothing filter window. It is achieved through the setting of w.

Wherein $w_{u,v} = \exp\left[-(u^2+v^2)/2\delta^2\right]$. $E(x,y)=(x,y)M(x,y)^T$, $M = \begin{bmatrix} A & C \\ C & B \end{bmatrix}$.Harris corner response function is expressed as

$$R(x,y) = \det(M) - k \bullet tr^2(M) \tag{11}$$

In eq(11), k is a constant, $\det(M) = AB - C^2$, $tr(M) = A + B$.When $R(x,y)$ exceeds a predetermined value, it means that the point is the corner. In the actual process, the computation is large, so usually using the corner amount cim detect:

$$cim = \frac{AB - C^2}{A + B} \tag{12}$$

Qing [5] has been used for three-dimensional positioning, based on the amount of corners can be improved as follows:

(1)Using eq(10) for image filtering, making use of horizontal and vertical difference to calculate I_x I_y, and find the corner response function cim of I_x^2 and I_y^2;

(2) When the gradient between corner response function value of cim and surrounding eight pixel points is maximal, extracts this corner point as candidate;

(3)When the candidate for corner points come to duplication, using neighborhood maxima filtering and adjusting the gradient threshold to obtain the final corner points.

2 Experimental

In this paper, the antenna model is photographed using industrial high-speed cameras. As shown in fig.1, nine aiming points were set on the antenna model before measuring. After calibrating of the camera's internal and external parameters, the antenna model is measured by using binocular stereo vision measurement.

Fig.1 Shooting scene (left) and model calibration point (right)

As shown in fig.2 and in table 1, adopting the same gradient threshold, the original algorithm only finds 6 points and takes 926.4808 seconds for every 100 pictures; the improved algorithm can detect 9 points and only takes 13.6194 seconds for every 100 pictures.

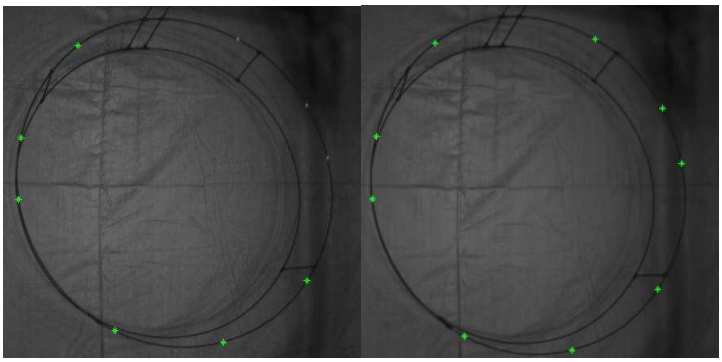

Fig.2 The case of corner detection:originally(left) and improved algorithm (right)

Table 1 The time and memory required to detect images

Number of images	Time of original algorithm [s]	Time of improved algorithm [s]	Memory of original algorithm [kb]	Memory of improved algorithm [kb]
1	9.0775	0.1886	13596	13524
10	91.6249	1.2253	129456	126300
50	467.0899	5.5150	651960	632188
100	926.4808	13.6194	1314058	1293240
500	4645.7648	69.6052	6678246	6471868
1000	9271.3106	136.2610	13204851	12934804

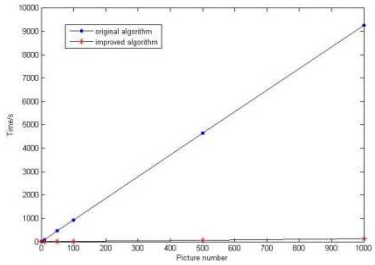

Fig.3 Variation of detection time with detection picture numbers

3 Conclusion

For large flexible structures with low and close modes in on-orbit modal identification, this paper optimizes the binocular vision algorithm. As shown in fig.3, the conclusion indicates that gradient thresholds are equal, the improved algorithm all the calibration points can be detected, the accuracy is improved obviously, the time of detecting pictures is reduced by one order of magnitude, the memory decreases slightly, and the time of on-orbit modal identification are greatly reduced.

Keywords: Rough set theory, Uncertain reasoning, Rules set, Expert system, Algorithm.

Abstract. An algorithm of uncertain reasoning which more than one result of a new object can be obtained according to the known knowledge is an important part of an expert system. A new object is an especial decision rule which has only a predecessor. In order to resolve the problem that the differences of attributes' importance in the new object are not considered in traditional methods of uncertain reasoning, a new uncertain reasoning algorithm based on the rules set which is obtained on the basis of the rough set theory is proposed. In the algorithm, both subjective factors and objective factors in the process of reasoning are considered, and the proportion of subjective factors to objective factors can be controlled by users. So the algorithm is better than the tradition method in flexibility and practicability.

Introduction

The uncertainty reasoning [1] is an important issue in research of expert system. In recent years, many scholars have studied on this question, and many algorithms on the question have been put forward. But these methods have a common disadvantage that the user's subjective factors have not been taken into account.

A new algorithm of uncertainty reasoning based on the rough set theory [2] which can obtain the set of rules is proposed in the paper, and each attribute's importance of the new object is considered in the process of uncertainty reasoning. In the method, both the subjective factors such as the user's needs, interests and the objective factors such as the rules set, amount of support are synthetically reflected, and the proportion of the subjective factors and the objective factors can be adjusted according to the actual needs of the users. So the shortcomings of the traditional uncertainty reasoning methods are overcome, and the needs of users can be reflected more precisely.

Notations and Definitions

The uncertain reasoning is carried out based on rough set theories in the paper. A conclusion of the new object can be obtained by reasoning according to the rules set which is computed by means of simplification of a decision table based on rough set theories. In order to present the algorighm of uncertainty reasoning, notations and definitions that are germane to the paper will be introduced.

Decision tables [3, 4, 5] which can be defined in terms of knowledge representation systems are kinds of prescription, which specifies what actions should be undertaken when some of conditions are satisfied. A knowledge representation system is a pair $K =< U, A >$, where U is a nonempty and finite set, and A is a nonempty, finite set of primitive attributes. Every primitive attribute $a \in A$ is a total function $a: U \to Va$, where Va is the set of value of a, called the domain of a. Let $C, D \subset A$ be two subsets of attributes, called condition and decision attributes respectively. The knowledge representation system with distinguished condition and decision attributes will be called a decision table, and will be denoted $T =< U, A, C, D >$.

Any implication $\alpha \to \beta$ will be called a decision rule [6, 7] and denoted r in the rough set theory; α and β which are formula of the form $(a_1, v_1) \wedge (a_2, v_2) \wedge ... \wedge (a_n, v_n)$ are referred to as the predecessor and the successor of $\alpha \to \beta$ respectively, where a_i ($i = 1, 2, ..., n$) is a attribute of a decision table and v_i ($i = 1, 2, ..., n$) is the value of the attribute a_i. A new object can be seen as a predecessor of a rule and will be denoted x.

Condition attributes of a decision rule r are defined as attributes which are in the predecessor α of the decision rule r, and all condition attributes of a decision rule r will be called a set of condition attributes and will be denoted $S_CA(r)$. A condition attributes set of a new object x will be denoted $S_CA(x)$.

Let $T =< U, A, C, D >$ be a decision table and a sample of the decision table T can be represented as $(a_1, v_1) \wedge (a_2, v_2) \wedge ... \wedge (a_n, v_n) \to (a_{n+1}, v_{n+1}) \wedge (a_{n+2}, v_{n+2}) \wedge ... \wedge (a_{n+m}, v_{n+m})$, where $a_i \in C$ ($i = 1, 2, ..., n$), $a_{n+i} \in D$ ($i = 1, 2, ..., m$), and v_i ($i = 1, 2, ..., n+m$) is the value of the attribute a_i. Let $r: \alpha \to \beta$ be a decision rule, if $(a_1, v_1) \wedge (a_2, v_2) \wedge ... \wedge (a_n, v_n) \to \alpha$, the sample of the decision table can be called a support of the decision rule r. In a decision table, the number of samples which are supports of the decision rule r will be called the degree of support of decision rule and will be denoted $\sup port(r)$.

A set of decision rules which are obtained by means of simplification of a decision table based on rough set theories will be denoted RUL. Let x be a new object, if there is a decision rule $\alpha \to \beta$ satisfying $x \to \alpha$, the rule $\alpha \to \beta$ will be called matching the new object x. A matching set of the new object x consists of all decision rules which match the new object x, and will be denoted $RUL(x)$.

Three situations as follows will be obtained by comparing the new object with every rules of the set of decision rules:

(1) The new object matches a rule or several rules whose decision attributes' values are same.

(2) The new object matches several rules whose decision attributes' values are not same.

(3) The new object does not match any decision rules.

According to above situations, a reasoning of a new object will be called certain reasoning in the first case, and will be called uncertain reasoning in the other cases. In the paper, only uncertain reasoning will be discussed.

An Algorithm of Uncertain Reasoning Considering Subjective Factors

In order to acquire a conclusion of a new object in the process of uncertainty reasoning, every possible conclusion should be given a weight. In more recent years many scholars have researched the question. And traditional methods [8] of uncertainty reasoning include *the method of object tracking*, *the method of attribute voting*, *the method of complete matching*, and so on. All the methods aforesaid have a common defect that attributes importance of the new object are not considered in the process of reasoning, so an algorithm of uncertain reasoning considering subjective factors will be presented in the paper, and the algorithm will be introduced according to two situations of uncertainty reasoning.

An algorithm of uncertain reasoning considering subjective factors when $RUL(x) \neq \phi$,

When $RUL(x) \neq \phi$, the algorithm of uncertain reasoning considering subjective factors can be described as follows:

Step1: Allot a degree of significance with every attribute a of the new object which will be denoted $Sig(a)$, where $0 \le Sig(a) \le 1$ and $\sum_{a \in S_CA(x)} Sig(a) = 1$.

Step2: Computer the fit degree of every conclusion in the matching set of the new object x which will be denoted $fit(x, \beta)$, and

$$fit(x, \beta) = \sum_{a \in \bigcup_{\alpha \to \beta \in RUL(x)} S_CA(\alpha \to \beta)} Sig(a) \qquad (1)$$

Step3: Standardize fit degrees of all the conclusions in the matching set of the new object x by the formula (2):

$$norm_fit(x, \beta) = \frac{fit(x, \beta)}{\sum_{\beta \in dec(x)} fit(x, \beta)} \qquad (2)$$

Where $dec(x) = \{\beta \mid \alpha \to \beta \in RUL(x)\}$. Because the significance degree of the attribute in the new object is allotted according to subjective factors of users, normal fit degrees $norm_fit(x,\beta)$ which are computed according to the significance degree of the attribute will be called subjective weight of conclusion β too.

Remark

There is a condition that $\sum_{\beta \in dec(x)} fit(x,\beta) \neq 0$ in the formula (2). But in fact, the situation $\sum_{\beta \in dec(x)} fit(x,\beta) = 0$ is existent in the process of uncertain reasoning. In order to improve the problem, $0 < Sig(a) < 1$ should be followed.

Step4: compute the general weight $Weight(x,\beta)$ by the formula (3):

$$Weight(x,\beta) = \theta norm_fit(x,\beta) + (1-\theta) reliability(x,\beta) \quad (3)$$

Where $reliability(x,\beta)$ which is the reliability of the conclusion β is computed by plenty of historical data, and $reliability(x,\beta) = votes(\beta)/norm(x)$, where $votes(\beta) = \sum_{r \in R_\beta} \sup port(r)$, $R_\beta = \{\alpha \to \beta \mid \alpha \to \beta \in RUL(x)\}$, $norm(x) = \sum_{r \in RUL(x)} \sup port(r)$. $reliability(x,\beta)$ reflects objective factors of reasoning, and does not consider subjective factors, so the reliability of the conclusion β can be called objective weight of conclusion β. In the formula (3), θ will be called the ratio of subjective factor, and $0 \le \theta \le 1$. When the value of θ is bigger, subjective factors is attached more importance by decision makers. Especially, when $\theta = 1$, only subjective factors are considered in the process of reasoning. When $\theta = 0$, only objective factors are considered, and the algorithm of uncertain reasoning turns to traditional algorithm.

The following property is obvious:

(1) $0 < W(x,\beta) < 1$ (2) $\sum_{\beta \in dec(x)} W(x,\beta) = 1$

Step5: Select the conclusion whose value of general weight is maximum as the final result of reasoning.

An algorithm of uncertain reasoning considering subjective factors when $RUL(x) = \phi$

In order to introduce the algorithm of uncertain reasoning considering subjective factors in the second case, namely $RUL(x) = \phi$, there are two definitions should be given.

Definition1: the matching degree of a rule r and a new object x can be defined as formula (4)

$$match(x,r) = \sum_{a \in S_CA(r) \wedge v_a = v_a'} Sig(a) \quad (4)$$

Where v_a and v_a' are condition attribute a of rule r and attribute a of the new object respectively.

Definition2: If there is a rule r in the set of rules satisfying $match(x,r) \ge \varepsilon$, the rule r can be called partial matching the new object x, where ε is a given value, and $0 < \varepsilon < 1$. A partial matching set of the new object x consists of all the rules satisfying $match(x,r) \ge \varepsilon$, and will be denoted $PRUL(x,\varepsilon)$.

The partial matching set of the new object x $PRUL(x,\varepsilon)$ which can be obtained according to compute the matching degree of every rule in the set of rule can be classified three cases.

(1) $PRUL(x,\varepsilon) = \phi$.

(2) $PRUL(x,\varepsilon) \neq \phi$, and conclusions of rules in $PRUL(x,\varepsilon)$ are unique.

(3) $PRUL(x,\varepsilon) \neq \phi$, and conclusions of rules in $PRUL(x,\varepsilon)$ are not unique.

According to above definitions, the algorithm of uncertain reasoning considering subjective factors when $RUL(x) = \phi$ will be presented as shown in Fig.1.

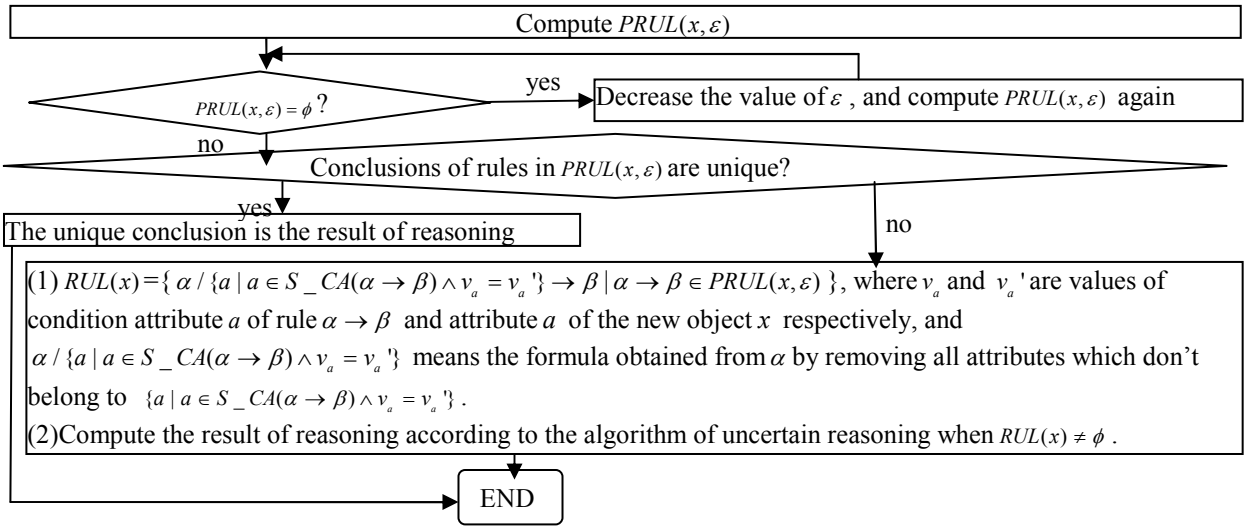

Fig.1. The algorithm of uncertain reasoning considering subjective factors when $RUL(x) = \phi$

Limits on the algorithm of uncertain reasoning considering subjective factors

The given algorithm of uncertain reasoning considering subjective factors overcomes shortcomings of traditional uncertain reasoning methods, and the result of uncertain reasoning is more suitable for user's demands. But there are two restrictive conditions in the process of reasoning using the algorithm of uncertain reasoning considering subjective factors.

(1) The new object x should satisfy $S_CA(x) \supseteq \bigcup_{r \in RUL} S_CA(r)$.

(2) The degree of significance with every attribute a of the new object should satisfy $0 < Sig(a) < 1$.

The two restrictive conditions illustrate that all attributes of the new object are useful in the process of reasoning. That is to say, for the accuracy of reasoning users should provide more detailed information.

Conclusions

An algorithm of uncertain reasoning considering subjective factors is proposed in the paper, and the algorithm considering differences between significances of attributes in the new object overcomes defects of traditional reasoning method. The ratio of subjective factors is leaded into the process of reasoning in the new algorithm. Both subjective factors and objective factors are taken into account in the process of uncertain reasoning, and the proportion of subjective factors to objective factors can be adjusted by the ratio of subjective factors, so the algorithm is better than the tradition method in flexibility and practicability. But there are some shortcomings in the method of uncertain reasoning proposed in the paper, for example, there are two restrictive conditions in the process of reasoning, the accuracy of reasoning is poor in special circumstances, and so on. The algorithm must be researched forward.

Keywords: rough set, attributes reduction, fuzzy set, similarity relation matrix

Abstract. The evaluation algorithm is based on the attributes of data objects. There is a certain correlation between attributes, and attributes are divided into key attributes and secondary attributes. This paper proposes an algorithm of attribute reduction based on rough set and the clustering algorithm based on fuzzy set. The algorithm of attributes reduction based on rough set is described in detail first. There are a lot of uncertain data of customer clustering, so traditional method of classification to the incomplete data will be very complex. Clustering algorithm based on fuzzy set can improve the reliability and accuracy of web customers.

Introduction

Following the rapid development of electronic commerce, which brought a huge number of customer groups, and how to classify and evaluate the customers is very important. According to the customer's transactions, characteristics of the customer information, customers can be classified and evaluated and given the levels. Web services can be improve efficiency in the future based on the actual conduct of targeted customer , and increase customer attention and interest level, thereby enhancing the profitability of web[1].

Because of the object characteristics of things with a particularly high dimension vector property description, make it difficult to conduct effective evaluation, and comparison between the calculated vector will further increase the capacity of things. Rough set is a new mathematical tool to deal with incomplete and uncertain knowledge, and its main feature is not given in advance the number of certain characteristics or properties described, but the problem can directly derived from the classification of knowledge of a given starting indiscernible relation[2]. The data objects can export a minimum feature set of attributes, and do not affect the classification accuracy of the dimension of feature vectors. Since many uncertainties in the value of the attributes, the clustering algorithm of key attributes is designed based on fuzzy set after attributes reduction.

Algorithm Analysis

1. Attributes reduction

LDA topic model shown in Fig.1 is a kind of probability model[3]. Where, α and β are the document-topic and topic-word Dirichlet distribution parameters respectively; M is the total number of documents corpus, T is the number of topic, N_d is number of words in document d. θ is a probability distribution of topics in document, φ is a probability distribution of words in topic. The probability that w_i belonging to topic k is shown in (1)[4].

Data object is described as S = (U, A), U is the set of objects and A is the set of attributes. Some attributes is redundant, while maintaining the same classification ability of the objects, we can delete these redundant attributes, that is, knowledge reduction, after reduction of excess property can obtain the minimum attributes set. If ind (B) = ind (B-{a}), where B belongs to A, a ∈A, so attributes of B can be reduced. A set of objects may exist in several attributes reductions, and the

reductions are defined as the intersection of nuclear effects in the classification of important attribute. Stratified and hierarchical analysis using fuzzy comprehensive evaluation of key attributes is to determine the level of a certain standard of measuring and comparing the various factors, and then give their relative importance quantitative form, the proportion of weight matrix by calculating the weight ratio of the largest eigenvalue matrix and its corresponding orthogonal eigenvectors can be obtained by the level of the weight of each factor[5]. Algorithm design steps are described as follows.

(1) According to the actual situation of data objects, we can select some attributes as evaluation attributes.

(2) The set of attributes reduction can be derived from discernibility matrix and discernibility function. Discernibility matrix is shown in (1).

$$M(B) = \{m\ (i,\ j)\ |\ n \times n,\ 1 \le i,\ j \le n\} \tag{1}$$

where, m (I, j) = {a ∈ A | a (i) ≠ a (j) and d (i) ≠ d (j)}, n = | U |.

(3) Discernibility function is shown in (2). Σ is "∨", Π is "∧".

$$\Delta = \prod_{(i,j) \in U \times U} \sum m(i,j) \tag{2}$$

(4) Attribute reduction and nuclear can be derived from the minimal disjunctive of distinction function.

2. Fuzzy clustering analysis

Customer's attribute can be web transactions based on behavioral characteristics, also it can be static characteristics of the customer, and the attribute can be looked as the basis for cluster analysis. In the classification process, the keywords are divided into different classes for different levels of customer types. Membership function will convert all the data values less than or equal to 1, so the next step of the fuzzy clustering can be carried out[6].

Fuzzy set A in the domain U, with a membership function to describe it, namely: U → [0,1], for any u ∈ U, there is u →μ_A(u), μ_A(u) ∈ [0,1], μ_A (u) is the membership of element u to set A, which represents the degree of u belongs to A[7]. The designing of fuzzy superposition evaluation algorithm is shown as follows.

(1) Let U be the customer domain, U_i is the No.i customer, i ∈ 1,2,3 ... n, A_j is the No.j attribute of U, j ∈ 1,2,3 ... m, S_{ij} is the value of U_i and A_j, P (K_j) is the weighting coefficients of A_j. The membership function of keyword property value is: $\mu_A(S_{ij}) = F(S_{ij}) / (S_{1j} + S_{2j} \ldots S_{nj}) * P(K_j)$.After pretreatment customers, we can design an appropriate fuzzy clustering algorithm of customer data.

(2) Set up the fuzzy similarity relation R of U. The order of R matrix is |U|, m is the number of attributes. Using Euclidean distance formula shown in (3), we can calculate the matrix elements of r_{ij} in R.

$$r_{ij} = \begin{cases} 1 & i = j \\ \sqrt{\frac{1}{m}\sum_{k=1}^{m}(sik - sjk)^2} & i \ne j \end{cases} \tag{3}$$

(3) The graph G = (V, E) can be obtained by R, and the maximum spanning tree as T = (V, TE) from G can be calculated using Prim algorithm.

(4) According to the practical problems to set an appropriate λ ∈ [0,1], T (e) is the weight of edge e, if T (e) <λ, edge e will be removed, the connected component is the classification based on λ.

(1) Let T be the customer domain, T_i is the ith topic, i∈ 1,2,3 ... n, w_j is the jth word in corpus, j ∈ 1,2,3 ... m, s_{ij} is the element of matrix M(n×m),the value of s_{ij} is the probability of word w_i belonging to T_j.

(2) Set up the fuzzy similarity relation R of T. Using Euclidean distance formula shown in (4) , we can calculate the matrix elements of r_{ij} in R.

$$r_{ij} = \begin{cases} 1 & i = j \\ \sqrt{\frac{1}{m}\sum_{k=1}^{m}(S_{ik} - S_{jk})^2} & i \neq j \end{cases} \quad (4)$$

(3) The graph $G = (V, E)$ can be obtained by R, and the maximum spanning tree as $T = (V, TE)$ from G can be calculated using Prim algorithm.

(4) According to the practical problems to set an appropriate $\lambda \in [0,1]$, $T(e)$ is the weight of edge e, if $T(e) < \lambda$, edge e will be removed, the connected component is the clusters based on λ.

Example Analysis

Data objects is shown in Table 1. It includes objects U_1 ...U_{10} and attributes A_1 ...A_n. We take Top 5 attributes for analysis, the distinction matrix is shown in Table 2.

Table 1. Initial Data

U	A_1	A_2	A_3	A_4	A_5
U_1	0.354	0.247	0.500	0.455	0.420
U_2	0.455	0.255	0.085	0.455	0.290
U_3	0.456	0.065	0.500	0.455	0.400
U_4	0.452	0.255	0.530	0.455	0.400
U_5	0.433	0.200	0.134	0.200	0.285
U_6	0.333	0.210	0.500	0.256	0.295
U_7	0.433	0.201	0.604	0.455	0.430
U_8	0.458	0.143	0.500	0.285	0.440
U_9	0.233	0.205	0.403	0.455	0.440
U_{10}	0.459	0.206	0.804	0.200	0.261

Table 2: Distinction Matrix

	U_1	U_2	U_3	U_4	U_5	U_6	U_7	U_8	U_9
U_1									
U_2	1,4,5								
U_3	2,3,4	3,5							
U_4	3,4	3,4,5	2,3						
U_5	2,3,4	1,2,3	1,2,3,4	1,2,4					
U_6	1,2,5	1,4,5	1,2,4,5	1,2,4,5	3,4				
U_7	2,4	1,2,3,5	1,2	1,5	3,4,5	4,5			
U_8	2	1,2,3.4,5	2,4	2,4	1,2,4,5	1,25	1,2,4		
U_9	1,2,4	1,2,3,5	1,2	1,2	3,4,5	1,4,5	2	2,3.4,5	
U_{10}	4,5	2,3,4,5	2,4,5	1,4,5	1,3	2,4	1,4,5	2,4,5	1,3,5

(1) According to Table 2. can get distinction function as follows:

$\Delta = (A_1 \vee A_4 \vee A_5) \wedge (A_2 \vee A_3 \vee A_5) \wedge (A_3 \vee A_5) \wedge (A_3 \vee A_4) \wedge (A_3 \vee A_4 \vee A_5) \wedge (A_2 \vee A_3) \wedge (A_2 \vee A_3 \vee A_4) \wedge (A_1 \vee A_2 \vee A_3) \wedge (A_1 \vee A_2 \vee A_3 \vee A_4) \wedge (A_1 \vee A_2 \vee A_4) \wedge (A_1 \vee A_2 \vee A_5) \wedge (A_1 \vee A_4 \vee A_5) \wedge (A_1 \vee A_2 \vee A_4 \vee A_5) \wedge (A_2 \vee A_4) \wedge (A_1 \vee A_2 \vee A_3 \vee A_5) \wedge (A_1 \vee A_2) \wedge (A_1 \vee A_5) \wedge (A_4 \vee A_5) \wedge A_2 \wedge (A_2 \vee A_3 \vee A_4 \vee A_5) \wedge (A_2 \vee A_4 \vee A_5) \wedge (A_1 \vee A_3) \wedge (A_2 \vee A_4 \vee A_5) \wedge (A_1 \vee A_3 \vee A_5) \wedge = A_2 \wedge A_4 \wedge A_5$

(2) After reduction we can get the key attributes as $\{A_2, A_4, A_5\}$. According to the type of attribute value and the membership function, we can calculate the membership degree of each attribute, and the membership value is as the initial value for classification.

(3) Through the mapping of membership function, original customer data can be initialized, the values are changed to the values less than or equal to 1, and the values reflect the dependence of the attribute.

(4) Fuzzy similarity relation matrix R can be calculated using Euclidean.

(5) The graph G = (V, E) can be derived by R, and the maximum spanning tree T = (V, TE) from G can be calculated using Prim algorithm, where | V | = 10, | TE | = 9. Set λ = 0.310, remove the edge of value less than λ, the connected component is shown in Fig.1.

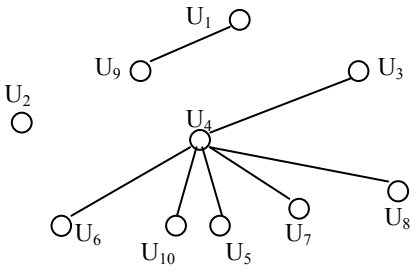

Fig.1 Connected components

(6) Thus, customer classification can be obtained as follows: $C_1 = \{U_3, U_4, U_5, U_6, U_7, U_8, U_{10}\}$,$C_2 = \{U_1, U_9\}$, $C_3 = \{U_2\}$.

Conclusion

The division of attributes at different levels of data objects can provide a more detailed evaluation by key attributes. Rough set method can divide attributes into key attributes and secondary attributes. The evaluation of the key attributes reflects the importance of key attributes, and increases the accuracy and efficiency. Tested by actual data analysis, attributes reduction can reduce the size of customer data and data noise and improve the clustering accuracy of web customers.

The application of Graph Model in the cultural archives

Sun Ping

Department of Management Tianjin University of Technology, Tianjin, China

wy_sp@126.com

Keywords: cultural archives; graph model; similarity measure;

Abstract. This article describes a standard document similarity measure, and is used for cultural archives category. And should be used in the classification of cultural archives. the results show that, based on graph model of this representation is valid and feasible.

1. Introduction

The archives has thousands of years of history, played an important role for human civilization and progress, is a distinct cultural phenomenon. Archive is an important witness of history, management of archives is a respect for history. Cultural Archives refers to people engaged in social and cultural activities in the form of the material, is after a certain collation, classification, cataloguing and filing work according to a certain rule of combining files, it is a true record of the mass cultural activities. It is a witness of China's cultural development, its own significant research value. It is useful to give full play to cultural function of archives work in mass culture.

Document categorization is a complex process, including document pre-processing algorithm design, document presentation, classification, performance appraisal and other major steps, the main task of document categorization document is formalized and classification algorithm based on this design. As computer technology and WWW of universal and rapid development, human social entered has information technology era. this era, while, user can is convenient to through Internet contact to various of information; on the, due to network Shang information of mass features and fast update, user hard in so huge of information marine in the found real by needs of information. in both at home and abroad numerous scholars of long-term efforts and research Xia, currently, series classification algorithm was mention has out. This paper model of an application.

2. Graph model of the document express [1].

Graphical model is a simple and effective method of expressing joint probability distribution of the variables collection [2]. Computers do not have the kind of smart people makes it impossible to read the text. for computers, it can only come from the external features of the text reflects the text of semantic information. entry is reflect the smallest unit of text semantic information, but not all of the entries reflect the semantics of the text information, on the contrary, only a few characteristic vocabulary. Reflect text information in three areas: character entry, location of the characteristic frequency and characteristics of the entry entry. We use the vertices of the graph represents a characteristic of a document entry, and characteristics of which correspond to the two entries in the same window (passage) co-occurrence, embodies the characteristics of location information of the entry; the characteristic frequency of the entry size of the text, determine the size of its entry level co-occurrence with other features. We map each document model expressed in the following form:

$$T = (t_1, t_2, \cdots, t_n) \tag{1}$$

$$A = \begin{pmatrix} a_{12} & a_{13} & \cdots & \cdots & a_{1n} \\ & a_{12} & \cdots & \cdots & a_{2n} \\ & & \cdots & \cdots & \cdots \\ & & & a_{n-2,n-1} & a_{n-2,n} \\ & & & & a_{n-1,n} \end{pmatrix} \tag{2}$$

Among them, the T: feature entry set; t_i: feature entry; A: characteristic triangular matrix associated entries; a_{ij}: feature entry in the associated strength of t_i and t_j ($1 \leqslant i < j \leqslant n$). From the above concept, given the graph G(V,E) corresponding to a document construction method:

(1) Determine the maximum number fixed for each document corresponding to the model n (n can be determined based on experience);

(2) The document preprocessing, and statistic;

(3) Select the feature that best represents the document entry; the number does not exceed n;

(4) For each document D_i, entry by all its features as the vertices of a graph;

(5) Both feature in the same window if the document element (paragraph) co-occurrence, then there is an edge between them, both features and statistics unit entry in the same window (passage) frequency of co-occurrence;

(6) According to the formula (1) determine the characteristics of the entry of the matrix A;

(7) According to the formula (4) normalization to the matrix a, determining the normalized correlation matrix for W.

3. Graph model of document classification method

Now existing document classification method have: KNN, support vector machines, decision trees, linear least squares estimation (LLSF) , Bayesian classification algorithm etc. Among them, the KNN classification method is a stable and efficient algorithm for document classification, compare widely applied in an existing document classification method. It is based on document classification algorithm for instance, the principle of means tests for a given document D, trained by similarity in the documentation set to find the k nearest training documents. K-according to the training document categories to determine the classification of the category values. Similarity can be passed using the Euclidean distance or metric is the cosine of the angle between vectors. K-most similar training documents according to their similarity with the test documents D the level of category value weighted weights in the largest category in the document document d to predict test category value. Document classification in addition to representation, you must also document similarity measure. Different similarity measurement appears different classification results.

Classification algorithm based on graph model Graph-KNN[1]:

Input: training set document $X=\{x_i \in C(x_i)，\ \hat{u}_i=1,2,\ldots,N\}$ and test document y;

Output: test document y may belong to category C(y).

The algorithm steps are:

(1) every document in the training set $x_i \in C(x_i)$, construct the corresponding graph G_i;

(2) construct the graph model G_y for the test document y;

(3) any document $x_i \in C(x_i)$, calculate the similarity of documents for the test x_i in size Sx=Graph Similarity (G_y,G_i);

(4) in accordance with similar size S_x, select documents for testing K the most similar documents, grouped into collections D;

(5) the set D of the share $P(C_i)$ of each category C_i;

(6) return $P(C_i)$ value maximum category y category of belonging as a document.

4. Classification of cultural archives

In this article from a library of cultural archives, randomly tested over more than 1000 documents, these documents covering political, economic, environmental, cultural and historical in five areas. Application of Graph-KNN algorithm based on graph model, running in Chinese natural language processing platform. Among them, the maximum number of vertices of the graph, select K=1,3,5,7,10;n=30; parameter b get 0.6. seen from the result, the feasibility of model classification methods are used to process the document, but the accuracy is not high.

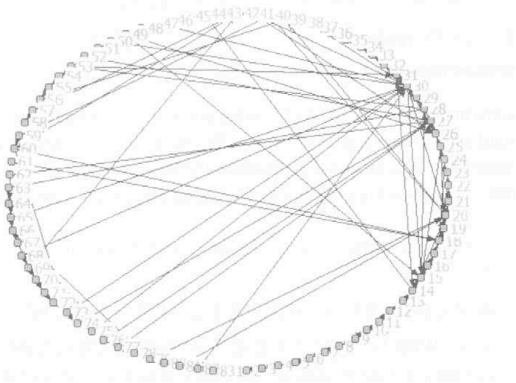

Fig.1 A semantic structure graph of cultural archives

5. Conclusion

Further, study on how to optimize your document representation, enabling it to more effectively communicate the text of semantic information and combining it with more text classification algorithm, used for text classification. on this basis, and finally the graph model for personalized text filtering. Figure model representation of the document into the associated semantic factors are to some extent addressed the characteristic dimension of the extraction and high dimension of vector spaces, makes grammatical and semantic concept words that have the same characteristics of clusters. Feature reduct of document vectors on the expression of the concept is more sophisticated document separation more pronounced. Experiments have shown that this algorithm to improve accuracy and speed of the classification is of great significance.

Keywords: Reverse engineering, instruction trace, binary analysis, deobfuscation

Abstract. Instruction traces are essential for dynamic analysis in reverse engineering. Code in instruction traces is often obfuscated to hinder analysts from understanding and analyzing in malware and binaries that protected by packers. Non-returning calls and call-stack tampering are two typical kinds of such obfuscation. We propose a deobfuscation approach to fight against these two kinds of obfuscated code. We first apply static analysis on instruction traces to identify obfuscated code. Then we transform obfuscated code into semantically equivalent instructions to make the code be easy to understand. Evaluations results on some packed binaries indicate that our approach works well in deobfuscate instruction traces with non-returning calls and call-stack tampering in high precision.

Introduction

Instruction traces are important in dynamic binary analysis. Many works are based on instruction traces, such as dynamic binary disassembly. Dynamic analysis is an important approach for analyzing binary code, such as reverse engineering for malware or binaries protected by packers. Obfuscated code is common in these binaries. Removing obfuscated code contributes to reduce the workload of analysts, and makes the control and data flow clear.

```
0x00401017  call 0x40101C
0x0040101C  pop eax
0x0040101D  add eax, 0xf
…
```

(a) Non-Returning Call

```
0x00401017  pust 0x401028
0x0040101C  ret
0x00401028  inc eax
…
```

(b) Call-Stack Tampering

Figure 1 Examples for non-returning calls and call-stack tampering

In this paper, we focus on two kinds of code obfuscation: non-returning calls and call-stack tampering (Fig. 1). Normally, a call instruction is equivalent to the following operations: push the address of the instruction that immediately follows the call instruction into the stack, and then jump to the target of the call instruction. So a call instruction can be used to complete special tasks, such as obtaining the value of the program counter at runtime. Call-stack tampering misuses return instructions. It replaces an unconditional branch with a push and return instruction.

Current deobfuscation approaches focus on deobfuscation in binary disassembly which is the initial step of binary code analysis. Many works have been done on it [1,2,3,4]. Kruegel et al. assume that all calls are non-returning [1]. They validate code that immediately follows calls by heuristics. Dyninst [4] assumes that calls are non-returning, except the calls proved to be returned by the binary slice on the called functions. If calls are proved not to be returned, instructions that immediately follow calls are not analyzed. Dyninst performs the backward slice on return instructions to determine whether the return instruction jumps to an address as expected. When this try fails, Dyninst obtains the target address by dynamic analysis. These approaches are not suitable for deobfuscating instruction traces because an executable file is quite different from its instruction traces. First, code in instruction traces cannot be statically disassembled because they may be dynamically generated. This makes the instruction at an address be different at different running times. Second, control flow can be transferred by exceptions, return instructions. They cannot be predictable statically. Third, code in instruction traces may be mixed with code from various executable modules, such as system libraries. Binary disassembly approaches that combine static and dynamic analysis such as BIRD [2], can

handle most of the self-modified code. However, they cannot deobfuscate non-returning calls and call-stack tampering because the two kinds of obfuscation only confuse the control flow.

Overview of our approach. To better understand the run-time behavior of binaries, we propose an approach to deobfuscate non-returning calls ans call-stack tampering in instruction traces. We identify non-returning calls by call stack simulation. If the stack value before a call is restored by a pop instruction, the call is not returned. Call-stack tampering are identified by checking whether the instruction adress that is executed after a return instruction is modified by a previous pop the instruction. Then simplify these obfuscated codes and transform them into simple, clear, and semantically equivalent instruction sequences to enhance their comprehensibility.

Definitions

An execution trace represents intuitively a series of operations done by a program during a run on a system. An instruction I is a tuple composed of a memory address A[I] and byte length L[I]. An instruction trace T is a finite sequence (I1, ..., In) of instructions. The stack of the processor is labeled as SP. For an instruction I, the stack value before and after the executed instruction are SP0[i] and SP1[i], respectively. For convenience, non-returning calls and call-stack tampering are called abnormal calls and abnormal returns, respectively. A fall-through address of a call instruction is the address immediately following the call instruction. A call instruction is balanced if the value of SP is restored.

Deobfuscate Non-Returning Calls

Abnormal calls make up a small proportion of all calls in an obfuscated program. So we first find abnormal calls to speed up the deobfuscation.

Identify abnormal calls. Normally, when a call is executed, its fall-through address is pushed into SP, then the control flow jumps to the target. When a return instruction is executed, the return address is popped from SP and the control flow returns to the return address. Therefore, for a call instruction, if its fall-through instruction is not executed after a return instruction or is never executed, the call instruction should be an abnormal call. However, if the fall-through instruction of a call is executed, it does not mean the call is returned because the control flow can be transferred to the fall-through instruction in many ways, such as by a branch instruction.

Fortunately, we can use the stack balance rule to deal with this problem. Because a call instruction pushes a value into SP, there should be an operation that restores the value of SP. Suppose instruction I_j is an abnormal call, and instruction I_k is a pop-like instruction that uses the fall-through address of I_j. Then we have $SP_0[I_j]=SP_1[I_k]$ because SP should be balanced after a call is executed no matter whether the call is a normal or abnormal. We perform the identification with the aid of a stack. Fig. 2(a) gives the identification algorithm. The algorithm visits each instruction in an instruction trace. All calls are pushed into a stack S in turn. If a call is balanced by a return instruction, the call is popped from S because it is normal. If a call is balanced by a pop instruction, it will be identified to be abnormal call. Otherwise, if calls are over balanced, we remove them because their fall-through addresses in SP are overwritten.

Simplify abnormal calls. As abnormal calls may be nested to prevent analysts from understanding, we simplify these calls by the aid of a stack S. For each instruction I_k in $T = (I_0, \ldots, I_n)$, if I_k is an abnormal call, we push I_k into S. If $SP_1[I_k]=SP_0[S.top]$, we pop an abnormal call I_j from S. Then we replace I_j with "jmp target", and replace "pop reg" with "mov reg, C" where $C=A[I_k]+L[I_k]$. The transformation is based on such a principle that instruction "call target" is equivalent to "push C/jmp target". Therefore, "call target/pop reg" can be transformed to "jmp target/mov reg, C" where C is the fall-through address of the call instruction.

Deobfuscate Call-Stack Tampering

Identify abnormal returns. Normally, when a return instruction is executed, the control flow will be transferred to the address that popped from SP. The popped address is the fall-through address of a call instruction. Therefore, if a popped address after an executed return instruction is not the fall-through address of a call instruction, the return instruction is abnormal. The identification process is given in Fig. 2(b). The algorithm visits each return instruction, checking whether the value to be popped from SP is modified by a previous push instruction. If no push instruction is found, the backward searching will be stopped at a normal call or the instruction that holds the SP value greater than the SP value of the return instruction.

Simplify abnormal returns. We transform "push C/ret" to "jmp C" to deobfuscate call-stack tampering. For each instruction I_k in $I = (I_0, \ldots, I_n)$, if I_k is an abnormal return instruction, we search the nearest instruction I_j that $j<k$ and I_j is a push instruction and $SP_0[I_j]=SP_1[I_k]$. Then, I_j is replaced with "nop", and I_k is replaced with "jmp C" where $C = A[I_{k+1}]$.

```
Input: Instruction trace T = (I0, …, In)
Output: Abnormal calls P

For I in T:
  If I is a call instruction:
    S.push(I)
  Else If I is a return instruction:
    If !S.empty() and SP1[S.top] < SP1[I]:
      S.pop()
  Else If I is a pop instruction:
    If !S.empty() and SP0[S.top] = SP1[I]:
      P.append(I)
      S.pop()
    End If
  Else:
    j = S.length – 1
    While j >= 0 and SP1[S[j]] <= SP1[I]:
      S.pop()
      j = j -1
    End While
  End If
End For
```

(a) Abnormal Calls Identification

```
Input: Instruction trace T = (I0, …, In)
Output: Abnormal returns P

For Ik in T:
  If Ik is a return instruction:
    j = k – 1
    While j >= 0:
      If (SP1[Tj] >= SP1[Ik]) or (Tj is a normal call):
        Break
      If Tj is a push instruction and SP1[Tj] = SP0[Ik]:
        P.append(Ik)
      j = j -1
    End While
  End If
End For
```

(b) Abnormal Returns Identidifcation

Figure 2 Algorithm for identifying abnormal calls and returns

Evaluation

Setup. We developed a prototype for evaluation. It consists of an instruction tracer developed using Intel Pin [6], and a static deobfuscation module. In instruction traces, values of registers after an executed instruction are recorded for automatically result validation. An instruction at one address is recorded once for reducing the file size of instruction traces. As non-returning calls and call-stack tampering are common in the meta code of packers (i.e., the code for unpacking), some packed binaries are provided for the evaluation. The sample to pack is compiled by MASM32 and it has only one operation which invokes the system API *ExitProcess*().

Result. Table 1 shows that our approach can deobfuscate abnormal calls and returns in high precision. FP represents false positive. Only several positives are found. If a packer creates multi-threads to unpack binaries, instructions of each thread are mixed in an instruction trace. For example, in Armadillo, the instruction trace includes the following instructions.

```
0x0044DAE7  60       pushad
0x0044DAE8  33 C9    xor ecx, ecx
0x0044DAEA  75 02    jnz 0x0044DAEE
0x0044DBD6  C3       ret
```

The "pushad" and "ret" in the above code are misidentified as call stack tampering because the fall through address of "jnz 0x0044DAEE" should be 0x0044DAEC, not 0x0044DBD6. We carefully

checked the instruction trace, and found that the return instruction at 0x0044DBD6 is belong to other thread. In the result, most of abnormal calls are consecutive call-pop instruction sequences, and most of abnormal returns are consecutive push-ret instruction sequences. In the meta code of Themida, we found that 949 abnormal returns first push 0 into the stack, then modify the value by "mov", for example, "mov [esp+4], ecx". Finally, they use "ret" to transfer the control flow to the specific address.

Table 1 Results of the evaluation on packed binaries

Packer	Version	Abnormal Calls		Abnormal Returns		Precision
		Found	FP	Found	FP	
ASPack	2.29	3	0	2	0	1
Petite	2.2	0	0	0	0	NA
NsPack	3.7	0	0	0	0	NA
FSG	2.0	0	0	0	0	NA
MoleBox	2.3600	2	0	0	0	1
Obsidium	1.3	0	0	15	1	0.93
Armadillo	6.04.0447	100	0	42	1	0.99
ASProtect	2.41	50	0	16	0	1
Themida	1.8.5.5	1018	0	1867	0	1

Conclusion

Instruction traces are tremendously useful in binary dynamic analysis. Obfuscation in traces increases the work load of analysts. Traditional deofuscation approaches aim to deobfuscate code in binary disassembly. They are not suitable for instruction trace deobfuscation because instruction traces are quite different from binary code. We proposed a deobfuscation method to deal with instruction traces including non-returning calls and call stack tampering. We use call stack balance rule to identify abnormal calls and search possible instructions that overwrite the return addresses of return instructions to identify abnormal returns. Then, we transform abnormal calls and returns to semantically equivalent ones that are easy to understand their run-time behavior for subsequent analysis. Experimental results show that our approach can deobfuscate instruction traces with abnormal calls and returns in high precision.

Keywords: Genetic Algorithm; Frieze group; Attractor;

Abstract. The paper introduces Monte Carlo method and Eugenics genetic algorithm, which be used to generate a great diversity of chaotic attractors firstly. By an analysis of their algorithms, a improved eugenics genetic algorithm is presented to avoid the "genetic drift" phenomenon in attractor graphics. A parameter vector distance limit is adopted to solve the problem and lots of experiments applying equivalent mappings of frieze group are finished to validate effectiveness for algorithm.

Introduction

Monte Carlo method can get a large number of random search in the parameter space attractor graphics, but the search success rate are greatly influenced by the scope of the search space, and the success rate under 10%[1]. Therefore, Goertzel [2] from New Zealand proposed Eugenics genetic algorithm. The algorithm is a special application of genetic algorithm, the algorithm used to search the attractor is existing attractor parameter vector after selection, crossover and mutation operations, such as meet the conditions get a batch of attractor parameter vector. He illustrated the algorithm in the experiment by the test equation from Sprott [1], and the compared with his work. He first points out that Sprott chose 25 numbers in the interval [-1.2, 1.2] , if the numbers in the interval [- 12, 12] instead of it, the advantage of eugenics genetic algorithm will be greatly enhanced[2]. Because of less than 10% success rate of Monte Carlo method and eugenics genetic algorithm only affected at the beginning of the test , will eventually run into the correct area. Secondly, Sprott's lyapunov index estimation of each step for a point with a distance of 10 points of iteration, and the results calculated with the difference of (x_{n+1}, y_{n+1}). In some cases, setting number 10 can causes big error when calculating lyapunov index, and adjusting this number may influence the results of the proportion of chaotic attractor. Finally he considers that Sprott regards $x = y = 0.5$ as a general initial point, which it's for practical reasons, there is no try to distinguish between attractors in the whole plane to attract domain, and from a specific initial iteration to get the approximate design is only part of the attractor. We describe the Goertzel's algorithm as follows:

- Firstly, use Monte Carlo method to search out 10-50 different strange attractors structure, with their parameters vector form the IP .
- Select two different parameters $\boldsymbol{p}_{f1}$ and $\boldsymbol{p}_{f2}$ randomly with the same probability.
- Select a breakpoint t randomly ($1 \le t \le n-1$， n for parameter space dimension), generate a second vector $\boldsymbol{p}_c = (c_1, c_2, \cdots c_n)$.
- If second vector fitness conditions ($L \ge 0.05$), select a vector randomly in the IP group, and using $\boldsymbol{p}_c$ as it.

As the above Goertzel algorithm, the model of the p1a1 with 10 different parameter vector group, each generation of children has 10 (generation1) ×10(generation2) ×13(breakpoint location (14-1)) choices, removing the parameter vector lyapunov index does not comply with the conditions, at least 1170*11%=129 eligible parameter vector[2], so the search process can be repeated. But that is not the truth. In the iteration to the initial population after a certain number of times, groups will have the same vector, then the iteration for several times, in the same group of 10 vector, The results are shown

in table 1, this is what Goertzel mentioned in the literature [2] called "genetic drift", which is the further problem discussed in this paper.

The improved eugenics genetic algorithm

Introduction and definition of distance parameter space. Monte Carlo method is put forward by the Sprott' prepotency with eugenics algorithm, their result is effective by using the method of random search or combination, in the parameter space to find more wonderful attractor graphics. But the Monte Carlo method has low success rate of searching attractor and wasting time. But eugenics genetic algorithm accelerated the speed of approaching the chaotic region compared with the former algorithm, and improved the success rate of attractor, but the search process of "genetic drift", eventually led to the search process cannot be continued. Based on the above reasons, this paper introduces the multidimensional parameter vector distance limit, avoids the influence of "genetic drift", defined ρ as follows:

$$\rho(\boldsymbol{a}_p, \boldsymbol{a}_q) = \sqrt{\sum_{i=1}^{n} (a_i - a_i')^2}, \tag{1}$$

which $\boldsymbol{a}_p = (a_1, a_2 \cdots a_n)$, $\boldsymbol{a}_q = (a_1', a_2' \cdots a_n')$ (n is the parameter space dimension, $a_i \in R$, $i = 1, 2 \cdots n$).

The new algorithm description and implementation. To choose the coding principle suitably is an important task for implementation of genetic algorithm, a lot of research work on genetic algorithm is based on the function of the binary sequence that is mapped to a nonnegative real number encoding rules. This paper uses the floating-point coding method in the literature [3-5], which can search accuracy requirement high parameters in parameter space, to save space and search space information transformation process, improve the computational complexity of genetic algorithm and the operation efficiency. In the improved algorithm, the crossover operator uses the single point of intersection for group made up of real number vector, a pair of $\boldsymbol{w}$ and $\boldsymbol{v}$ cross the length n is naturally explain to list items. Randomly choose a dividing point k between 1 and $n-1$, combine the former k of $\boldsymbol{w}$ with later $n-k$ of $\boldsymbol{v}$ in the preceding paragraph of a second vector. According to the experiment, we found that the mutation operator in the search prepotency algorithm of the parameters of the effect is not obvious, the improved algorithm of mutation probability is $p_m = 0$.

The improved eugenics genetic algorithm is as follows:

- Selecting the largest number of iterations $N_{\max}$, the largest escape radius R, and fitness function:

$$f(a) = \begin{cases} 0 & L \le 0.05 \\ 1 & L \ge 0.05 \end{cases}, \tag{2}$$

which L is the Lyapunov index, minimum distance error parameter space is $\rho_{\min}$, the number of iterations is N;

- According to certain scope and step length, using a Monte Carlo search method of M attractor parameter vector as the initial group;
- Choose the two individuals from the initial group as parents with same probability, with floating-point encoding rules, generation $\boldsymbol{p}_{f1}$ and $\boldsymbol{p}_{f2}$ crossover length uses the set of real numbers to exchange the items of the scale, randomly and select breakpoints k from 1 to $n-1$which will be referred to in the preceding paragraph and the consequent combination form a vector offspring;
- Offspring vector Lyapunov index $\boldsymbol{p}_c$, and according to the nature of f, the fitness function of $\boldsymbol{p}_c$ to judge , if $f(\boldsymbol{p}_c) = 0$, turn to step3, otherwise turn step5;
- If the offspring list CIP is empty, build $CIP = \boldsymbol{p}_c$, start the chain table counter, otherwise, for $CIP = \{\boldsymbol{p}_t, t = 1, 2...m\}$, calculating ρ separately:

$$\rho = \rho(\boldsymbol{p}_t, \boldsymbol{p}_c) = \sqrt{\sum_{i=1}^{n} (b_i - c_i)^2} \tag{3}$$

- Randomly select a vector in the group $\boldsymbol{p}_c$ instead of $\boldsymbol{p}$ to form a new group, if $N < N_{\max}$, turn to step 3, otherwise turn to step 7;
- Drawing the attractor, storing data, and choosing the initial group, turn to step1.

The experimental results.

According to the algorithm described above, we apply it to the frieze group with p1a1 model[6,7] as (4) and (5) :

$$f_{p112}\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} a_1 y + a_2 y\cos(x) + a_3 ycox(2x) + a_4 \sin(x) + a_5 y^2 \sin(x) + a_6 \sin(2x) + a_7 y^2 \sin(2x) \\ a_8 y + a_9 y\cos(x) + a_{10} y\cos(2x) + a_{11} \sin(x) + a_{12} y^2 \sin(x) + a_{13} \sin(2x) + a_{14} y^2 \sin(2x) \end{pmatrix} \begin{Bmatrix} 2\pi \\ \infty \end{Bmatrix} \tag{4}$$

$$f_{p1a1}\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} x + a_1 + a_2 y^2 + a_3 ycox(x) + a_4 \cos(2x) + a_5 y^2 \cos(2x) + a_6 y\sin(x) + a_7 \sin(2x) + a_8 y^2 \sin(2x) \\ a_9 y + a_{10} \cos(x) + a_{11} y^2 \cos(x) + a_{12} y\cos(2x) + a_{13} \sin(x) + a_{14} y^2 \sin(x) + a_{15} y\sin(2x) \end{pmatrix} \begin{Bmatrix} 2\pi \\ \infty \end{Bmatrix} \tag{5}$$

In order to further illustrate the superiority of the improved algorithm, we compared several search algorithms, and further showed two models in table 1 in the population of 30 experimental results using a genetic algorithm and improved algorithm, randomly selected from the five groups of different structure of the attractor parameter vector group, each group for 200 generations of evolution, and the evolution process of the necessary data statistics.

By the data in table 1: we can discover that the two models applying eugenic evolution genetic algorithm (GA) 200 generation number is less than improved algorithm search parameters, but generated offspring of high repetition rate, calculated by the prepotency algorithm is relatively low success rate. Under the same experimental conditions, Monte Carlo search method is used for

continuous 200 search with two models respectively, which the parameters space of the model p112 for a1~a7∈ [-5，+5] ，a8~a14∈ [-1，+1], and with the gradient of step length is 0.01, it takes 48 seconds to finish the 1506 parameter vector searches ;Likewise ,the parameters space of the model p1a1 for a1 ~ a15 [2 + 2],and with the gradient of step length is 0.01, it spends 87 seconds searching the 18697 parameter vectors. Comparing two kinds of search algorithms, specially for high-speed computer, search time differ very few and the improved algorithm with spatial distance control, makes the repetition rate is zero, and there is no the same vector in groups. It avoids the "genetic drift" phenomenon fundamentally.

Conclusions

This paper firstly introduces the basic idea of eugenics genetic algorithm, and its application fields of the algorithm which involves the coding principle, several genetic operator is commonly used in genetic algorithm. The second part mainly introduces the search of chaotic attractor of Goertzel prepotency algorithm. According to the combined features of new algorithm formed its own chaotic attractor search on equivalent mappings of frieze group, it was found that the eugenics applied to frieze group mapping in the genetic algorithm, "genetic drift" phenomenon is obvious. For avoiding this, an improved algorithm is proposed in this paper, the key to the algorithm is genetic distance limit, through which the two models in frieze group with the number of groups of 10 and 30 respectively applied to testify the algorithm. Lots of experiments found: while several algorithms used in the search time difference is very small with high-speed computer and prepotency algorithm is applied to group the relative success rate is low, the improved algorithm, with spatial distance limit, makes the amount of repetition rate zero, and avoids the phenomenon of "genetic drift".

Keywords: Jacobi iteration; USSOR iteration; Comparison results; Spectral radius

Abstract. In this paper, some comparison results between Jacobi and **US**SOR iteration for solving nonsingular linear systems are presented. It is showed that spectral radius of Jacobi iteration matrix B is less than that of USSOR iterative matrix under some conditions. A numerical example is also given to illustrate our results.

Introduction

In this paper, we consider the following linear system

$$Ax = b, \tag{1}$$

where A is an $n \times n$ matrix is nonsingular, x and b are n-dimensional vectors.

Iterative methods are effective and practical when the matrix A is large and sparse and are studied by many authors (cf., [1-7], etc).

In order to solve system (1) with iterative methods, the coefficient matrix is split into

$$A = M - N, \tag{2}$$

where M is nonsingular.

The basic iterative method for solving the linear system (1) is

$$Mx^{(k+1)} = Nx^{(k)} + M^{-1}b, k = 0,1,\cdots, \tag{3}$$

where x_0 is an initial vector.

Then (3) can also be written as

$$x^{(k+1)} = M^{-1}Nx^{(k)} + M^{-1}b, k = 0,1,\cdots, \tag{4}$$

where $M^{-1}N$ is called an iteration matrix of the iterative method (4).

It is well-known that the iterative method (3) converges to the exact solution of (1) for any initial vector x_0 if and only if the spectral radius of iterative matrix is less than 1.

Preliminarie

For convenience, some notations, definitions and some results that will be used in the following parts are given below.

A matrix is called nonnegative(positive) if each entry of A is nonnegative(positive), respectively, we denoted them by $A \geq 0 (A > 0)$. Similarly, for an n-dimensional vector x, by identifying it with an $n \times 1$ matrix, we can also define $x \geq 0 (x > 0)$. For $A = (a_{ij}), B = (b_{ij})$, we write $A \geq B$ if $a_{ij} \geq b_{ij}$ holds for all $i, j = 1,2,\cdots,n$, we say that $A - B \geq 0$ if and only if $A \geq B$. For a square matrix A, $\rho(A)$ denotes the spectral radius of A.

Lemma 2.1 [1] Let A be a nonnegative $n \times n$ nonzero matrix. Then

(1) $\rho(A)$, the spectral radius of A, is an eigenvalue;

(2) A has a nonnegative eigenvector corresponding to $\rho(A)$;

(3) $\rho(A)$ is a simple eigenvalue of A;

(4) $\rho(A)$ increases when any entry of A increases.

Lemma 2.2 [2] For $A \geq 0$,

$$\alpha x \leq Ax, x \geq 0, x \neq 0 \text{ implies } \alpha \leq \rho(A)$$

and

$$Ax \leq \beta x, \ x > 0 \text{ implies } \rho(A) \leq \beta .$$

Result and proof

Without loss of generality, let $A = I - L - U$, where I is the identity matrix, $-L$ and $-U$ are strictly lower and upper triangular parts of A, respectively.

The Jacobi iterative matrix is

$$B = L + U = I - A. \tag{5}$$

The USSOR iterative matrix is [3]

$$S_{\omega_1,\omega_2} = (I - \omega_2 U)^{-1}(I - \omega_1 L)^{-1}[(1-\omega_2)I + \omega_2 L][(1-\omega_1)I + \omega_1 U], \tag{6}$$

where ω_1 and ω_2 are real parameters with $\omega_i \neq 0, i = 1,2$.

Let A be the coefficient matrix in (1), B be Jacobi iterative matrix in (4) and nonnegative. Then by Lemma 2.1, we know that B has an eigenvalue $\lambda = \rho(B) \geq 0$.

Theorem 3.1 Let A be a nonsingular matrix, if $0 \leq \omega_i \leq 1$, $i = 1,2$, $B \geq 0$ is the Jacobi iteration matrix in (5), we have that $S_{\omega_1,\omega_2} \geq 0$, where S_{ω_1,ω_2} is the iteration matrix of USSOR iterative method.

Proof Since

$$S_{\omega_1,\omega_2} = (I - \omega_2 U)^{-1}(I - \omega_1 L)^{-1}[(1-\omega_2)I + \omega_2 L][(1-\omega_1)I + \omega_1 U]$$
$$= (I + \omega_2 U + \omega_2^2 U^2 + \cdots)(I + \omega_1 L + \omega_1^2 L^2 + \cdots)[(1-\omega_2)I + \omega_2 L][(1-\omega_1)I + \omega_1 U].$$

As I is the identity matrix ,we have $I \geq 0$, $-L$ and $-U$ are strictly lower and upper triangular parts of A, respectively. We know that

$$L \geq 0, U \geq 0 \text{ when } B = L + U \geq 0.$$
$$1 - \omega_1 \geq 0 \text{ and } 1 - \omega_2 \geq 0 \text{ for } 0 \leq \omega_i \leq 1, i = 1,2.$$

Thus

$$I + \omega_2 U + \omega_2^2 U^2 + \cdots \geq 0, \ I + \omega_1 L + \omega_1^2 L^2 + \cdots \geq 0,$$
$$(1-\omega_2)I + \omega_2 L \geq 0, \ (1-\omega_1)I + \omega_1 U \geq 0.$$

So we obtain that

$$S_{\omega_1,\omega_2} \geq 0.$$

Theorem 3.2 Let the assumption of Theorem 3.1 holds, and $\omega_1 + \omega_2 - \omega_1\omega_2 \leq 1 - \rho(B)$, we have that $\rho(B) \leq \rho(S_{\omega_1,\omega_2})$.

Proof From Lemma 2.1, there exists a vector $x \geq 0, x \neq 0$ such that $Bx = \lambda x$, where $\lambda = \rho(B)$, we have

$$S_{\omega_1,\omega_2} x - \lambda x = (I - \omega_2 U)^{-1}(I - \omega_1 L)^{-1}[(1-\omega_2)I + \omega_2 L][(1-\omega_1)I + \omega_1 U]x - \lambda x$$
$$= (I - \omega_2 U)^{-1}(I - \omega_1 L)^{-1}\{[(1-\omega_2)I + \omega_2 L][(1-\omega_1)I + \omega_1 U] - \lambda(I - \omega_1 L)(I - \omega_2 U)]\}x$$
$$= (I - \omega_2 U)^{-1}(I - \omega_1 L)^{-1}\{[(1 - \omega_1 - \omega_2 + \omega_1\omega_2)I + \omega_2(1-\omega_1)L + \omega_1(1-\omega_2)U]$$
$$+ \omega_1\omega_2 LU - \lambda(I - \omega_1 L)(I - \omega_2 U)]\}x$$
$$= (I - \omega_2 U)^{-1}(I - \omega_1 L)^{-1}[(1 - \omega_1 - \omega_2 + \omega_1\omega_2 - \lambda)I$$
$$+ (\omega_2 - \omega_1\omega_2 + \lambda\omega_1)L + (\omega_1 - \omega_1\omega_2 + \lambda\omega_2)U + (1-\lambda)\omega_1\omega_2 LU]x$$
$$= (I - \omega_2 U)^{-1}(I - \omega_1 L)^{-1}[(1 - \omega_1 - \omega_2 + \omega_1\omega_2 - \lambda)I$$
$$+ (\omega_2(1 - \omega_1) + \lambda\omega_1)L + (\omega_1(1-\omega_1) + \lambda\omega_2)U + (1-\lambda)\omega_1\omega_2 LU]x$$
$$= (I + \omega_2 U + \omega_2^2 U^2 + \cdots)(I + \omega_1 L + \omega_1^2 L^2 + \cdots)[(1 - \omega_1 - \omega_2 + \omega_1\omega_2 - \lambda)I$$

$$+(\omega_2(1-\omega_1)+\lambda\omega_1)L+(\omega_1(1-\omega_1)+\lambda\omega_2)U+(1-\lambda)\omega_1\omega_2 LU]x$$

It is obvious that

$\omega_2(1-\omega_1)+\lambda\omega_1 \geq 0$ and $\omega_1(1-\omega_1)+\lambda\omega_2 \geq 0$ when $0 \leq \omega_i \leq 1, i=1,2$,

and

$1-\omega_1-\omega_2+\omega_1\omega_2-\lambda \geq 0$ if and only if $\omega_1+\omega_2-\omega_1\omega_2 \leq 1-\lambda$,

so we obtain

$$S_{\omega_1,\omega_2}x-\lambda x \geq 0,$$

i.e.,

$$S_{\omega_1,\omega_2}x \geq \lambda x.$$

Thus, by Lemma 2.2, we have

$$\rho(B) \leq \rho(S_{\omega_1,\omega_2}).$$

Remark From the Theorem 3.1 and Theorem 3.2, we can conclude that in the USSOR iterative method, the choice of parameter ω_1 and ω_2 is very important. If we choose inappropriate, the USSOR iterative method is not better than Jacobi iterative method.

Numerical example

In this section we give a numerical example to illustrate the results obtained in Section 3.

Let us consider the matrix A of (1),

$$A=\begin{bmatrix} 1 & -0.035 & -0.138 & -0.057 & -0.032 \\ -0.155 & 1 & -0.343 & -0.039 & -0.016 \\ -0.134 & -0.173 & 1 & -0.132 & -0.182 \\ -0.346 & -0.208 & -0.031 & 1 & -0.038 \\ -0.072 & -0.006 & -0.329 & -0.292 & 1 \end{bmatrix},$$

and the parameters ω_1, ω_2 according to the conditions imposed in Theorems 3.1 and 3.2, the numerical results are presented in Table 1.

Table 1

ω_1	ω_2	$\rho(B)$	$\rho(S_{\omega_1,\omega_2})$
0.31	0.14	0.5285	0.7830
0.29	0.12	0.5285	0.8019
0.25	0.15	0.5285	0.8095
0.19	0.23	0.5285	0.8015
0.06	0.41	0.5285	0.7063
0.35	0.11	0.5285	0.7739
0.22	0.13	0.5285	0.8334
0.17	0.30	0.5285	0.7758
0.41	0.05	0.5285	0.7628
0.03	0.27	0.5285	0.8506
0.27	0.20	0.5285	0.7773
0.14	0.23	0.5285	0.8242
0.12	0.35	0.5285	0.7706
0.08	0.32	0.5285	0.8031
0.42	0.05	0.5285	0.7569

Remark From the above table, it is easy to know that $\rho(B) \leq \rho(S_{\omega_1,\omega_2})$, so we get that the results are in concord with Theorem 3.1 and Theorem 3.2.

Keywords: IMGS iterative method; Spectral radius; Symmetric positive definite matrix; H-matrix

Abstract. In this paper, in order to improve the convergence rates of iterative method solving the linear system $Ax=b$, the improving modified Gauss-Seidel (IMGS) iterative method with a preconditioner $P_\alpha = I + S_\alpha$ is proposed. Some convergence and comparison results are given when A is a symmetric definite matrix are provided.

Introduction

Consider the following linear system

$$Ax = b, \tag{1}$$

where A is an $n\times n$ matrix is nonsingular, x and b are n-dimensional vectors.

Iterative methods are effective and practical when the matrix A is large and sparse and are studied by many authors (cf., [1-9], etc).

In order to solve system (1) with iterative methods, the coefficient matrix is split into

$$A = M - N, \tag{2}$$

where M is nonsingular.

Then the basic iterative method for solving the linear system (1) is

$$Mx^{(k+1)} = Nx^{(k)} + M^{-1}b, k = 0,1,\cdots, \tag{3}$$

Thus (3) can also be written as

$$x^{(k+1)} = M^{-1}Nx^{(k)} + M^{-1}b, k = 0,1,\cdots, \tag{4}$$

where $M^{-1}N$ is called an iteration matrix of the iterative method (4).

Now, we transform the original linear system (1) into the preconditioned form

$$PAx = Pb, \tag{5}$$

where P is a nonsingular matrix. The corresponding basic iterative scheme is

$$x^{(k+1)} = {M_P}^{-1}N_P x^{(k)} + {M_P}^{-1}Pb, \quad k = 0,1,2,\ldots \tag{6}$$

where $PA = M_P - N_P$ is a splitting of PA and M_P is nonsingular.Clearly $T_P = {M_P}^{-1}N_P$ is the iteration matrix of the iterative method(6).

Rrecently, in [1] a preconditioned Gauss-Seidel method was proposed for H-matrix with $P_\alpha = I + S_\alpha$, where

$$S_\alpha = \begin{bmatrix} 0 & & & -\alpha_1 a_{1,k_1} & \\ 0 & 0 & -\alpha_2 a_{2,k_2} & & \\ \vdots & \vdots & \ddots & & \\ 0 & 0 & \cdots & \ddots & -\alpha_{n-1}a_{n-1,k_{n-1}} \\ 0 & 0 & 0 & \cdots & 0 \end{bmatrix} \tag{7}$$

and $k_i = \min j \in \{j \big| \max_{j(>i)} |a_{ij}|,\ i < n\}$, and $\alpha_i, i = 1,\cdots,n-1$ are nonnegative real numbers.

In this paper, we will discuss the improving modified Gauss-Seidel (IMGS) iterative method with the preconditioner $P_\alpha = I + S_\alpha$ for a symmetric positive matrix.

Preliminarie

For convenience, we shall now briefly explain some of the terminologies used in the next sections. Let $C=(c_{ij})\in \mathrm{R}^{n\times n}$ be an $n\times n$ real matrix. By $\mathrm{diag}(C)$, we denote the $n\times n$ diagonal matrix coinciding in its diagonal with c_{ii}. For $A=(a_{ij}), B=(b_{ij})$, we write $A\geq B$ if $a_{ij}\geq b_{ij}$ holds for all $i,j=1,2,\cdots,n$. Calling A nonnegative if $A\geq 0 (a_{ij}\geq 0; i,j=1,2,\cdots,n)$, we say that $A-B\geq 0$ if and only if $A\geq B$. Given a matrix $A=(a_{ij})$, we define the matrix $|A|=(|a_{ij}|)$ for all $i,j=1,2,\cdots,n$. For a square matrix A, $\rho(A)$ denotes the spectral radius of A.

Definition 2.1 A matrix $A=(a_{ij})$ is called a Z-matrix if $a_{ij}\leq 0$ for $i\neq j$, Z-matrix is a nonsingular M-matrix, if A is nonsingular and $A^{-1}\geq 0$.

Definition 2.2 Let $A=(a_{ij})$ be an $n\times n$ matrix, we call $\langle A\rangle=(\tilde{a}_{ij})$ is comparison matrix if $\tilde{a}_{ij}=|a_{ij}|$ for $i=j$; $\tilde{a}_{ij}=-|a_{ij}|$ for $i\neq j$. If $\langle A\rangle$ is a nonsingular M-matrix, then A is called an H-matrix.

Lemma 2.1 [2] Let A be a Z-matrix. Then the following ststements are equivalent:

(a) A is an M-matrix.

(b) All principal submatrices of A are M-matrices.

(c) All principal minors are positive.

Lemma 2.2 [3] Let A be an H-matrix, then $|A|^{-1}\leq \langle A\rangle^{-1}$.

Lemma 2.3 [4] Let A and B be two $n\times n$ matrices with $0\leq |B|\leq A$.Then $\rho(B)\leq\rho(A)$.

Lemma 2.4 [5] Let $A=I-L-U$ be a Z-matrix. Then

(a) $\rho(T)<\rho(J)<1$ if $\rho(J)<1$,

(b) $\rho(T)>\rho(J)>1$ if $\rho(J)>1$,

(c) $\rho(T)=\rho(J)=1$ if $\rho(J)=1$.

Lemma 2.5 [4] If $A=I-B$ is an H-matrix if and only if $\rho(|B|)<1$, where $\rho(.)$ denotes the spectral radius of a matrix.

Lemma 2.6 [1] Let $A=I-L-U$ is an H-matrix. If $0\leq\alpha_i\leq 1$ for all $1\leq i\leq n-1$, then $\rho(\tilde{T}_\alpha)\leq\rho(\tilde{T})<1$,where $\tilde{T}_\alpha=(I-|D_\alpha|-|L|-|E_\alpha|)^{-1}(|U|-|S_\alpha|+|F_\alpha|+|S_\alpha||U|)$ and $\tilde{T}=(I-|L|)^{-1}|U|$ and D_α, E_α and F_α are the diagonal, strictly lower and upper triangular parts of $S_\alpha L$.

Result and proof

Without loss of generality, let $A=I-L-U$, where I is the identity matrix, $-L$ and $-U$ are strictly lower and upper triangular parts of A, respectively.

For the preconditioner $P_\alpha=I+S_\alpha$, the preconditioned matrix $A_\alpha=(I+S_\alpha)A$ can be written as

$$A_\alpha=I-L-U+S_\alpha-S_\alpha L-S_\alpha U=(I-D_\alpha-L-E_\alpha)-(U-S_\alpha+F_\alpha+S_\alpha U) \tag{8}$$

where D_α, E_α and F_α are the diagonal, strictly lower and upper triangular parts of $S_\alpha L$, respectively.

Then $T_\alpha=L_\alpha^{-1}U_\alpha$, $L_\alpha=I-D_\alpha-L-E_\alpha$ and $U_\alpha=U-S_\alpha+F_\alpha+S_\alpha U$.

Next, some convergence results of the IMGS iterative method for a symmetric positive definite matrix A is provided.

Theorem 3.1 Let $A=I-L-U=$（a_{ij}）be a symmetric positive definite matrix. If $0\leq\alpha_i\leq 1$ for all $1\leq i\leq n-1$, then

$$\rho(T_\alpha)\leq\rho(\tilde{T}_\alpha),$$

where $\tilde{T}_\alpha=\tilde{L}_\alpha^{-1}\tilde{U}_\alpha$, $\tilde{L}_\alpha = I-|D_\alpha|-|L|-|E_\alpha|$, and $\tilde{U}_\alpha=|U|-|S_\alpha|+|F_\alpha|+|S_\alpha||U|$.

Proof Notice that $\langle A\rangle=I-|L|-|U|$ and $\tilde{A}_\alpha=(I+S_\alpha)\langle A\rangle=\tilde{L}_\alpha-\tilde{U}_\alpha$.

Let

$$L_\alpha=(l_{ij}) \text{ and } \tilde{L}_\alpha=(\tilde{l}_{ij}).$$

Then

$$l_{ii}=1-\alpha_i a_{ik_i}a_{k_i i}=1-\alpha_i a_{k_i i}{}^2 \text{ and } \tilde{l}_{ii}=1-\alpha_i\left|a_{ik_i}a_{k_i i}\right|=1-\alpha_i\left|a_{k_i i}\right|^2 \text{ for } 1\le i\le n-1.$$

Since A is a symmetric positive definite matrix, all principal minors of A are positive and so we have

$$1-a_{k_i i}{}^2>0.$$

Since $0\le\alpha_i\le 1$ for all $1\le i\le n-1$, it is easy to see that

$$l_{ii}=1-\alpha_i a_{k_i i}{}^2\ge 1-a_{k_i i}{}^2>0 \text{ for all } 1\le i\le n-1 \text{ and } l_{nn}=\tilde{l}_{nn}=1.$$

From Lemma 2.1 and Definition 2.2, we have $\tilde{L}_\alpha$ is an M-matrix and L_α is an H-matrix(as $\langle L_\alpha\rangle$ is an M-matrix).

It is followed from Lemma 2.2 that

$$|L_\alpha|^{-1}\le\langle L_\alpha\rangle^{-1}. \tag{9}$$

By a simple calculation, it can be shown that

$$\tilde{L}_\alpha{}^{-1}\ge\langle L_\alpha\rangle^{-1}. \tag{10}$$

From (9) and (10), one obtains

$$\tilde{L}_\alpha{}^{-1}\ge|L_\alpha|^{-1}. \tag{11}$$

Since $|U-S_\alpha|=|U|-|S_\alpha|$, we have

$$|U_\alpha|=|U-S_\alpha+F_\alpha+S_\alpha U|\le|U|-|S_\alpha|+|F_\alpha|+|S_\alpha||U|=\tilde{U}_\alpha. \tag{12}$$

From (11) and (12), one obtains

$$|T_\alpha|=|L_\alpha{}^{-1}U_\alpha|\le|L_\alpha|^{-1}|U_\alpha|\le\tilde{L}_\alpha{}^{-1}\tilde{U}_\alpha=\tilde{T}_\alpha.$$

From Lemma 2.3, we can obtain

$$\rho(T_\alpha)\le\rho(\tilde{T}_\alpha).$$

Theorem 3.2 Let the assumption of Theorem 3.1 holds, if $\rho(|L|+|U|)<1$ and $0\le\alpha_i\le 1$ for all $1\le i\le n-1$, then

$$\rho(T_\alpha)\le\rho(\tilde{T}_\alpha)\le\rho(\tilde{T})<1,$$

where $\tilde{T}=(I-|L|)^{-1}U$.

Proof From A is a symmetric positive definite matrix, notice that $\langle A\rangle=I-|L|-|U|$ is a Z-matrix.

Since $\rho(|L|+|U|)<1$, $\rho(\tilde{T})<1$ obtained by applying Lemma 2.4 to $\langle A\rangle$.

As $|L|+|U|=|L+U|$, we have A is an H-matrix from Lemma 2.5.

By applying Lemma 2.6 to A, we obtain

$$\rho(\tilde{T}_\alpha)\le\rho(\tilde{T})<1.$$

Hence, from Therom3.1 we have

$$\rho(T_\alpha)\le\rho(\tilde{T}_\alpha)\le\rho(\tilde{T})<1.$$

Abstract. The cost of all existing algorithm for evaluating n th order determinants is at most $O(n^3)$. This paper presents a new efficient computational algorithm for solving the determinants of the heptadiagonal matrices with cost $O(n)$ only. It is a generalization of the DETGTRI algorithm. The implementation of this algorithm using computer algebra system is straightforward. Numerical examples are given to demonstrate the result.

Introduction

In numerical analysis and numerical calculation, it often generates large amounts of nonsingular sparse matrices. The calculation of these kinds of matrices' determinants are more convenient, because they have some special structures. The banded matrices are very popular among them, especially tri-diagonal matrices [1,3], penta-diagonal matrices [2,4,5,6,7] and heptadiagonal matrices. Many problems in mathematics and applied science require the solution of linear systems having heptadiagonal coefficient matrices. This problem often appear in signal processing, image processing, parallel computing, telecommunication system analysis and solving differential equations using finite differences. When solving the determinants, it only needs seven vectors to store the matrix in the computer, rather than store the remaining zero elements. So it can save the storage space in the computer.

Consider the general tri-diagonal determinant T_0 of order n of the form

$$T_0 = \begin{pmatrix} d_1 & a_1 & 0 & \cdots & \cdots & 0 \\ b_2 & d_2 & a_2 & \ddots & & \vdots \\ 0 & b_3 & d_3 & \ddots & 0 & \vdots \\ \vdots & \ddots & \ddots & \ddots & \ddots & 0 \\ \vdots & & 0 & \ddots & \ddots & a_{n-1} \\ 0 & \cdots & \cdots & 0 & b_n & d_n \end{pmatrix}. \tag{1}$$

A general $n \times n$ tri-diagonal matrix of form (1) can be stored in $3n-2$ memory locations by using three vectors $a=(a_1,a_2,\ldots,a_{n-1})$, $b=(b_2,b_3,\ldots,b_n)$, $d=(d_1,d_2,\ldots,d_n)$. Recently, a computational approach to find the inverse of the general tri-diagonal matrix T_0 in (1) is given in [8]. In [9], it has been shown that it is very useful to introduce an additional $n-$dimensional vector $c=(c_1,c_2,\ldots,c_n)$, by

$$c_i = \begin{cases} d_1 & if \quad i=1 \\ d_i - \dfrac{b_i a_{i-1}}{c_{i-1}} & if \quad i=2,3,\ldots,n \end{cases}. \tag{2}$$

It has been proved that the matrix T_0 is positive definite only if $c_i > 0$ for each $i = 1,2,\ldots,n$. And $\det T_0 = \left(\Pi_{r=1}^{n} c_r\right)$.

For $n \geq 5$, a general heptadiagonal matrix $T = \left(t_{ij}\right)_{1\leq i,\, j\leq n}$ takes the form

$$T = \begin{pmatrix} d_1 & a_1 & a_1^* & \hat{a}_1 & 0 & 0 & 0 & 0 & 0 & 0 \\ b_2 & d_2 & a_2 & a_2^* & \hat{a}_2 & 0 & 0 & 0 & 0 & 0 \\ b_3^* & b_3 & d_3 & a_3 & a_3^* & \hat{a}_3 & 0 & 0 & 0 & 0 \\ \hat{b}_4 & b_4^* & b_4 & d_4 & a_4 & a_4^* & \hat{a}_4 & 0 & 0 & 0 \\ 0 & \hat{b}_5 & b_5^* & b_5 & d_5 & a_5 & a_5^* & \hat{a}_5 & 0 & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & 0 & \hat{b}_{n-3} & b_{n-3}^* & b_{n-3} & d_{n-3} & a_{n-3} & a_{n-3}^* & \hat{a}_{n-3} \\ 0 & 0 & 0 & 0 & \hat{b}_{n-2} & b_{n-2}^* & b_{n-2} & d_{n-2} & a_{n-2} & a_{n-2}^* \\ 0 & 0 & 0 & 0 & 0 & \hat{b}_{n-1} & b_{n-1}^* & b_{n-1} & d_{n-1} & a_{n-1} \\ 0 & 0 & 0 & 0 & 0 & 0 & \hat{b}_n & b_n^* & b_n & d_n \end{pmatrix}. \tag{3}$$

in which $t_{ij} = 0$ for $|i-j| \geq 4$.

A general $n \times n$ heptadiagonal matrix of form (3) can be stored in $7n-12$ memory locations by using seven vectors $d = (d_1, d_2, \ldots, d_n)$, $a = (a_1, a_2, \ldots, a_{n-1})$, $a^* = (a_1^*, a_2^*, \ldots, a_{n-2}^*)$, $\hat{a} = (\hat{a}_1, \hat{a}_2, \ldots, \hat{a}_{n-3})$, $b = (b_2, b_3, \ldots, b_n)$, $b^* = (b_3^*, b_4^*, \ldots, b_n^*)$, $\hat{b} = (\hat{b}_3, \hat{b}_4, \ldots, \hat{b}_n)$. It is better to prove the nonsingularity of the matrix T in (3) before solving the difference equation with variable coefficients.

In this paper, it mainly comes up with an efficient algorithm to compute the n th order determinant of the matrix T in (3) with cost $O(n)$ only. The rest of this paper is organized as follows: in section 2, it gives the algorithm to compute the determinant of the matrix T in (3). In section 3, numerical examples show the performance of the algorithm.

The main results

In this section, it is now time to formulate the result: giving a new algorithm to compute the determinants of any $n \times n$ heptadiagonal matrices of the form (3). Throughout the section and the next sections, the parameter λ is just a symbolic name and $\det T$ is the determinant of the heptadiagonal matrices.

Algorithm: To compute the $\det T$, it may proceed as follows:

Step 1: Set $c_1 = d_1$. If $c_1 = 0$, then $c_1 = \lambda$; Set $e_1 = a_1$;

Step 2: Set $f_2 = \dfrac{b_2}{c_1}$, then $c_2 = d_2 - f_2 e_1$; If $c_2 = 0$, then $c_2 = \lambda$;

Step 3: Set $g_3 = \dfrac{b_3^*}{c_1}$, $x_1 = a_1^*$, $e_2 = a_2 - f_2 x_1$, $f_3 = \dfrac{b_3 - g_3 e_1}{c_2}$, then $c_3 = d_3 - f_3 e_2 - g_3 x_1$; If $c_3 = 0$, then $c_3 = \lambda$;

Step 4: Set $x_2 = a_2^* - f_2 \hat{a}_1$, $x_3 = a_3^* - f_3 \hat{a}_2$; $e_3 = a_3 - f_3 x_2 - g_3 \hat{a}_1$;

For k from 4 to n do

$h_k = \dfrac{\hat{b}_k}{c_{k-3}}$, $l_k = \dfrac{b_k^* - h_k e_{k-3}}{c_{k-2}}$, $m_k = \dfrac{b_k - h_k x_{k-3} - l_k e_{k-2}}{c_{k-1}}$, $e_k = a_k - l_k \hat{a}_{k-2} - m_k \hat{a}_{k-1}$, $x_k = a_k^* - m_k \hat{a}_{k-1}$, then $c_k = d_k - h_k \hat{a}_{k-3} - l_k x_{k-2} - m_k e_{k-1}$; If $c_k = 0$, then $c_k = \lambda$;

Step 5: $\det T = \left(\Pi_{r=1}^{n} c_r\right)\Big|_{\lambda=0}$.

The cost of this algorithm is $O(n)$ only. The algorithm is easy to implement using computer algebra systems such as MACSYMA and MAPLE.

Illustrative examples

In this section, it gives some examples.

Example 1 . Consider the following 6×6 matrix A

$$A = \begin{pmatrix} 1 & 1 & -1 & 1 & 0 & 0 \\ 2 & 1 & 2 & 2 & 3 & 0 \\ 2 & 1 & 2 & 1 & 0 & 1 \\ 1 & 1 & 2 & 0 & 1 & 2 \\ 0 & 2 & 0 & 2 & 1 & 0 \\ 0 & 0 & 1 & 2 & 1 & 1 \end{pmatrix}.$$

We have

$g_3 = 2$

$(f_2, f_3) = (2,1)$

$$(x_1, x_2, x_3, x_4) = \left(-1,0,-3,\frac{2\lambda-3}{\lambda}\right)$$

$$(e_1, e_2, e_3, e_4, e_5) = \left(1,4,-1,\frac{\lambda+9}{\lambda},\frac{-4\lambda-2}{3-\lambda}\right)$$

$$(m_4, m_5, m_6) = \left(\frac{3}{\lambda},\frac{2\lambda+8}{3-\lambda},\frac{-3\lambda-19}{-9\lambda-29}\right)$$

$$(l_4, l_5, l_6) = \left(0,\frac{8}{\lambda},\frac{2\lambda+1}{3-\lambda}\right)$$

$$(h_4, h_5, h_6) = \left(1,-2,\frac{1}{\lambda}\right)$$

$$(c_1, c_2, c_3, c_4, c_5, c_6) = \left(1,-1,\lambda,\frac{\lambda-3}{\lambda},\frac{-9\lambda-29}{3-\lambda},\frac{-33\lambda-90}{-9\lambda-29}\right)$$

Therefore, $\det A = \left(\Pi_{r=1}^{6} c_r\right)\Big|_{\lambda=0} = 90$.

Example 2 . Consider the following 7×7 matrix B

$$B = \begin{pmatrix} 1 & 1 & -1 & 1 & 0 & 0 & 0 \\ 2 & 2 & 2 & 2 & 3 & 0 & 0 \\ 1 & 1 & 2 & 1 & 1 & 1 & 0 \\ 2 & 1 & 2 & 1 & 1 & 2 & 1 \\ 0 & 2 & 1 & 2 & 0 & 1 & 1 \\ 0 & 0 & 1 & 2 & 1 & 1 & 1 \\ 0 & 0 & 0 & 1 & 1 & 1 & 2 \end{pmatrix}.$$

We have

$g_3 = 1$

$(f_2, f_3) = (2,0)$

$(x_1, x_2, x_3, x_4, x_5) = \left(-1,0,1,\frac{2\lambda-4}{3\lambda},3\right)$

$(e_1, e_2, e_3, e_4, e_5, e_6) = \left(1,4,0,\frac{-\lambda+5}{3\lambda},2,\frac{3\lambda+10}{\lambda}\right)$

$(m_4, m_5, m_6, m_7) = \left(\frac{4\lambda+4}{3\lambda},-2,\frac{-10}{3\lambda},\frac{3\lambda+2}{2\lambda+4}\right)$

$(l_4, l_5, l_6, l_7) = \left(\frac{-1}{\lambda},\frac{\lambda-8}{3\lambda},-2,\frac{-2\lambda-5}{3\lambda}\right)$

$(h_4, h_5, h_6, h_7) = \left(2,\frac{2}{\lambda},\frac{1}{3},-1\right)$

$(c_1, c_2, c_3, c_4, c_5, c_6, c_7) = \left(1,\lambda,3,-1,-1,\frac{6\lambda+12}{3\lambda},\frac{\lambda-6}{2\lambda+4}\right)$

Therefore, $\det B = \left(\Pi_{r=1}^{7} c_r\right)\Big|_{\lambda=0} = -18$.

Conclusion

In this paper, it presents a new efficient computational algorithm for solving the determinants of the heptadiagonal matrices with cost $O(n)$ only. Some numerical examples prove that the algorithm works well. Hence, it may become a useful tool for the determinant evaluation.

Keywords: Two-parameter P-NCD conjugate projection gradient method; global convergence; drop analysis

Abstract. On the basis of the conjugate gradient method CD, the artile builds a new two-parameter P-NCD projected conjugate gradient method, the article gives two-parameter P-NCD Conjugate Gradient Method drop projection and on the strong Wolfe line search in the principles of the convergence criteria, the new algorithm is applied to estimate the equation with linear constraints in the model instantiated test ,the results shows good results.

Introduction

The gradient projection algorithm in constrained optimization problem was first proposed by Luo Shen in 1960.Using gradient projection technologies combined with a variety of linear search algorithm is formed, called the gradient projection algorithm.

Two-parameter P-NCD Conjugate Projection Gradient Method

The constrained optimization problem (P):

$$\min_{\beta\in R^p} f(\beta)=\sum_{i=1}^{n}\varepsilon_i^2=\sum_{i=1}^{n}\left(y_i-x_i^T\beta-g(z_i,u_i,\beta)\right)^2$$
$$s.t. \qquad A\beta=b$$

Where $f(\beta)$ is a continuous and differentiable function. the paper uses the improved optimization of the two-parameter P-NCD conjugate gradient method estimatesthe β.

An iterative algorithm for solving constrained optimization problems $\beta^{(k+1)}=\beta^{(k)}+\lambda_k d_k$,inside $\alpha_k^{new}=\dfrac{\|pg_k\|^2}{-\mu g_{k-1}^T d_{k-1}+\nu d_{k-1}^T(g_k-g_{k-1})}$, $\mu\geq 0$, $\nu\geq 0$, $\mu+\nu=1$.

The problem (P) of the K-T conditions[1] $\begin{cases}\nabla f(\beta)+\lambda A^T=0\\ A\beta=b\end{cases}$, λ Lagrange multiplier.

Two-parameter P-NCD conjugate gradient projection algorithm:

Step1: given initial point $\beta^{(1)}=(\beta_1^{(1)},\cdots,\beta_p^{(1)})$,In order to meet the conditions of $A\beta^{(1)}=b$,make $k:=1$, $\beta^{(0)}=0$, $d_0=0$;

Step 2：Calculation Pg_1 ,if $\|Pg_1\|=0$,Stop calculation,The constrained optimization problem of K-T for $\beta^{(1)}$; Or the direction of $d_k=-Pg_k+\alpha_k d_{k-1}$,When the $k>1$ is $\alpha_k^{new}=\dfrac{\|pg_k\|^2}{-\mu g_{k-1}^T d_{k-1}+\nu d_{k-1}^T(g_k-g_{k-1})}$, $\mu\geq 0$, $\nu\geq 0$, $\mu+\nu=1$;

Step 3 ： The step of the λ_k by the strong Wolfe principle,that is $f(x_k+\alpha_k d_k)\leq f(x_k)+\rho\alpha_k g_k^T d_k$ and $\left|d_k^T g(x_k+\alpha_k d_k)\right|\leq -\sigma d_k^T g_k$, $0<\rho<\sigma<1$,make $\beta^{(k+1)}=\beta^{(k)}+\lambda_k d_k$, $f_{k+1}=f\left(\beta^{(k+1)}\right)$, $\beta^{(k+1)}=\beta^{(k)}+\lambda_k d_k$, $f_{k+1}=f\left(\beta^{(k+1)}\right)$,return to step 2.

The decline analysis

Lemma 1 [3] ： The function of $f(\beta)$,if direction of d_1 satisfies the condition $Ad_1 = 0$,direction sequence $\{d_k\}$ according to formula $d_k = -Pg_k + \alpha_k d_{k-1}$ produced to satisfy equation $Ad_k = 0$, $(Pg_k)^T d_k = g_k^T d_k$,

$(Pg_{k+1})^T d_k = g_{k+1}^T d_k$, $\forall k \geq 1$.

Lemma 2[4] ： If the objective function is to satisfy the assumptions,make $\beta^{(k+1)} = \beta^{(k)} + \lambda_k d_k$, d_k satisfy the condition $(Pg_k)^T d_k < 0$,the step size λ_k from strong Wolfe principle,so $\sum_{k\geq 1, d_k \neq 0} \frac{\left((Pg_k)^T d_k\right)^2}{\|d_k\|^2} < +\infty$,this type is called the generalized Zoutendijk condition.

Lemma 3：If $Pg_k \neq 0$,Produced by the new algorithm d_k is a direction of descent direction, That is $(Pg_k)^T d_k = g_k^T d_k < 0$, $\forall k \geq 1$.

Proof : By induction proof. When $k = 1$,has

$$d_1 = -Pg_1,\ g_1^T d_1 = -g_1^T Pg_1 = -g_1^T P^T Pg_1 = -(Pg_1)^T Pg_1 = -\|Pg_1\|^2 < 0$$

When k>1,has $(Pg_{k-1})^T d_{k-1} = g_{k-1}^T d_{k-1} < 0$.

In $d_k = -Pg_k + \alpha_k^{new} d_{k-1}$ with both sides multiplied by $(Pg_k)^T$ has

$$(Pg_k)^T d_k = (Pg_k)^T \left(-Pg_k + \alpha_k^{new} d_{k-1}\right) = -\|Pg_k\|^2 + \alpha_k^{new} (Pg_k)^T d_{k-1}$$

$$= -\|Pg_k\|^2 + \frac{\|pg_k\|^2}{-\mu g_{k-1}^T d_{k-1} + \nu d_{k-1}^T (g_k - g_{k-1})} (Pg_k)^T d_{k-1}$$

$$= \frac{-\mu \|Pg_k\|^2 g_{k-1}^T d_{k-1} - \nu \|Pg_k\|^2 d_{k-1}^T (g_k - g_{k-1}) + \|Pg_k\|^2 g_k^T d_{k-1}}{-\mu g_{k-1}^T d_{k-1} + \nu d_{k-1}^T (g_k - g_{k-1})}$$

$$= \frac{-\mu \|Pg_k\|^2 g_{k-1}^T d_{k-1} - \nu \|Pg_k\|^2 g_k^T d_{k-1} + \nu \|Pg_k\|^2 g_{k-1}^T d_{k-1} + \|Pg_k\|^2 g_k^T d_{k-1}}{-\mu g_{k-1}^T d_{k-1} + \nu d_{k-1}^T (g_k - g_{k-1})}$$

$$= \frac{(\mu+\nu)\|Pg_k\|^2 g_{k-1}^T d_{k-1} - (\nu-1)\|Pg_k\|^2 g_k^T d_{k-1}}{-\mu g_{k-1}^T d_{k-1} + \nu d_{k-1}^T (g_k - g_{k-1})} = \frac{\|Pg_k\|^2 g_{k-1}^T d_{k-1} - (\nu-1)\|Pg_k\|^2 g_k^T d_{k-1}}{-\mu g_{k-1}^T d_{k-1} + \nu d_{k-1}^T (g_k - g_{k-1})}$$

By the stronge Wolfe line search conditions has $-g_k^T d_{k-1} \leq -\sigma g_{k-1}^T d_{k-1}$,so has

$$(Pg_k)^T d_k \leq \frac{\|Pg_k\|^2 g_{k-1}^T d_{k-1} - \sigma(\nu-1)\|Pg_k\|^2 g_{k-1}^T d_{k-1}}{-\mu g_{k-1}^T d_{k-1} + \nu d_{k-1}^T (g_k - g_{k-1})}$$

$$\leq \frac{\|Pg_k\|^2 g_{k-1}^T d_{k-1}\left[1-\sigma(\nu-1)\right]}{(-\mu-\nu) g_{k-1}^T d_{k-1} + \nu d_{k-1}^T g_k} \leq \frac{\|Pg_k\|^2 g_{k-1}^T d_{k-1}\left[1-\sigma(\nu-1)\right]}{-g_{k-1}^T d_{k-1} + \sigma\nu d_{k-1}^T g_{k-1}} \leq \frac{\|Pg_k\|^2 (1-\sigma\nu+\sigma)}{\sigma\nu - 1}$$

Because $\nu \geq 0$, $\mu+\nu=1$, $0 < \sigma < 1$,so $\sigma\nu < 1$, $\sigma\nu - 1 < 0$, $1-\sigma\nu+\sigma > 0$,so $(Pg_k)^T d_k < 0$, the decline was established.

Convergence analysis

Theorem 1:A constrained optimization problem satisfy assumptions,consideration of the new algorithm, the step size λ_k from Wolfe principle,the iteration point is produced by the algorithm of $\{\beta_k\}$,For a number of k, $Pg_k = 0$ type or $\liminf_{k\to\infty} \|Pg_k\| = 0$ type set.

Proof: If the theorem does not hold, then there exists $C>0$,make $\|Pg_k\|^2>C$, $k=1,2\cdots\cdots$ or the ends of formula $d_k+Pg_k=\alpha_k^{new}d_{k-1}$ modulus, square, and then transpose get

$$\|d_k\|^2=\left(\alpha_k^{new}\right)^2\|d_{k-1}\|^2-2\left(Pg_k\right)^T d_k-\|Pg_k\|^2 \tag{1-1}$$

By lemma 3 available $\alpha_k^{new}\le\dfrac{-\left(Pg_k\right)^T d_k\left(1-\sigma\nu\right)}{\left(1-\sigma\nu+\sigma\right)\left(\sigma\nu-1\right)g_{k-1}^T d_{k-1}}=\dfrac{\left(Pg_k\right)^T d_k}{\left(1-\sigma\nu+\sigma\right)g_{k-1}^T d_{k-1}}$

And in the (1-1) with both sides divided by $\left(\left(Pg_k\right)^T d_k\right)^2$

$$\frac{\|d_k\|^2}{\left(\left(Pg_k\right)^T d_k\right)^2}\le\frac{\|d_{k-1}\|^2}{\left[\left(1-\sigma\nu+\sigma\right)g_{k-1}^T d_{k-1}\right]^2}-\frac{2}{\left(Pg_k\right)^T d_k}-\frac{\|Pg_k\|^2}{\left(\left(Pg_k\right)^T d_k\right)^2}$$

$$=\frac{\|d_{k-1}\|^2}{\left[\left(1-\sigma\nu+\sigma\right)g_{k-1}^T d_{k-1}\right]^2}-\left(\frac{1}{\|Pg_k\|}+\frac{\|Pg_k\|}{\left(\left(Pg_k\right)^T d_k\right)}\right)^2+\frac{1}{\|Pg_k\|^2}\le\frac{\|d_{k-1}\|^2}{\left[\left(1-\sigma\nu+\sigma\right)g_{k-1}^T d_{k-1}\right]^2}+\frac{1}{\|Pg_k\|^2}$$

Because $\dfrac{\|d_1\|^2}{\left(\left(Pg_1\right)^T d_1\right)^2}=\dfrac{1}{\|Pg_1\|^2}$,so from the above formula can be obtains

$$\frac{\|d_k\|^2}{\left(\left(Pg_k\right)^T d_k\right)^2}\le\frac{1}{\left(1-\sigma\nu+\sigma\right)^2}\frac{1}{\|Pg_1\|^2}+\sum_{i=2}^{k}\frac{1}{\|Pg_i\|^2}\le\frac{1}{\left(1-\sigma\nu+\sigma\right)^2}\frac{1}{C}+\sum_{i=2}^{k}\frac{1}{\|Pg_i\|^2}$$

Because $\left(1-\sigma\nu+\sigma\right)^2>1$,then $\dfrac{\|d_k\|^2}{\left(\left(Pg_k\right)^T d_k\right)^2}\le\dfrac{1}{C}+\dfrac{K-1}{C}=\dfrac{K}{C}$, has $\dfrac{\left(\left(Pg_k\right)^T d_k\right)^2}{\|d_k\|^2}\ge\dfrac{C}{K}$, so has

$\sum_{k=1}^{\infty}\dfrac{\left(\left(Pg_k\right)^T d_k\right)^2}{\|d_k\|^2}=+\infty$,his lemma conclusion 2 contradictions, the assumption does not hold, so has $\liminf_{k\to\infty}\|Pg_k\|=0$.

The example analysis

The following examples evaluate two-parameter P-NCD validity projection conjugate gradient method.Using the least squares method for the linear model under conditions of equality constraints to estimate the parameters β, the model is $y_i=x_1\beta_1+x_2\beta_2+x_3\beta_3+x_4\beta_4+x_5\beta_5+x_6\beta_6+\varepsilon_i$,solution was to $\beta=\left(0.038,0.353,0.121,0.286,-0.064,0.273\right)^T$,using the double parameter P-NCD conjugate gradient projection method is proposed in this paper, through the MATLAB software iterative calculation, the $\beta'=\left(0.034,0.350,0.19,0.27,-0.059\right)^T$,the equality constraints is $A\beta=b$,among them

$$A=\begin{pmatrix}a_1\\a_2\end{pmatrix}=\begin{pmatrix}2&6&7&4&1&3\\1&2&4&7&8&9\end{pmatrix},b=\begin{pmatrix}b_1\\b_2\end{pmatrix}=\begin{pmatrix}4.12\\3.21\end{pmatrix}$$

Table 1 Sample points

No.	x_1	x_2	x_3	x_4	x_5	x_6	y_i
1	100	100	100	100	100	100	100
2	10.15	72.25	100	100	100	100	85
3	0	0	87.5	98.4	94.7	100	60
4	0	0	32.8	65.55	88.4	100	45
5	0	0	27.3	52.45	86.8	100	37

Keywords: Generalized J sets; Frieze group; Escape-time algorithm;

Abstract. The paper introduces escape-time algorithm applied to construct G-J set firstly, and two methods are presented for generating a great diversity of generalized J sets in which the point fall in low-cycle attract collections in the domain. One of the coloring methods is according to attract time, another is by recording the domain of the orbits. We used frieze group map to validate effectiveness for algorithm.

Introduction

Chaos theory is a field of study in mathematics, it has received a great deal of interest among scientists from various fields such as meteorology, physics, engineering, economics,biology, and philosophy[1]. An early proponent of chaos theory was Henri Poincaré. In the 1880s, while studying the three-body problem, he found that there can be orbits that are nonperiodic, and yet not forever increasing nor approaching a fixed point [2]. Till now, many chaotic mappings have been proposed. Recognizing that chaos and fractal patterns have huge potential applications in architectural decoration, advertising and other fields, chaos graphics visualization has become a hot research issue [3]. In [4], some chaos visualization methods have been proposed based on constructing M sets. In [5], many strange attractor icons with symmetric feature have been designed. After French mathematician Gaston Julia computing a Julia set by computer, constructing Jualia graphics become an effective scheme for chaos visualization. In [6-7], some chaos and tilings mapping models have been disigned, but how to construct Julia set of this kind of models is not investigated. Based on the M-J theory and the period orbits of the systems, this paper give two algorithms to construct the generalized Julia sets, experiments show that the method is effective.

Constructing generalized J set of frieze group with the escape time algorithm.

Complex plane on track bounded set of points called J set, the structure of the classic with J sets usually adopt the escape time algorithm, namely the utility plane orbit initial point bounded points with unbounded initial orbit, on a computer screen with different colors to distinguish.Escape time algorithm is an effective and has a profound theoretical background map fractal method, all kinds of full of J and M sets can be drawn by this method.In this paper, the author studies on Frieze group of equivalence, the along the axis cycle for translational symmetry characteristics, there are no restrictions on the direction, therefore, can escape time algorithm to generate the mapping of the generalized with Julia set.

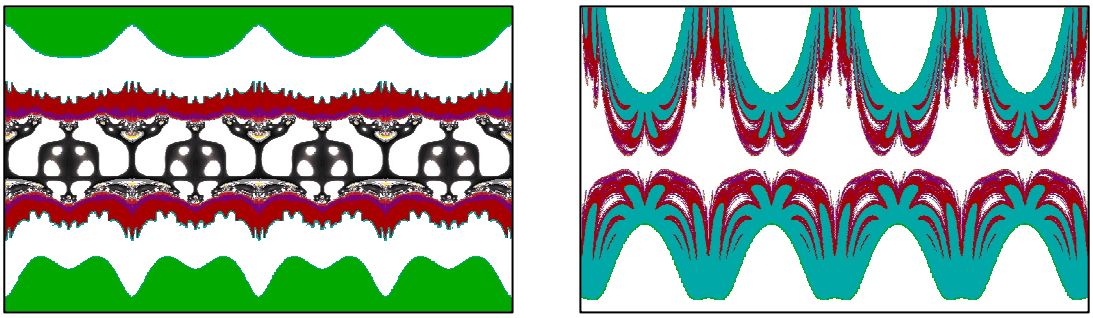
Set $A=\{\, x\in X\in Z:\ f^k(z)\in X, k=1,2,\cdots\}$, is Frieze all orbit in the group of mapping of bounded point set, choose the direction of the radius of the escape, so in the process of iteration, according to the point of the rail ran out of the radius of the number of iterations for coloring, then can form rich color graphics, concrete implementation steps of the algorithm are as follows:

- Take maximum number of iterations N, iterative area W, a computer screen representing escape radius R;
- Define the elapsed time functions：

$$T(z)=\begin{cases} k, |f^k(z)|\geq R, |f^i(z)|< R, i=1,2,\cdots,k-1, k\leq N \\ \\ 0, f^i(z)|< R, i=1,2,\cdots,N \end{cases}$$

- Confirm the point z of iterative area ,calculate $T(z)$;
- If $T(z)=0, z\in A$, else $T(z)\neq 0, z\notin A$;
- Color the point z according to the escape time function;

Fig 1(a) (b) is generated in the escape time model pm11 generalized J set graphics, white areas represent the point sets complex plane not escaping, namely real generalized filled J set. Color is the elapsed time at every point, Fig1 (a) is generated by the parameters of vector $\boldsymbol{a}'=\{\, a_i,\ i=1,2\cdots 15\,\}$ $=(0.33,0.184,-0.068,0.829,-0.027,-0.753,\ -0.306,\ -0.105,\ 0.599,$ $0.759,-0.106,-0.143,0.226,\ \ 0.269,-0.085)^T$, Fig1(b) is the parameter vector $\boldsymbol{b}=\{\, b_j, j=1,2\cdots 14\,\}=(-0.905,0.3,-0.97,0.643,$ $0.875,0.519,0.919,-0.332,\ 0.733,-0.865,-0.47,-0.647,0.439,-0.217,0.14)^T$.



(a) (b)

Fig.1 The generalized J set created by escape time algorithm

In generalized M sets on regional blue cycle to retrieve any parameters, plane in its power to attract every initial point in the domain are attracted to the article limited periodic orbit. Escape time algorithm is separate escape region and attract region, and use this algorithm to generate generalized with Julia on regional color according to the elapsed time coloring, none of these graphics attraction domain, the nature of the periodic orbit. Filled with two kinds of structure of generalized J sets is proposed in this paper, the method of generalized full of Julia set is generated power plane on track to fall to attract in the domain of the low cycle collection z_0, which attract time algorithm is according to the low cycle track domain point fall in low cycle time on the tracks on the computer screen iterative area of the shaded, attract track algorithm is based on periodic orbit in power will attract domain in the plane of the power effectively differentiate to construct the generalized plane full of Julia set.

Test cycle track.

Frieze group mapping on the horizontal axis has a cycle for translation features, after the experiment found that the longitudinal axis coordinate change near the horizontal axis, so when looking for a power system contains cycle track, you can pick and choose the power plane in a rectangular cell area point as the initial iteration point.In testing a periodic orbit of power system, because the article number, it is impossible to determine the periodic orbit in advance can't determine the orbital cycles, each cycle and for each from the generalized M-set selection on regional cycle parameters of power system cycle track is different, so if using a static two-dimensional array to record the cycle track, will waste a lot of storage space.This article USES the dynamic linked list describes periodic orbit, temporary open cycle list contact storage space, reasonable arrangement of the storage space, and improves the search speed of secondary traversal.

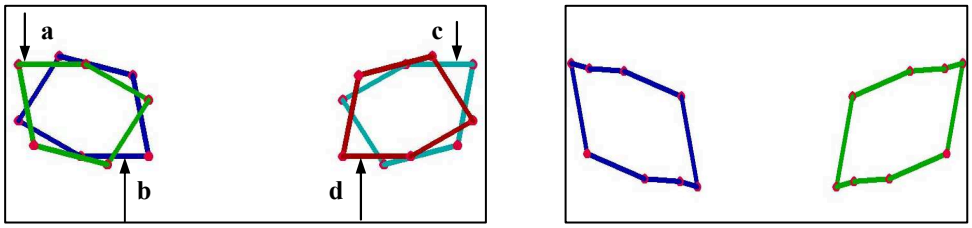


Fig.2 Cycle track diagram of the power system

Fig2 is for the same model of the same parameter section on different cycle parameters of periodic orbit for power system is formed, the letters in the graph represent different cycle track, dot said cycle cycle point on the orbit, orbital diagram separately in a closed orbits of each color lines, said the number of points per line indicates that the cycle track number of cycles.Fig2 (a) (b) from the parameters of the model pma2 section on the generalized M-set ($a_2 \in [-5.0, 5.0]$, $a_5 \in [-3.75, 3.75]$,

Fixed parameters, $a_1 = 0.7052$, $a_3 = -0.5054$, $a_4 = -0.5476$, , $a_6 = 0.3564$, $a_7 = -0.8298$), of different period in the area to select the parameters 1 (0.55155, 0.55155), 2 (0.32491, 0.32491) in the identified cycle track diagram of the power system. Fig 2 (a) of the communist party of China has four five cycle track, and Fig2(b) of the communist party of China has 2 8 periodic orbit. The above results show that the same parameters of cross section of the generalized M set cycle parameters determine the dynamic system of the area of the periodic orbit on the difference of the number and distribution with the parameter position changing.

Two algorithm for generating generalized J set.

In [8] in detail this vector by monte carlo search parameters, attract cycle algorithm and attract track algorithms are used to generate frieze group general train of thought and main implementation steps to implement the Julia set, Fig 3 is the parameters of the model of pm11 section in the generalized M set ($a_1 \in [-10.0, 10.0]$, $a_{13} \in [-7.5, 7.5]$) , fixed parameter of $a_2 = 0.18$, $a_3 = -0.07$, $a_4 = 0.82$, $a_5 = -0.03$, $a_6 = 0.76$, $a_7 = 0.31$, $a_8 = -0.61$, $a_9 = 0.59$, $a_{10} = 0.75$, $a_{11} = 0.11$, $a_{12} = -0.15$, $a_{14} = 0.26$, $a_{15} = 0.09$, Two algorithms above to generate the generalized full of Julia set, the parameters of the point 1 (- 2.14076.0.4791) power system a total of 3 2 cycle track, the two kinds of generalized full of Julia set as shown in Fig3 (a) (c), the parameter point 2 (1.5152.0.0293) of power systems with a total of 2 7 cycle track, the two kinds of generalized full of Julia set as shown in Fig 3 (b) (d).

Fig.4 Generalized full of Julia set and its periodic orbit

Conclusions

This paper introduce two new algorithms to contruct the general Julila sets, the dynamic planar regionthe of the frieze group with fixed cycle parameters was divided, an escape time algorithm was used. Based on the attracting time and attracting orbit, the coloring methods are proposed. The distribution of the system's periodic orbit was analysised. Experiments results show that if we choose different parameters on the cross-section area, the period orbits alway have different number and distribuition, which lead to different structure of the general Julia sets.

Static Fault-Tolerant Strategy for High Performance Computing Platform

Yu Sun, Jun Liu*

School of Computer and Electronics and Information, Guangxi University, Nanning 530004, PR China

E-mail: sunyu1225@163.com liujunzky@163.com

Keywords: High-performance computing platform, Task scheduling strategy, Fault-tolerant model, distributing computing

Abstract. It is an important research issue to ensure the computation correctness for parallel application and enhance the using rate of dynamic computing resource in distributed computing system. Based on the previous high performance distributing computing system, a fault-tolerant and task scheduler was developed, which combined the breathe mechanism, fault-discover mechanism and subtask reschedule mechanism. Experiments show that the fault-tolerant and task-scheduler has good performance and ensures the computation correctness even if when some computing resources fail.

Introduction

High-performance computing runs a broad range of system, from our desktop computers through large parallel processing system. In high-performance computing system, computing nodes will join in or drop out of the system. Meanwhile, the increased number of computing nodes leads to an increased failure rate. The crash of nodes or the nodes' quitting will make the mistake in the computing, and lead the computing system to calculate the application from begin. In the worst condition, the failure nodes will cause the system breaking down. In order to increase the reliability and accuracy of high-performance computing system, we improve the proposed high-performance computing system-WPHPC[3] with a fault-tolerance model.

The rest of this paper is organized as follows. In section 2, we introduce the proposed fault-tolerance High-performance system running on the ProActive, to computing the problem parallel. After that, section 3 presents the typical application, and analyzes and evaluates the results, comparing them to the simple High-performance system without fault-tolerance proposed before. Finally, we conclude and give some future research lines in Section 4.

Fault-Tolerance and Scheduling Algorithm

1.1 Fault-tolerance Algorithm

Given a computing task is divided into m subtasks, and executing on n nodes in the FT-WPHPC. There is the same subtask of every subtask as a backup item. To illustrate the task dispatch model, the details are express as follow. If there are n nodes in the parallel computing system, and we represent the nodes available as the set $N = \{N_1, N_2, \cdots N_n\}$. Each node Ni will be defined as $N_i = \{C_i, T_i, UN_T_i\}$, which Ci stands for the computation capacity, $Task_i = \{ST_\alpha, ST_\beta, \cdots ST_\gamma,\}$ stands for the overall subtasks distributed to the node Ni, and $UN_Task_i = \{UN_ST_\alpha, UN_ST_\beta, \cdots UN_ST_\gamma,\}$ stands for the unfinished subtasks. Subtasks distributed to every node are independent and the amount of subtasks to every node is allocated equally. Every subtasks ST_α will be define as $ST_\alpha = \{ST_M_\alpha, ST_BK_\alpha\}$, which refers the subtask and its bake subtask.If the fault-tolerance server detects the nodes failure to connect and execute the subtasks, it will report the failure node ID to the scheduler, and update the list of available nodes. When scheduler received the failure report, it will dispatch the back of subtasks to other nodes. The fault-tolerance scheduling strategy is as the original scheduling strategy. In this paper, static fault-tolerance scheduling strategy is mainly represented in our scheduling model.

Static fault-tolerance scheduling strategy dispatched subtasks on the basis of the calculated performance of each node. Given the number of nodes is n, the number of subtasks is m, the subtasks dispatched on node i is described as Equation 1.

$$Task_i = \left\lceil \frac{m}{\sum_1^n (c_i)} C_i \right\rceil \quad (1)$$

Where C_i is the calculate performance, which is evaluated by Nbench testing software.

Every checkpoint minutes TTL, server will send hello message to nodes to detect the node is normal or not. The checkpoint minutes TTL is defined as Equation 2 . If fault-tolerance server didn't receive the breath information, the computation node will be considered to become invalid.

$$\mathrm{TTL} = \frac{T}{max\left(len(Task_i)\right)} \quad (2)$$

If node j break down, scheduler will redispatch the unfinished subtask in node j to other nodes in good condition. Scheduler will redispatch the back-up item of the subtask to the node of the lower usage rate, and the back-up item will be executed from the latest record. If node j crashed, the subtask R_ST_i redipatched to node i is as Equation 3.

$$R_ST_i = \left\lceil \frac{UN_ST_j}{\sum_1^n \left(\frac{1}{F_ST_i}\right)} \cdot \frac{1}{F_ST_i} \right\rceil \quad (3)$$

Where, F_ST_i is execution time of first task dispatch in the node i , and UN_ST_j is the unfinished subtask of node j. The fault-tolerance algorithm in detail is presented in Alg.1.

Alg.1 Static Fault-tolerant and Task-scheduling Algorithm

Step1: Collect the calculated performance of computation nodes
Step2: Divide the task submitted into several subtasks, according to Equ. 2, and generate schedule files.
Step 3: According to schedule files, dispatch the subtasks to computation nodes
Step 4: WHILE tasks are not finished DO
    Step 4.1: IF Node i break down
        Step 4.1.1: Adjust the number of unfinished subtask
        Step 4.1.2:Obtain the bake-up item of unfinished subtasks UN_ST_j
        Step 4.1.3:Create active object of bake-up item
        Step 4.1.4:Update the list of available nodes
        Step 4.1.5:According to Equ. 3, redispatch the unfinished subtasks.
    END IF
END WHILE
Step 5:Computation nodes executed subtasks
Step 6:If all of the subtasks are executed
    Step 6.1:Gather and assemble the result
END IF

Experiment

To test the performance of fault-tolerance model, we apply the test function Matrix Multiply on the SFT-WPHPC which is compose of the static fault tolerance strategy and the WPHPC which is without fault tolerance we proposed before . The test function contain two 420*420 matrix to multiply. The FT-WPHPC is compose of 1-11 computation nodes. Computation performance is estimated by testing software Nbench. The parameters of computation nodes are described in Table 1.

Table 1. Parameters of nodes

Node	Nbench	CPU /GHZ	Memory /MB
A	5.975	2	512
B	9.493	2.4	512
C	9.600	2.4	512
D	9.539	2.4	512
E	9.496	2.4	512
F	9.527	2.4	512
G	9.647	2.8	512
H	9.596	2.8	512
I	9.572	2.8	512
J	9.579	2.8	512
K	9.764	2.4	512

To test the cost of the breath mechanism, we execute the 420*420 matric multiply application in the WPHPC and SFT-WPHPC. The application is divided into 30 subtasks.

1.2 Results and Analysis

(1) The cost of fault-tolerance model.

We will compare the execution time of WPHPC and SFT-WPHPC to obtain the cost of fault-tolerance model. The comparison is shown as Fig 3. In the figure, TWPHPC(n) and TWPHPC(n-1) stands for the execution time of the N nodes or N-1 nodes in WPHPC.TsFT-WPHPC(n) described the execution time of SFT-WPHPC system of n nodes when one node break down.

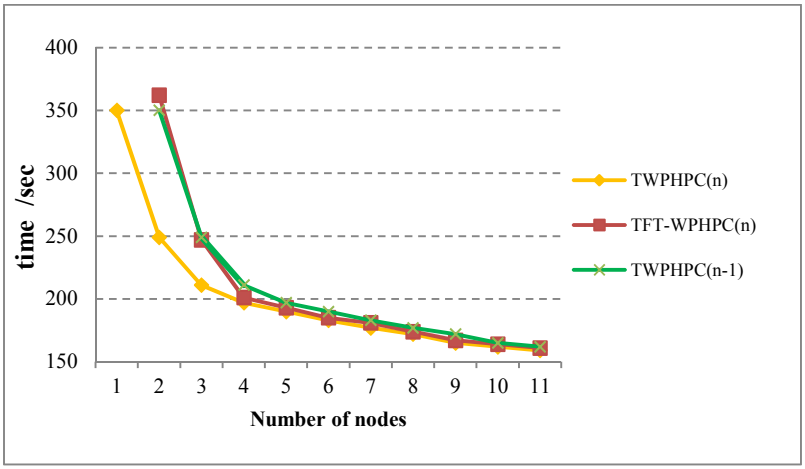

Fig. 1. Comparison of Static Fault-tolerance Model

From Fig.1, the fault-tolerance model guarantees the distributing system work in good condition. If some nodes break down, the model will redispatch the unfinished tasks to other computation nodes, and the execution time is better or equal to the time of WPHPC which contains (n-1) nodes. In the conclusion, the fault tolerance costs little but enhance the reliability of high performance computing system.

Summary

In order to guaranteed fault-tolerance and security of the distributed system, we proposed a new fault-tolerant scheduling model, which contain breath mechanism, failure detection technic and fault diagnosis and subtask restoration strategy, to improve the high perfomance distributed computing system. The experiments illustrated that the new fault-tolerant scheduling model occupies few computing resources to improve the reliability of the system. The system safety is

indispensable for the high performance computing platform, so we will discuss the security mechanism in the future .

Keywords: BP Neural Network, Mine Water Inflow, Prediction Model.

Abstract. Based on predictions of the mine inflow of water and the complexity of influential factors, a method of BP neural network is put forward for mine inrush water prediction in this paper. We chose proper impact factors and establish non-linear artificial neural network prediction model after analyzed the impact factors of mine water inflow in Shandong Heiwang iron, and also made one prediction with normal mine water inflow during the iron mining operation. It turned out that the result can match with the actual prediction data, which make it possible to predict the mine water inflow with the prediction of Artificial Neural Network.

With so many impact factors that affect the mine water inflow and it's hard to make out every impact factor exactly, the prediction of mine water inflow is a job that is complex and practical. So far, it still in under the level of applying Random mathematics and Deterministic mathematical methods approximate calculation. Traditionally deterministic inflow calculation methods mainly include analytical method, numerical method, the water balance method, etc.; Non-deterministic mathematical methods include experience method, regression method, fuzzy math, gray forecasting and timing analysis method[1].Due to the complexity of groundwater system and each calculation methods apply to different condition because of the their own shortcomings. It's an important significance to apply one new method to predict mine water inflow [2].

Artificial Neural Network (ANN) simulates the structure and functions of biological neural network through engineer technology application and computer. Linked with number of artificial networks that similar with natural nervous cells, it's one artificial intelligence system that can process distributed knowledge parallel[1][2][3]. Now the most widely used model is the error back-propagation neural network model – BP model, which can give a better result. BP model is typical one-way and multi-layered feedforward mode, which can be able to learn large mapping relationships, needless to describe the input-output mapping with extra mathematical knowledge. Compared with other models, BP model has the apparent advantage with better durability and timely predictability.

In this paper, we design BP model based on artificial neural network theory, which can predict the mine water inflow and turned to a good result with validation of measured data.

1 .The Structure and Algorithm of BP- Network

1.1..Neuronal structure and mathematical models

Neural networks are widely interconnected by a large number of neurons. Neural networks are divided into two parts according to the connection ways: no-feedforward network and combined network. BP network which is short for feedforward network that made up from non-linear transformation units turned out to be the most widely used one among popular ANN models.

The transportation of BP network is a non-linear function, where the input and output can meet the non-linear monotonically increasing. As f(u) is continuously differentiable, the function can be solved by using gradient algorithm. In addition, the learning algorithm can be called back-propagation

algorithm as its weight analysis is quite clear. In BP network, each neuron receives the inputs from the previous level and outputs to the next stage with no feedback. Figure1. The nodes are divided into input nodes and computing nodes. Each computing unite consists of any inputs with only one output which can be coupled to the input of any other nodes. The input of the i-layer is only linked with the output of (i-1)-layer. The input nodes are considered to be the first layer. Input nodes and output nodes are considered to be visible layers as they are link to outside and can be influenced by environment directly. Other middle layers are called as hidden layers.

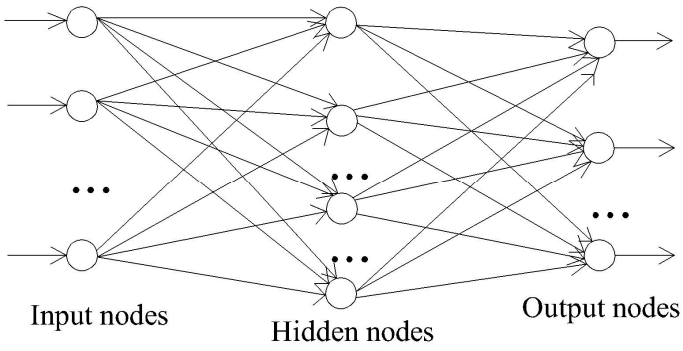

Fig.1 BP network schematic diagram

1.2 BP algorithm

The mathematical expression of BP network is:

$$\begin{cases} s_j = \sum_{i=1}^{n} w_{ij} x_i - \theta_j & (a) \\ u = s_j & (b) \\ y_j = f(u_j) = \dfrac{1}{1+e^{-(\sum_{i=1}^{n} w_{ij} x_j - \theta_j)}} & (c) \end{cases} \tag{1}$$

BP network structure can be divided into three layers: input layer, hidden layer and output layer. And full connections are used among layers and the output of all nodes meets the following requirements.

$$\begin{cases} y_k = f(\sum_{j=0}^{n_1-1} w'_{jk} x'_j - \theta'_k) & k = 0, \cdots m-1 \\ x'_j = f(\sum_{i=0}^{n-1} w_{ij} x_i - \theta_j) & j = 0, \cdots n_1 - 1 \end{cases} \tag{2}$$

And the function of nodes is S (Sigmoid) function; Parameters in (1)-(2) are defined as below:

$\mathbf{x} \in R^n$, $\mathbf{x} = (x_0, x_1, \cdots x_{n-1})^T$ is the input vector of the first layer;

$\mathbf{y} = (y_0, y_1, \cdots y_{m-1})^T$ is the input vector of the third layer;

$\mathbf{x}' = (x'_0, x'_1, \cdots x'_{n_1-1})^T$ is the input vector of the second layer;

The weight between the first layer and the second layer is w_{ij} $(i = 0, \cdots n-1, j = 0, \cdots n_1 - 1)$, the threshold is θ_j $(j = 0, \cdots n_1 - 1)$, the weight between the second layer and the third layer is w'_{jk} $(j = 0, \cdots n_1 - 1, k = 0, \cdots m-1)$, the threshold is θ'_k $(k = 0, \cdots m-1)$.

The specific process of B-P neural algorithm is as follows:

①First of all, set a random number among weight and threshold of all layers as the initial value;

②Input $\mathbf{x}^{p_1}$ （p_1 =1,2…p） by order, and output $y_k^{p_1}$ p_1 =1,2…p, k=0,1…m

③ Calculate the total error between actual output and expected output:

$$E_{p_1} = \frac{1}{2}\sum_{k=0}^{m}(t_k^{p_1} - y_k^{p_1})^2 \tag{3}$$

Given beforehand ε>0, the calculation can end up with E_T<ε; If E_T>ε, amend the weight w_{sq} to make ΔE_T($\Delta E_T$is the change mount of total error) change toward to the decrease direction, and get the result

$$E_T = E(W_{sq}) = E(w'_{jk}, w_{ij}) \tag{4}$$

So, in order to make A always change toward to minimum value, the change should be along with negative gradient direction of E_T. The parameters in (3) (4) are defined as follows:

The expected output of $\boldsymbol{p}$ samples $\mathbf{x}^1, \mathbf{x}^2, \cdots \mathbf{x}^p$ is $\mathbf{t}^1, \mathbf{t}^2, \cdots \mathbf{t}^p$, BP algorithm amend the values of weight and threshold with the error between the actual output $\mathbf{y}^1, \mathbf{y}^2, \cdots \mathbf{y}^p$ and the expected output $\mathbf{t}^1, \mathbf{t}^2, \cdots \mathbf{t}^p$, making $\mathbf{y}^{\mathbf{p_1}}$ and $\mathbf{t}^{\mathbf{p_1}}$ close to each other.

④ Amend the value of weight

In this paper, the weight expression can be as below after amending the value of η^{n_0}:

$$\begin{cases} w'_{jk}(n_0+1) = w'_{jk}(n_0) + \eta^{n_0}\sum_{p_1=1}^{p}\delta_{jk}^{p_1} x'^{p_1}_j \\ w_{ij}(n_0+1) = w_{ij}(n_0) + \eta^{n_0}\sum_{p_1=1}^{p}\delta_{ij}^{p_1} x_i^{p_1} \end{cases} \tag{5}$$

Parameters in (5): let n_0 be number of corrections (iterations), and η^{n_0} be the step size of the n_0 correction (Iteration step size), then we can get the correction values of w'_{jk}, w_{ij} in the n_0+1 correction.

⑤ Convergence criteria, input corrected weight W_{sq}(n_0+1) and get the values of outputs of each layer $x'^{p_1}_j$, $y_k^{p_1}$ (p_1=1,2…p)and E_T. According to the requirements, if all p_1 and k meet $\left|t_k^{p_1} - y_k^{p_1}\right| < \varepsilon$, the finished. Otherwise, correct the value of w_{sq} until meet the requirements. B-P algorithm can be divided into two parts: the first part (Forward propagation), input the message into input layer, proceed in hidden layer to calculate the actual outputs of each units; the second part (Back-propagation), if we can't get expected outputs in the output layer, then we need calculated the error between actual outputs and expected, and then correct the value of the weights according to the value of error to reach the minimum of error value. Two parts process alternately until the convergence is reached. See BP network algorithm structure in Figure 2.

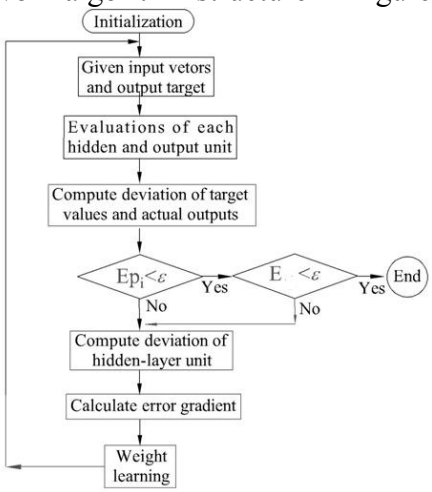

Fig.2. BP network algorithm structure

1.3 The improvement of BP algorithm

Actually, the standard BP algorithm is a simple steepest descent method static optimization, its weight correction formula can be written as a unified:

$$\Delta \mathbf{W}(n) = -\eta \frac{\partial \mathbf{E}}{\partial \mathbf{W}(n)} \tag{6}$$

(6)And here: $\Delta \mathbf{W}(n) = \mathbf{W}(n+1) - \mathbf{W}(n)$, n= 0,1,……is learning iterations.

The optimization direction of above algorithm just along with the gradient direction, the initial value of error function select may be local minimum, but cannot reach to be the global minimum. The convergence speed can be very low gradient algorithm process convergence only once. In order to speed the learning of network, errors, overcome local minimal and speed convergence, domestic and foreign exports have proposed a variety of improvements, including: variable step size method, conjugate gradient method, simulated annealing, genetic algorithms.

1.4 The design of BP network

Input and output layer, the dimension of input and output layer in BP network are totally designed according to the requirement of users.

The I/O relationship in BP network can be viewed as a mapping relationship and one highly nonlinear mapping; the capability of information processing comes from the complexity overlapping of many simple nonlinear functions.

Generally, the number of hidden layer units is based on experience in the network design. While the nodes in input layer and output layer are determined by the nature of the problem. We use construction method and delete method. The so-called construction method is started with a smaller network and it achieves the required performance targets by adding network nodes or neurons in the hidden layer. Contrary, delete method starts with larger network, delete and merge neurons according certain rules to achieve network structure that is suitable for the problem.

The initial values selection. Generally, initial weights are random numbers and relatively small ones, which can ensure neuron a fall start converting them the largest regional function of the rate of change, to prevent a start falling flat area. To eliminate the factors as dimensions and units difference, the input samples are normalized to processing, so that the relatively large inputs can still lag at the larger area of neurons transfer function.

Normalized formula is as blow:

$$x_i = \frac{x_i - x_{\min}}{x_{\max} - x_{\min}} \tag{7}$$

In the formula, x_{max}, x_{min} stands for the maximum value and minimum value in the i-th factors of samples. Factors are mapped to [0, 1] after the conversion.

2. The Calculation of Mine Water Inflow Prediction

2.1 The analysis of geological background and main influence factors

Take Shandong Heiwang iron as example; make prediction calculation of mine water flow with B-P network. The mines are located in East synclinal region of Zibo, which is on the fault zone of the Zihe. Deposit is hosted in fractured Ordovician karst limestone and multiple tectonic activities controlled by fault Zihe Valley, and belong to karst deposits with complex hydrogeological and large water. Zihe is a lager river in this area. After the year 1972, Taihe reservoir was built to reserve water at the location of 15 km upstream at the mine. The area of Taihe reservoir is 780km^2, and it controlled the vast majority of mining upstream drainage area. Large area of limestone outcrop and the Zihe Valley gravel was deposited directly to accept meteoric recharge. In the natural state, the flowing of groundwater, which is along the direction of Zihe Valley from southwest to northeast, will discharge in the form of springs at the contact of the Ordovician and Carboniferous and other relatively impermeable layers. Under the influence of artificial factors, groundwater empties into mining pits and discharges in the form of mine drainage.

From the above analysis of hydrogeological conditions, precipitation is a major source of water gushing in the pit. In addition, the Zihe River flow away from the south and east of the pit, away from the nearest point of the pit is only 50m. The Zihe is the only mine surface water drainage channels.

Since 1972, Taihe reservoir was built and reserved water, and discharged water into Zihe because of the limited reservoir capacity. As good permeability riverbed gravel layer directly overlying fractured limestone karst aquifer above the former indirect deposits roof, which constitute rock, therefore reservoir water drainage impact greatly on the pit. So atmospheric precipitation, rivers Zihe, the river reservoir water have obvious effect for mine drainage.

2.2 Predict the mine water flow with the B-P network model.

1. The design of the network

It used three layers BP network, the first layer is input layer, the second layer is hidden layer and the third layer is output layer.

2. Input and output

According to the hydrogeological conditions of the mine, make the measured data from January – December in 1972 as the sample. In the month precipitation (mm), the month pit water inflow (10^4m^3), the month too River Reservoir release of water (10^4m^3), as input variables of the month next month (March), mine water inflow next month as the output variable (predictor) (10^4 m^3).

Input vector set, $\mathbf{x} \in R^4 \quad \mathbf{x} = \{x_0, x_1, x_2, x_3\}$, x0 = {month rainfall}, x_1 = {month to River Reservoir release of water}, x_2 = {month mine water inflow}, x_3 = {June} month; output vector set $\mathbf{y} \in R^1, \quad \mathbf{y} = \{y\}$, y = {month mine water inflow}.

3. The selection of the nodes

Here the number from hidden layer is 6.

4. Algorithm

Based on gradient algorithm, we select variable step size, plus γ factor items and conjugate gradient method joint learning algorithm for computing.

5. Convergence criteria

The total error convergence criteria is $E_T < \varepsilon$, $\varepsilon < 0.01$.

6. The results

After a certain number of iterations, the gradient algorithm and conjugate gradient algorithm can meet the required error. While, conjugate gradient algorithm converges faster than the gradient algorithm multiple, and can achieve higher requirements, As can be seen from Table 1, for the same number of iterations, conjugate gradient algorithm for error is smaller, even no-processed samples can also generate ideal outputs. Predict the mine water flow for the year of 1972 with the proposed model; we can see that, the predicted data and measured data can achieve a better match. For example: in May 1973, Measured mine water inflow is 559,600 m^3, calculated output is 588,100 m^3. 1972 September measured mine water inflow is 3,283,600 m^3, calculated output is 3,154,100 m^3. Due to the local minima of the gradient algorithm, the initial values should be proper ones in order to reach the global minimum quickly. See the conjugate gradient algorithm output fitting in Figure 3.

Table1. BP Network Training Results

Date	Output of the gradient algorithm (10^4m^3)	Error (%)	Output of the conjugate gradient algorithm(10^4m^3)	Error (%)	Measured value (10^4m^3)

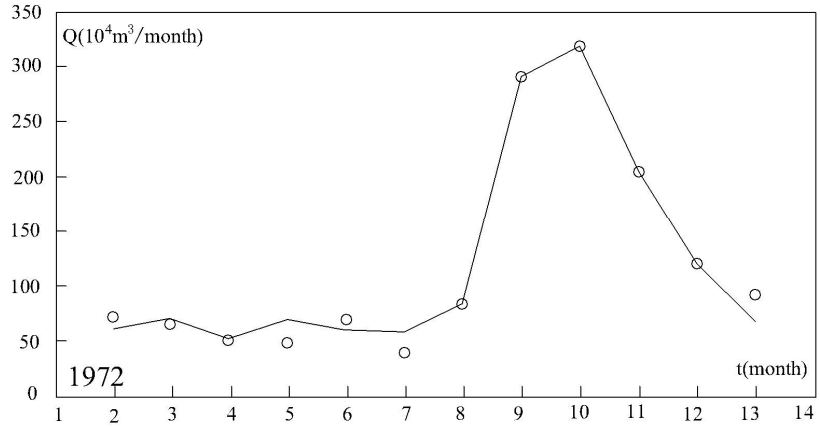

Fig.3 Output Fitting Figure

3. Conclusions

1. Neural network has the advantage of large-scale parallel processing, distributed information storage, continuous-time nonlinear dynamics, global collective action, a high degree of fault tolerance and robustness, redundancy, self-learning and real-time processing, It laid the application foundation for the neural network in the research for groundwater. It will achieve unimaginable process that the traditional methods cannot reach if we introduce neural network into groundwater research areas.

2. The standard B-P method, based on the gradient descent method (LMS), has defects on long training time and slow convergent speed due to its first derivative approaches zero when closes to the local minima. Therefore, this paper presents a new BP learning algorithm - using variable step size, joint learning algorithm of conjugate gradient methods and γ factor items (ULA), the standard BP algorithm overcomes the defects. And theory and practice demonstate the algorithm's effectiveness and superiority.

3. Currently, there still exist many problems with BP neural networks, such as structure of BP network, training and promotion problems. There's no generally accepted theory about groundwater research on the application of BP network number of hidden layer nodes. The defect that B-P network will be a little slow when training, is affected by the marketing capabilities and characteristics of the sample, the network structure, the role of the node function, learning algorithms, data normalization methods and other factors. We need further research about what method will be suitable for the characteristics of groundwater.

Keywords: Football coach; Fuzzy evaluation; Football Coach Selection; Comprehensive scores

Abstract. In this paper, the problem of selecting football coach is analyzed and studied. Concretely, a new index system of evaluating the football coach which includes coaching ability, team scores and personal achievement is designed, and then a comprehensive evaluation model based on fuzzy mathematics is presented to rank all candidates and to select the optimal football coach. Therefore, a novel and effective way is obtained to solve the problem of evaluating the comprehensive level of football coaches under the uncertain information.

Introduction

With the improvement of the modern life quality, more and more people are focus on physical exercise such as long-distance running, volleyball, baseball and football, especially on Football. Football refers to a number of sports that involve, to varying degrees, kicking a ball with the foot to score a goal[1]. The most popular of these sports worldwide is association football, more commonly known as just "football" or "soccer". Unqualified, the word football applies to whichever form of football is the most popular in the regional context in which the word appears, including association football, as well as American football, Australian rules football, Canadian football, Gaelic football, rugby league, rugby union, and other related games[2]. These variations of football are known as football codes. During the twentieth century, several of the various kinds of football grew to become among the most popular team sports in the world[3]. Nowadays, many countries devote to the development of football, and to focus on the national soccer team.

For a professional national soccer team, selecting the right coaching staff is crucial for success in football games in the world. It is important that head coaches trust and get alone with their assistant coaches. In order to choose the best all time football coach for a professional football team, we must find effective evaluation index system and reasonable evaluation method to rank alternative football coach[4-5]. For this research background, we study the problem of selecting football coach this paper. Firstly, we will design a new index system of evaluating the football coach, and then we will present a comprehensive evaluation model based on fuzzy mathematics to rank all candidates and to select the optimal football coach.

The rest of this paper is organized as follows. Section 2 gives the problem description. Section 3 presents a hybrid multi-attribute decision making to select the winners. Section 4 provides concluding remarks.

The Evaluation Index System

The evaluation index system is the key to the selection of the optimal football coach. Referring to the existing literatures and information on the valuation index system of selecting the optimal football coach, we choose coaching ability (u_1), team scores (u_2), and personal achievement (u_3) as three first-grade attributes. Moreover, professional training (u_{11}), seniority (u_{12}) and managing ability (u_{13}) are the corresponding second- grade attributes for the coaching ability, and team's progressing rate (u_{21}), stability (u_{22}) and winning rate (u_{23}) are the corresponding second-grade attributes for the team

scores, and popularity (u_{31}) and personal awards (u_{32}) are two second-grade attributes for personal achievement. All attributes are listed in the following Table 1.

Table1. The evaluation index system of selecting the optimal football coach

The first-grade index	The second-grade index
u_1 Coaching ability	u_{11} Professional Training
	u_{12} Seniority
	u_{13} Managing ability
u_2 Team scores	u_{21} Team's Progressing rate
	u_{22} Stability
	u_{23} Winning rate
u_3 Personal	u_{31} Popularity
achievement	u_{32} Personal awards

The Comprehensive Evaluation Model of Selecting Football Coach

In this section, we will present a fuzzy comprehensive evaluation method to rank and select the optimal football coach. Fuzzy comprehensive evaluation method is a comprehensive evaluation method which is based on fuzzy mathematics, and is a method to transfer qualitative evaluation into quantitative evaluation[8-11]. For the comprehensive evaluation of football coaches, the detailed decision steps are given as follows.

(1) Determine the candidate set.

We suppose there are *m* alternative football coaches participate in the evaluation, and the candidate set is denoted as $X = \{x_1, x_2, \cdots, x_m\}$.

(2) Determine the set of evaluation attributes and the weight set.

From the evaluation attributes given in Table 1, the set of the first-grade index is $U = \{u_1, u_2, u_3\}$, and the sets of the second-grade attributes are $u_1 = \{u_{11}, u_{12}, u_{13}\}$, $u_2 = \{u_{21}, u_{22}, u_{23}\}$ and $u_3 = \{u_{31}, u_{32}\}$. The weight set of the first-grade index is denoted as $W = \{w_1, w_2, w_3\}$, which satisfy the condition $\sum_{i=1}^{3} w_i = 1$. The weight set of the *j*-th second-grade attributes is denoted as $W_j = \{w_{j1}, w_{j2}, w_{j3}\}$, $j = 1,2,3$, where satisfy the condition $\sum_{t=1}^{3} w_{jt} = 1$. Here we set

$W = \{w_1, w_2, w_3\} = \{0.3, 0.5, 0.2\}$,

$W_1 = \{w_{11}, w_{12}, w_{13}\} = \{0.4, 0.3, 0.3\}$,

$W_2 = \{w_{21}, w_{22}, w_{23}\} = \{0.5, 0.25, 0.25\}$,

$W_3 = \{w_{31}, w_{32}\} = \{0.5, 0.5\}$.

(3) Determine the evalution set.

We suppose the grades of the evaluation are worse, bad, common, good, better[12-15]. Then the evulation set is denoted as $V = \{v_1, v_2, \cdots, v_5\}$ ={worse, bad, common, good, better}. For the convenience of calculation, here we set $V = \{v_1, v_2, \cdots, v_5\}$ ={worse, bad, common, good, better}={2, 4, 6, 8, 10}.

(4) Determine the evalution matrix.

For the set of the second-grade attributes $u_1 = \{u_{11}, u_{12}, u_{13}\}$ and the evulation set $V = \{v_1, v_2, \cdots, v_5\}$, we can determine a evalution matrix

$$R_1 = \begin{pmatrix} r_{11} & r_{12} & r_{13} & r_{14} & r_{15} \\ r_{21} & r_{22} & r_{23} & r_{24} & r_{25} \\ r_{31} & r_{32} & r_{33} & r_{34} & r_{35} \end{pmatrix}$$

where $r_{ij} = R(u_{1i}, v_j)$ is the membership (that is, the possibility degree) of u_{1i} on the grade v_j, and $r_{ij} \in [0,1]$, $i = 1,2,3$, $j = 1,2,\cdots,5$.

Similarly, we can obtain the evalution matrix R_2 of the set of the second-grade attributes $u_2 = \{u_{21}, u_{22}, u_{23}\}$ and the evulation set $V = \{v_1, v_2, \cdots, v_5\}$, and the evalution matrix R_3 of the set of the second-grade attributes $u_3 = \{u_{31}, u_{32}\}$ and the evulation set $V = \{v_1, v_2, \cdots, v_5\}$, i.e.,

$$R_2 = \begin{pmatrix} r_{11}^{/} & r_{12}^{/} & r_{13}^{/} & r_{14}^{/} & r_{15}^{/} \\ r_{21}^{/} & r_{22}^{/} & r_{23}^{/} & r_{24}^{/} & r_{25}^{/} \\ r_{31}^{/} & r_{32} & r_{33}^{/} & r_{34}^{/} & r_{35}^{/} \end{pmatrix},$$

$$R_3 = \begin{pmatrix} r_{11}^{//} & r_{12}^{//} & r_{13}^{//} & r_{14}^{//} & r_{15}^{//} \\ r_{21}^{//} & r_{22}^{//} & r_{23}^{//} & r_{24}^{//} & r_{25}^{//} \end{pmatrix}.$$

(5) Make the comprehensive evalution for a single football coach.

For the u_i, the primary evaluation vector is

$$w_i \mathrm{O} R_i = (b_{i1}, b_{i2}, b_{i3}, b_{i4}, b_{i5}) \underline{\underline{\Delta}} B_i, \ i = 1,2,3$$

We set

$$R = \begin{pmatrix} B_1 \\ B_2 \\ B_3 \end{pmatrix} = \begin{pmatrix} b_{11} & b_{12} & b_{13} & b_{14} & b_{15} \\ b_{21} & b_{22} & b_{23} & b_{23} & b_{25} \\ b_{31} & b_{32} & b_{33} & b_{34} & b_{35} \end{pmatrix}.$$

For the $U = \{u_1, u_2, u_3\}$, the secondary evaluation vector is

$$B_k = W \mathrm{O} R = (w_1, w_2, w_3) \mathrm{O} \begin{pmatrix} b_{11} & b_{12} & b_{13} & b_{14} & b_{15} \\ b_{21} & b_{22} & b_{23} & b_{23} & b_{25} \\ b_{31} & b_{32} & b_{33} & b_{34} & b_{35} \end{pmatrix}, \ k = 1,2,\cdots,m$$

$$\underline{\underline{\Delta}} (b_{k1}, b_{k2}, b_{k3}, b_{k4}, b_{k5})$$

where b_{kj} eans the subordinate degree of the alternative football coach k to the grade v_j, $j = 1,2,\cdots,5$.

(6) Rake all football coaches according to the comprehensive scores.

we set Z =(2, 4, 6, 8, 10)^T, and the the the comprehensive score of the alternative football coach k is

$$S_k = B_k \cdot Z = (b_{k1}, b_{k2}, b_{k3}, b_{k4}, b_{k5}) \begin{pmatrix} 2 \\ 4 \\ 6 \\ 8 \\ 10 \end{pmatrix} = 2b_{k1} + 4b_{k2} + 6b_{k3} + 8b_{k4} + 10b_{k5}$$

We can rank all alternative football coaches according to the comprehensive score S_k. The greater the value of S_k is, the better the alternative football coach is. Thus we can select the alternative football coach with the greatest score as the final winner.

Conclusions

In this paper, we design a new index system for evaluating the football coaches, and then a comprehensive evaluation model based on fuzzy mathematics is presented to rank all candidates and to select the optimal football coach. This fuzzy comprehensive evaluation method is a kind of easily-operative, efficient and convenient method to apply in the practice. And this method can be widely used in all kinds of coach selection of the regular ball games.

Calculation of dynamic stress intensity factor by the boundary element - Laplace transform method

Wei Zhang

Shenzhen Polytechnic Guangdong 518008, PR China

1215556531@qq.com

Keywords: Boundary element method, Dynamic stress intensity factor, Laplace transform

Abstract: Using the Laplace transform and freezing time variable, the problem in the time domain into the frequency domain to solve the problem. The establishment of a crack unit model in the frequency domain, and the boundary integral equation and discrete form containing the crack unit has been deduced. While using Durbin algorithm suitable for transient dynamic response of the inverse Laplace transform, the amount of stress intensity factor of a set of transformation parameters corresponding to the frequency domain into a time domain to obtain the dynamic stress intensity factor of time curve, and calculate the stress intensity factor compared to the boundary finite element method has a Laplace transform high precision, easy to save CPU time and data preparation features, we recommend using this method to calculate the dynamic stress intensity factor.

Boundary element - Laplace transform method, basic formula

Set isotropic , homogeneous , linear elastic displacement and stress cracking body R , and flexibility to meet the equations of motion , physical equations and boundary conditions , the entire elastomer displacement at t = 0^+ time , speed :

$$\left.\begin{aligned} \mathrm{u}_j(z,\ y,\ o^+) &= \mathrm{u}_j(o) \\ \dot{\mathrm{u}}_j(z,\ y,\ o^+) &= \dot{\mathrm{u}}_j(o) \end{aligned}\right\} x, y \in R \tag{1}$$

Laplacian function is defined as:

$$\tilde{\mathrm{f}}(\mathrm{x},\ \mathrm{y},\ \mathrm{s}) = \int_0^\infty f(\mathrm{x},\ \mathrm{y},\ t)e^{-st}dt \tag{2}$$

After the Laplace transform elasticity equations of motion after the physical equations and boundary conditions are

$$(c_1^{\,2} - c_2^{\,2})\tilde{u}_{i,\ \mathrm{ij}} + c_2^{\,2}\tilde{u}_{j,\ \mathrm{ij}} + \tilde{F}_j = 0 \tag{3}$$

$$\sigma_{ij} = \rho\left[(c_1^{\,2} - 2c_2^{\,2})\tilde{u}_{m,\ m}\delta_{ij} + c_2^{\,2}(\tilde{u}_{i,\ j} + \tilde{u}_{j,\ i})\right] \tag{4}$$

$$\tilde{\sigma}_{ij}n_j = \tilde{P}_i(x,\ y,\ s); \tilde{u}_i = \tilde{u}_i(x,\ y,\ s) \tag{5}$$

$$\tilde{\mathrm{F}}_\mathrm{j} = \tilde{\mathrm{f}}_\mathrm{j} - \mathrm{s}^2\tilde{\mathrm{u}}_\mathrm{j} + \mathrm{u}_\mathrm{j}(\mathrm{o}) + \dot{\mathrm{u}}_\mathrm{j}(\mathrm{o})\cdot\mathrm{s};$$

$\tilde{\mathrm{f}}\mathrm{j}$ is Physical density of the Laplace transform of elastomer type.C_1, C_2 for the P-wave, S-wave velocity and

$$\mathrm{C}_1 = \sqrt{G/\rho(1-2\cdot\nu)}\ ; \qquad \mathrm{C}_2 = \sqrt{G/\rho}$$

G, ν is the elastic constant of the material, ρ is the mass density.

In the role of an infinite plane concentrated force, to meet the basic solution of equation (3) is automatically Kelvin solution is:

$$\tilde{\mathrm{u}}_{\mathrm{ji}} = \frac{1}{2\pi\rho\mathrm{c}_2^{\,2}}\left(\psi\cdot\delta_{\mathrm{ij}} - \mathrm{x}\mathrm{r}_{,\mathrm{i}}\mathrm{r}_{,\mathrm{j}}\right)$$

$$\mathrm{T}_{\mathrm{ji}} = \frac{1}{2\pi}\left(\left(\frac{\mathrm{d}\psi}{\mathrm{dr}} - \frac{\mathrm{x}}{\mathrm{r}}\right)\left(\delta_{\mathrm{ij}}\frac{\partial\mathrm{r}}{\partial\mathrm{n}} + \mathrm{r}_{,\mathrm{j}}\mathrm{n}_\mathrm{i}\right) - \frac{2}{\mathrm{r}}\bar{\mathrm{x}}\left(\mathrm{n}_\mathrm{j}\mathrm{r}_{,\mathrm{i}} - 2\mathrm{r}_{,\mathrm{i}}\mathrm{r}_{,\mathrm{j}}\frac{\partial\mathrm{r}}{\partial\mathrm{n}}\right) -\right.$$

$$2\frac{dx}{dr}r_{,i}r_{,j}\frac{\partial r}{\partial n}+\left(\frac{c_1^{\,2}}{c_2^{\,2}}-2\right)\cdot\left(\frac{d\psi}{dr}-\frac{dx}{dr}-\frac{x}{r}\right)\cdot r_{,i}n_j\Bigg) \tag{6}$$

Where: $\psi=K_0\left(\frac{s\cdot r}{c_2}\right)+\frac{c_2}{s\cdot r}\left(K_1\left(\frac{s\cdot r}{c_2}\right)-\frac{c_2}{c_1}K_1\left(\frac{s\cdot r}{c_1}\right)\right)$

$$X=K_2\left(\frac{s\cdot r}{c_2}\right)-\frac{c_2^{\,2}}{c_1^{\,2}}K_2\left(\frac{s\cdot r}{c_1}\right)$$

$K_0\left(\frac{s\cdot r}{c_i}\right),K_1\left(\frac{s\cdot r}{c_i}\right),K_2\left(\frac{s\cdot r}{c_i}\right)$ are denatured zero class, first class, second class Bessel functions.Betty swaps by the theorem:

$$c_i\tilde{u}_j(P,S)=\int_L\left(\tilde{u}_{ji}(P,Q)\tilde{t}_i(Q)-\tilde{T}_{ji}(P,Q)\tilde{u}_i(Q)\right)\cdot dL(Q) \tag{7}$$

Ci=1 when P located in the bady R and Q located on the border L; Ci=1/2 when P ,Q located on the border L;Ci=0 when P located in the non-bady R;When P, Q while located on the border L, using equation (7) obtained stress or displacement boundary frequency domain. Then the stress and displacement obtained by the inverse Laplace transform domain using the same procedure, obtain the stress and displacement fields R interior point.

Cracking unit and numerical techniques

Calculation of stress intensity factor distributions in the form of units on the accuracy of the crack tip stress and displacement assumptions related. Due to the constant unit can not simulate the crack tip singularity, so the use of such a single unit can not get accurate results. Linear or quadratic even though higher-order unit can improve the accuracy of the application subject to significantly increase the time count. Due to the dynamic stress intensity factor required to calculate a set of transformation parameters corresponding to S_i in the frequency domain $K(S_i)$ only after obtaining, equivalent to several times the corresponding static calculation problem. Computing time so the problem is more prominent than the corresponding static problem, for both the use of an improved calculation accuracy and reducing CPU time method for the calculation of dynamic stress intensity factor, it is very necessary.

Frequency domain of the crack tip stress and displacement distribution has the following form: (I type)

$$\left.\begin{aligned}
\tilde{\sigma}_x(r,\ \theta,\ s)&=\frac{\tilde{K}_1(s)}{(2\pi\cdot r)^{\frac{1}{2}}}\cos\frac{\theta}{2}\left(1-\sin\frac{\theta}{2}\sin\frac{3\theta}{2}\right)\\
\tilde{\sigma}_y(r,\ \theta,\ s)&=\frac{\tilde{K}_1(s)}{(2\pi\cdot r)^{\frac{1}{2}}}\cos\frac{\theta}{2}\left(1-\sin\frac{\theta}{2}\sin\frac{3\theta}{2}\right)\\
\tilde{\tau}_{xy}(r,\ \theta,\ s)&=\frac{\tilde{K}_1(s)}{(2\pi\cdot r)^{\frac{1}{2}}}\sin\frac{\theta}{2}\cdot\cos\frac{\theta}{2}\cdot\cos\frac{3\theta}{2}\\
\tilde{u}_x(r,\ \theta,\ s)&=\frac{\tilde{K}_1(s)}{G(1+\nu_1)}\cdot\sqrt{\frac{r}{2\pi}}\cos\frac{\theta}{2}\left(\left(1-\nu_1\right)+(1+\nu_1)\cdot\sin^2\frac{\theta}{2}\right)\\
\tilde{u}_y(r,\ \theta,\ s)&=\frac{\tilde{K}_1(s)}{G(1+\nu_1)}\cdot\sqrt{\frac{r}{2\pi}}\sin\frac{\theta}{2}\left(2-(1+\nu_1)\cdot\cos^2\frac{\theta}{2}\right)
\end{aligned}\right\} \tag{8}$$

For plane stress $\nu_1=\nu$; plane strain $\nu_1=\nu/(1-\nu)$.As can be seen from the above equation, the crack tip stress in the frequency domain with strange sex. Therefore, assuming that the distribution of the boundary element stress and displacement at the crack tip is:

$$\left.\begin{aligned}\tilde{t}(r,\ s)&=\sum_{i=1}^{k}\alpha_i r^{(i-3/2)}\\ \tilde{u}(r,\ s)&=\sum_{i=1}^{k}\beta_i r^{(i-1/2)}\end{aligned}\right\} \tag{9}$$

Write forming function form:

$$\left.\begin{aligned}\tilde{t}(r,\ s)&=\sum_{i=1}^{k}N_i(r)\cdot\tilde{t}_i(r,\ s)\\ \tilde{u}(r,\ s)&=\sum_{i=1}^{k}M_i(r)\cdot\tilde{u}_i(r,\ s)\end{aligned}\right. \tag{10}$$

$N_i(r)$, $M_i(r)$ is the stress and displacement shape function.

In the non-displacement of the crack tip stress distribution that is assumed to be constant

$$\left.\begin{aligned}\tilde{t}(x,\ y,\ s)&=\tilde{t}_i\\ \tilde{u}(x,\ y,\ s)&=\tilde{u}_i\end{aligned}\right\} \tag{11}$$

The latter formula (10) to (11) into (7), and discrete are:

$$C_iU_i(Q)=\sum_{i=kw\cdot 2+1}^{2\cdot W}\cdot\sum_{i=1}^{k}\left(\tilde{t}_i(Q)\cdot\int_{\Delta L}U_{ji}(P,Q)\cdot N_i(P,Q)\,dL-\tilde{U}_i(Q)\cdot\int_{\Delta L}\tilde{T}_{ji}(P,Q)\cdot\right.$$

$$\left.M_i(P,Q)\,dL+\sum_{i=kw\cdot 2+1}^{N}\left(\tilde{t}_i(Q)\cdot\int_{\Delta L}\cdot\tilde{V}_{ji}(P,Q)\cdot dL-\tilde{U}_i(Q)\int_{\Delta L}\cdot\tilde{T}_{ji}(P,Q)\cdot dL\right)\right. \tag{12}$$

Where u crack crack tip several bodies. When $i \neq j$, the formula uses the integral is a regular point or four-point Gaussian integral formula can be obtained. When i = j where the integral is odd, and the plot function is deformed Bessel functions. Due to boundary elements, thus integrating with analytic expressions. Due to space limitations not listed

Form of the formula (12) into the matrix include:

$$[\tilde{G}]\cdot[\tilde{U}]=[\tilde{H}]\cdot[\tilde{t}] \tag{13}$$

For displacement and stress array, displacement and stress coefficient matrix, for any boundary conditions by the formula (13) obtained the frequency domain stress and displacement, and the stress intensity factor domain, by the crack tip attached:

$$K_i(S_i)=\lim_{r\to 0}\tilde{t}(r,s)\cdot\sqrt{2\pi\cdot r}=\sqrt{2\pi}\alpha_1 \tag{14}$$

Obtain a set of transformation parameters corresponding to Si after the stress intensity factor by numerical inversion of Laplace transform too, can find the time factor domain. Ⅱ, Ⅲ crack calculated intensity factors associated with type I different.

Numerical inverse Laplace transform method

Durbin method is based on sine, cosine transform, on ways to improve Dubner and Abatr come. Required in a complex field operations. But its transformation results in T's early, mid valid, suitable for dramatic changes over time transform function.

$$f(t_j)=2(e^{\beta j\Delta t}/T)\left(\mathrm{Re}\left(-\frac{1}{2}f(\beta)+\sum_{n=0}^{N-1}(A(n)+i\cdot B(n))\cdot w^{jn}\right)\right)$$

$$A(n)=\sum_{i=0}^{L}\mathrm{Re}\left(\tilde{f}(\beta+i(n+iN)\cdot 2\pi/T)\right)$$

$$B(n)=\sum_{i=0}^{L}\mathrm{Im}(f(\beta+i(n+iN)\cdot 2\pi/T))$$

$$w=e^{2\pi i/N}$$

$n = 0,1,\cdots,\ N,\ i = 0,1,2,\cdots L$

$t_j = j \cdot T/N;\ j = 0,1,\cdots N-1$

Examples

Figure 1 , long plate with a central crack , the elastic constants were G = 76.92 MPa , v = 0.3, ρ = 5000kg/m^3, P , S -wave velocities were C_1 = 6206m / s; C_2= 3922m / s , a=5mm,t = 0 moment , both ends of the plate to withstand sudden tensile load . Take 1 /4 as part of the calculation model, and its boundary is divided into 39 units. Disposed on each side of the crack tip singular means of a three-node , the length of the adjacent cell constant of 1.5 . Inverse Laplace transform using Durbin algorithm , taking N = 20, L = 1, T = 2 × 10^{-3}-s , βT = 5, in the range of 0 ~ 1.0 × 10^{-3}seconds , the Laplace error caused by the inverse transform of less than 1 % of the time curve of Figure .2 Example of stress intensity factor , the largest results of $K(t)/\sqrt{a}\cdot\sigma$ is 2.7101 , the results 2.6812 of finite element method is slightly larger , the maximum time that appears in 6 ~ 7 × 10^{-3} seconds.

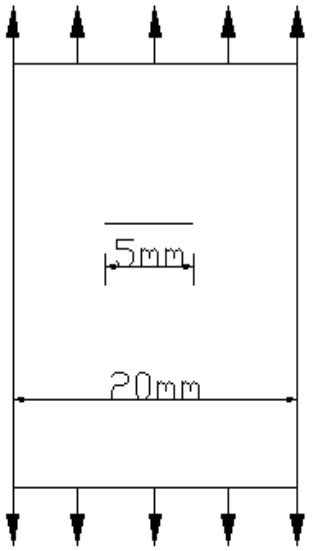

Figure 1

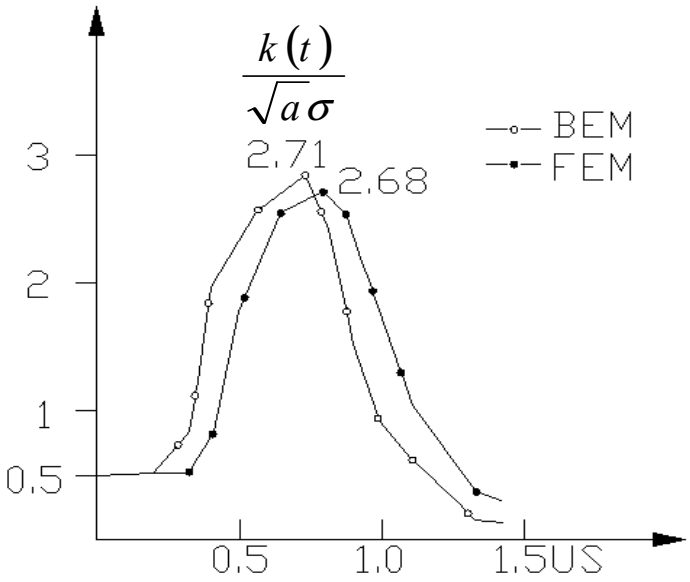

Figure .2

Conclusion

Comparing the finite element method of calculated stress intensity factor , The boundary element - Laplace transform method with high accuracy, easy to save CPU time and data preparation features, we recommend using this method to calculate the dynamic stress intensity factor.

Keywords: quasilinear elliptic equation; thin film; point rupture; radial solution; singular.

Abstract. We consider the quasilinear elliptic equation $\mathrm{div}(|\nabla u|^{p-2}\nabla u) = f(u)$ in a finite ball in R^N, where $\lim_{u\to 0^+} f(u) = \infty$. Motivated by the thin film equations, a solution u is said to be a point rupture solution if for some $p \in \Omega$, $u(p) = 0$ and $u(x) > 0$ for any $x \in \Omega \setminus \{p\}$. Our main result is a sufficient condition on f for the existence of radial point rupture solutions.

1. Introduction

In this paper we study the existence of radial point rupture solutions of the following problems

$$\mathrm{div}(|\nabla u|^{p-2}\nabla u) = f(u) \ \text{ in } \Omega \tag{1.1}$$

with Neumann boundary condition

$$\frac{\partial u}{\partial n} = 0 \ \text{ on } \partial\Omega \tag{1.2}$$

where $N \geq 2, p \geq 2, \Omega = \{x \in \mathbf{R}^N : |x| < 1\}$ is a ball. The nonlinear function $f \in C^1(0,\infty)$ satisfies that following condition:

$$\lim_{u\to 0^+} f(u) = \infty.$$

By a point rupture solution u of (1.1) in Ω, we mean that for some $p \in \Omega$, $u(p) = 0$ and $u(x) > 0$ for any $x \in \Omega \setminus \{p\}$.

This problem appears in the study of non-Newtonian fluids ([1,2]) and non-Newtonian filtration ([3]). The quantity p is a characteristic of the medium. Media with $p > 2$ are called dilatant fluids and those with $p < 2$ are called pseudoplastics. If $p = 2$, they are Newtonian fluid. In particular it can be the equation equilibrium states in flows of thin films of power-law fluids.

Equations of type

$$u_t = -\mathrm{div}(m(u)|\nabla\triangle u|^{p-2}\nabla\triangle u) - \mathrm{div}(g(u)\nabla u)$$

where u denotes the height from the surface of the oil to the surface of the solid. It was J.R. King [4] who first derived the equation. For the two dimensional case, which has a particular physical derivation as mentioned in [5], modeling the spreading of an oil film over an solid surface. The zero set $\sum = \{u = 0\}$ is the liquid/solid interface and is sometimes called set of ruptures. The coefficient $m(u)$ reflects surface tension effects-a typical choice is $m(u) = u^3$.

In particular, let us assume that $m(u) = u^3, g(u) = -u^l$ with $l < p - 1$, then $l - p < -1$. Then we get the equation

$$\mathrm{div}(|\nabla u|^{p-2}\nabla u) = u^{-l}, \quad l > p - 1. \tag{1.3}$$

We easily see that the solutions of (1.3) can explain the behaviors of steady-states for (1.3) in some special cases. A different type of equation from (1.3)

$$-\mathrm{div}(|\nabla u|^{p-2}\nabla u) = q(x)u^{-l}, \ \ x \in \Omega, \ \ u|_{\partial\Omega} = 0$$

has also been studied in [6] and the references therein.

Now let $\Omega \in R^N$ be the bottom of a cylindrical container occupied by the thin film fluid, we assume that there is no flux across the boundary, which yields the boundary condition $\frac{\partial p}{\partial \nu} = 0 \ \text{ on } \partial\Omega$. We also ignore the wetting or non-wetting effect, and assume that the fluid surface is perpendicular to the boundary of the container, i.e., $\frac{\partial h}{\partial \nu} = 0 \ \text{ on } \partial\Omega$.

We can find the related results for $p = 2$ in [7-9]. The main differences between $p = 2$ and $p \neq 2$ are known in [10-12]. When $p = 2$, it is well known that all the positive solutions in $C^2(B_R)$ of the problem

$$\triangle u + f(u) = 0 \text{ in } B_R,$$
$$u(x) = 0 \text{ on } \partial B_R,$$

and radially symmetric solutions for very general (see [14]). Unfortunately, this result does not apply to the case $p \neq 2$. Kichenassary and Smoller showed that there exist many positive nonradial solutions of the above problem for some f (see [15]). The major stumbling block in the case of $p \neq 2$ is that certain nice features inherent to the case $p = 2$ seem to be lost or at least difficult to verify.

We conjecture that the ruptures are discrete for finite energy solutions, and we expect that the radial point rupture solutions will serve as the blow up profile of the solution near any point rupture. The main purpose of this paper is on the existence of radial point rupture solution. And we are only interested in the local solutions in a neighborhood of the point rupture, extended to results in [7-9, 11-13].

Now we state our main result.

Theorem 1.1. Let $\sigma^* > 0$ and f be a continuous, monotone decreasing positive function on $(0, \sigma^*]$ such that

$$\lim_{v \to 0+} f(v) = \infty.$$

Let

$$G(v) = \int_0^v \frac{|s'|^{p-2}}{f(s)} ds. \qquad (1.4)$$

Then there exists $r^* > 0$ and a radial point rupture solution u_0 to (1.1) in $B_{r^*}(0)$ such that $u_0 = u_0(r)$ is continuous on $[0, r^*]$, $u_0(0) = 0, u_0(r) > 0$ for any $r \in (0, r^*]$, and u is a weak solution to (1.1) in $B_{r^*}(0)$. Moreover, u_0 is monotone increasing and

$$G^{-1}(\tfrac{1}{2N} r^2) \leq u_0(r) \leq \int_0^r (2s^{1-N} G^{-1}(\tfrac{s^2}{2N}))^{\frac{1}{p-1}} ds$$

for any $r \in (0, r^*]$.

Remark 1.2. The assumption that f is monotone decreasing can be replaced by the assumption that f is a product of a monotone deceasing function and a bounded positive function.

2. Proof of Theorem 1.1

To prove Theorem 1.1, we consider radially symmetric solutions of the quasilinear elliptic Eq. (1.1), that is, suppose that $u = u(r)$ with $r = |x| < 1$. For any $\sigma \in (0, \sigma^*)$, we use u_σ to denote the unique solution to the initial value problem

$$(\Phi_p(u'))' + \frac{(N-1)}{r} \Phi_p(u') - f(u(r)) = 0, r > 0, \qquad (2.1)$$
$$u(0) = \sigma, \quad u'(0) = 0, \qquad (2.2)$$

where $\Phi_p(s) = |s|^{p-2} s$.

Definition 2.1. $u \in W_0^{1,p}$ is a positive weak solution to problem (1.1) if $u > 0$, a.e. on Ω and satisfies

$$\int_\Omega |\nabla u|^{p-2} \nabla u \nabla \varphi dx = \int_\Omega f(u) \varphi dx, \text{ for all } \varphi \in W_0^{1,p}(\Omega).$$

Lemma 2.2. There exists $r_\sigma > 0$ such that u_σ is defined on $[0, r_\sigma]$ with $u_\sigma(r_\sigma) = \sigma^*$. Moreover, $u'_\sigma(r) > 0$ on $(0, r_\sigma]$ and

$$G^{-1}(\tfrac{1}{2N} r^2) \leq u_\sigma(r) \leq \sigma + \int_0^r (2s^{1-N} G^{-1}(\tfrac{s^2}{2N}))^{\frac{1}{p-1}} ds \text{ on } [0, r_\sigma]. \qquad (2.3)$$

Proof. For simplicity, we suppress the σ subscript in this proof. We write (2.1) in the form of $[r^{N-1} \Phi_p(u'(r))]' = r^{N-1} f(u(r)) \geq 0$, so we have $r^{N-1} \Phi_p(u'(r)) = \int_0^r s^{N-1} f(u(s)) ds \geq 0$. In particular, u is monotone increasing and u can be extended whenever $f(u)$ is defined and bounded. Hence, there exists $r_\sigma > 0$ such that u_σ is defined on $[0, r_\sigma]$ with $u_\sigma(r_\sigma) = \sigma^*$.

Since u is monotone increasing and f is monotone decreasing, we have

$$r^{N-1} \Phi_p(u'(r)) = \int_0^r s^{N-1} f(u(s)) ds \geq f(u(r)) \int_0^r s^{N-1} ds = \frac{r^N}{N} f(u(r)),$$

hence, $\frac{\Phi_p(u'(r))}{f(u(r))} \geq \frac{r}{N}$.

Integrating again, we have

$$G(u(r)) \geq G(\sigma) + \frac{r^2}{2N} \geq \frac{r^2}{2N}.$$

Since G is strictly monotone increasing, we have $u(r) \geq G^{-1}(\frac{r^2}{2N})$.

On the other hand,

$$r^{N-1}\Phi_p(u'(r)) = \int_0^r s^{N-1} f(u(s))ds \leq \int_0^r s^{N-1} f(G^{-1}(\frac{s^2}{2N}))ds.$$

Let $v = G^{-1}(\frac{s^2}{2N})$, we have $G(v) = \frac{s^2}{2N}$ and $\frac{|v'|^{p-2}}{f(v)}dv = \frac{s}{N}ds$.

Hence

$$\int_0^r f(G^{-1}(\frac{s^2}{2N}))sds = \int_0^{G^{-1}(\frac{s^2}{2N})} 2dv = 2G^{-1}(\frac{s^2}{2N}).$$

Since $0 < r < 1$, $N \geq 2$, we have

$$\int_0^r s^{N-1} f(G^{-1}(\frac{s^2}{2N}))ds \leq \int_0^r f(G^{-1}(\frac{s^2}{2N}))sds.$$

Thus

$$\Phi_p(u'(r)) \leq 2G^{-1}(\frac{s^2}{2N}).$$

Hence

$$u'(r) \leq (2r^{1-N}G^{-1}(\frac{r^2}{2N}))^{\frac{1}{p-1}}$$

which yields

$$u(r) \leq \sigma + \int_0^r (2s^{1-N}G^{-1}(\frac{s^2}{2N}))^{\frac{1}{p-1}}ds.$$

Corollary 2.3. There exists $r^* > 0$ such that for any $\sigma \in (0, \frac{\sigma^*}{2}]$, $r_\sigma \geq H^{-1}(\frac{\sigma^*}{2})$, where

$$H(u) = \int_0^u (2s^{1-N}G^{-1}(\frac{s^2}{2N}))^{\frac{1}{p-1}}ds.$$

Proof. For any $\sigma \in (0, \frac{\sigma^*}{2}]$,

$$\sigma^* = u_\sigma(r_\sigma) \leq \sigma + \int_0^{r_\sigma} (2s^{1-N}G^{-1}(\frac{s^2}{2N}))^{\frac{1}{p-1}}ds \leq \frac{\sigma^*}{2} + \int_0^{r_\sigma} (2s^{1-N}G^{-1}(\frac{s^2}{2N}))^{\frac{1}{p-1}}ds.$$

Hence

$$\int_0^{r_\sigma} (2s^{1-N}G^{-1}(\frac{s^2}{2N}))^{\frac{1}{p-1}}ds \geq \frac{\sigma^*}{2}.$$

Let

$$H(u) = \int_0^u (2s^{1-N}G^{-1}(\frac{s^2}{2N}))^{\frac{1}{p-1}}ds,$$

So $H(r_\sigma) \geq \frac{\sigma^*}{2}$ implies $r_\sigma \geq H^{-1}(\frac{\sigma^*}{2})$. The point rupture solution can be constructed as the limit of u_σ as $\sigma \to 0$.

Proposition 2.4. There exists a sequence $\{\sigma_k\}_{k=1}^\infty \subset (0, \frac{\sigma^*}{2}]$ satisfying $\lim_{k\to\infty} \sigma_k = 0$, such that $u_{\sigma_k} \to u_0$ uniformly in $\overline{B_{r^*}(0)}$ as $k \to \infty$, for some function $u_0 \in C^0(\overline{B_{r^*}(0)}) \cap C^2(\overline{B_{r^*}(0)} \setminus \{0\})$. Moreover, u_0 is a classical solution to (1.1) in $B_{r^*}(0) \setminus \{0\}$ and

$$G^{-1}(\tfrac{1}{2N}r^2) \leq u_0(r) \leq \int_0^r (2s^{1-N}G^{-1}(\tfrac{s^2}{2N}))^{\frac{1}{p-1}}ds \ \text{ on } \ [0, r^*].$$

Proof. For any $\varepsilon > 0$, $u_\sigma, \sigma \in (0, \frac{\sigma^*}{2}]$ is a family of uniformly bounded classical solutions to

$$\mathrm{div}(|\nabla u|^{p-2}\nabla u) = f(u) \ \text{ in } \overline{B_{r^*}(0)} \setminus B_\varepsilon(0),$$

hence by a diagonal argument, there exists a sequence $\{\sigma_k\}_{k=1}^\infty \subset (0, \frac{\sigma^*}{2}]$ satisfying $\lim_{k\to\infty} \sigma_k = 0$, such that $u_{\sigma_k} \to u_0$ locally uniformly in $\overline{B_{r^*}(0)}$ as $k \to \infty$.

Now (2.3) implies

$$G^{-1}(\tfrac{1}{2N}r^2) \leq u_0(r) \leq \int_0^r (2s^{1-N}G^{-1}(\tfrac{s^2}{2N}))^{\frac{1}{p-1}}ds \ \text{ on } \ [0, r^*].$$

Since

$$\lim_{r\to 0} \int_0^r (2s^{1-N}G^{-1}(\tfrac{s^2}{2N}))^{\frac{1}{p-1}}ds = 0,$$

it is not difficulty to see, from the bounds of u_σ and u_0, that $u_{\sigma_k} \to u_0$ uniformly in $\overline{B_{r^*}(0)}$ as $k \to \infty$.

Proposition 2.5. $f(u_0) \in L^1 B_{r^*}(0)$ and u_0 is a weak solution to (1.1) in $B_{r^*}(0)$.

We omit the proofs here. From proposition 2.4 and 2.5, we can get Theorem 1.1.

Keywords: Wireless sensor network; routing protocol; ant colony algorithm

Abstract. Wireless sensor networks (WSN) have become a hot research topic in the field of computer science. Since WSNs are characterized by limited node energy, dynamic topological structure and data fusion, the design of WSN routing protocols is faced with new problems and challenges. In recent years, many new routing algorithms for wireless sensor networks have appeared, but they all have some shortcomings. This paper studies and analyzes these routing protocols, and in view of their shortcomings, proposes a WSN hierarchical routing protocol based on ant colony algorithm. And a simulation test is conducted on this improved routing protocol, and the simulation result proves that this algorithm basically achieves the design objectives of WSN routing algorithms.

Introduction

Routing protocols play an important role in WSN communications, and currently focus on the network layer and the link layer. Routing algorithms have become a core technology of wireless sensor networks. Based on the WSN features, a WSN routing protocol should take energy efficiency as the primary goal. Ant colony algorithm is a heuristic, intelligent, evolutionary algorithm that simulates the behavior of ants searching for food, and suitable for solving complex combinatorial optimization problems. The application to WSN routing problems shows that ant colony optimization algorithm has excellent global optimization performance.

Wireless sensor networks and routing protocols

1. WSN system architecture and features

WSN is composed of sensor nodes, Sink nodes, wireless communication network and end users. The nodes are randomly deployed and organized by themselves into a network. Data information is sensed, processed by sensor nodes and transmitted through the hop transmission mode to Sink nodes, and then through the network to remote end users. WSNs have large scale, multiple routes and limited capabilities of senor node and, are self-organizing, dynamic and data centric.

A node comprises an energy module, a perception module, an information processing module, a storage module, a data transmission module and a software module. Since nodes have limited energy, the nodes running out of power cannot work. Therefore, low power consumption electronic devices and effective energy control methods should be used as many as possible to extend the lifetime of a network. The design of routing protocols is also centered on energy efficiency.

2.WSN routing algorithms and features

Routing algorithms play a significant role in WSN routing protocols, determine the data transmission route and influence the performance of the routing protocols. WSN routing algorithms should be concise, energy-saving, extensible, and have strong robustness and fast convergence. In terms of network topology, routing protocols can be divided into flat routing protocols and hierarchical routing protocols. The hierarchical routing has low and uniform energy consumption, is capable of reducing communication and storage overhead and the impact incurred by the change in the network topology, and has convenient and effective communication among and management of

cluster nodes. These advantages make hierarchical algorithms a hot research topic in the current studies on WSN routing protocols.

3. Representative WSN hierarchical routing protocols

(1)LEACH protocol is the first hierarchical routing protocol. It adopts periodic election of cluster head to balance the energy consumption of nodes and extend the life cycle of the network. With the hierarchy, data transmission is controlled within the clusters, and through data aggregation and fusion, the cluster heads which are elected in a distributed way can reduce the energy consumed by node data transmission. The intra-cluster nodes can close the transceivers to prevent unnecessary interception, hence increasing by 15% of the life cycle of the network. However, the more the total nodes in application, the more the cluster heads and the farther away the cluster head is from the base station and the faster the energy consumption of the cluster head is, which seriously influences the coverage and lifetime of the network. Therefore, LEACH algorithm is not applicable to the sensor networks with large coverage area.

(2)PEGASIS protocol is developed on the basis of LEACH protocol. It reduces the transmission times and data volume to the base station or the sink nodes, that is, it has more reasonable deployment of nodes and better data fusion. All nodes send and test broadcast signal and then detect the responses to determine the nearest nodes and know about their positional relations, which ensures the optimal links and low power consumption of the entire network. However, this protocol has low communication efficiency and longer time delay, especially in the case of a large number of nodes. Furthermore, this algorithm only considers the distance between the neighbor nodes, and ignores such factors as the node energy and the overall energy consumption of the network.

(3)GAF protocol is one in which the network area is divided into a number of virtual cells on the basis of the location information of nodes. Each cell is a cluster, in which a cluster head is elected regularly. The node serving as the cluster head is in active state, while the rest nodes go to sleep. The sleeping nodes have their own timers, and once the sleeping time is up, they convert from the sleep state into the active state and vie for cluster head. GAF algorithm features the division of clusters based on the virtual cells, but it considers that the nodes are in the same physical horizontal plane, and does not take into account that the adjacent distance between the nodes of the actual network does not means the direct communication between the nodes.

It can thus be seen that a hierarchical algorithm is composed of the generation of cluster heads, the formation of clusters and the routes of clusters. The generation of cluster heads serves as the basis of the formation of clusters, and the routes of clusters, i.e., the data transmission of clusters depends on the structure of the clusters. These closely-related three parts are the key to the design of WSN hierarchical routing protocols.

Ant colony algorithm is suitable for a dynamic environment and good at local work; it can optimize various parameters and support multiple routes; the simple individual behavior of the ant colony agrees with the limited capability of sensor nodes. These features account for the favorable applicability of ant colony algorithm to WSNs.

Design of IACH hierarchical routing protocol based on ant colony algorithm

1. Core thought

Based on PEGASIS and LEACH protocols and with reference to their advantages, this paper puts forward a hierarchical routing protocol based on ant colony algorithm, whose core thought consists of the following three points:

(1) To replace the greedy algorithm in PEGASIS algorithm by the improved ant colony algorithm to construct chains.

(2) To avoid long chains and use LEACH algorithm for clustering and form chains within the clusters.

(3) To use the improved ant colony algorithm to form a chain again among the cluster heads which are obtained by LEACH algorithm; data are sent by the chain head to the base station.

2. Concrete steps

(1) The cluster head nodes are elected according to LEACHalgorithm and, other nodes join in the clusters;

(2) The intra-cluster nodes are constructed into a chain according to the improved ant colony algorithm and, the chain begins with the node with the highest remaining energy;

(3) Intra-cluster data are transmitted from the node farthest away from the cluster head and to the cluster head through infusion and forwarding;

(4) The cluster head extends the node chain, fuses again the data it has received and collected, and then sends the data after being fused by the chain head node to the base station;

(5) After a round of communication is over, the above steps are repeated to achieve energy consumption balance for the nodes of the network.

3. Communication model

(1) Assumed conditions

Assuming that a wireless sensor network comprises N sensor nodes, which are deployed randomly in a vast region to periodically collect data, the sensor nodes and the underlying network model are as follows:

① The base station is located beyond the monitored region. Take an apex of the rectangular region as the origin of coordinates, and the two sides this apex is on as the coordinate axes, establish a coordinate system, and the rectangular region is in the first quadrant;

② The base station has strong computing and storage capabilities and its energy can be supplemented;

③ All sensor nodes are static and have the same primary energy and communication capacity; they die after their energy runs out;

④ The communication radius of the nodes can be changed, that is, their wireless transmit power can be adjusted.

(2) Communication model

The wireless communication model is given a threshold value. When the distance between the sending node and the receiving node is less than d_0, the energy loss of the sending node in sending the data is proportional to the square of the distance, otherwise it is proportional to the biquadrate of the distance. These two different energy loss models are called the free space model and the multiple attenuation model respectively. Therefore, based on the distance between the sending node and the receiving node, different energy consumption models can be used to calculate the energy needed for sending the data. For the transmission of L bits of data to the location with distance d, the energy consumed by a node is composed of the transmission circuit loss and the power amplification loss,

$$\begin{aligned} E_{Tx}(L,d) &= E_{Tx-elec}(L) + E_{Tx-amp}(L,d) \\ &= \begin{cases} lE_{elec} + L\varepsilon_{fs}d^2 & d < d_0 \\ lE_{elec} + L\varepsilon_{mp}d^4 & d \gg d_0 \end{cases} \end{aligned} \quad (1)$$

$E_{Tx-elec}$ is the energy consumed by starting the wireless transmission circuit, E_{Tx-amp} is the energy consumption of the amplifier, and E_{elec} is the energy loss of the transmission circuit. If the transmission distance is less than the threshold value d_0, the power amplification loss adopts the free space model; if the transmission distance is equal or more than the threshold value d_0, the multiple attenuation model is adopted. ε_{fs}, ε_{mp} are the energy consumed by power amplification in these two models.

The energy consumed by the node receiving L bits of data:

$$E_{Rx}(L) = lE_{elec} \quad (2)$$

Data fusion also consumes some energy. E_{DA} refers to the energy consumed by fusing the data per bit. Assuming that the data collected by the adjacent nodes have high redundancy, and the cluster head can fuse the data of its members into a data package with fixed length and then send it to the base station.

The threshold value d_0 is determined by the following equation:

$$\boldsymbol{d_0 = \sqrt{\varepsilon_{fs}/\varepsilon_{mp}}} \quad (3)$$

Simulation analysis based on IACH algorithm

NS2 is the acronym of network simulator, and is essentially a discrete-time simulation system (DES). Its major function is to simulate the information transmission between the nodes of the actual network, and to guide the development of network protocols with the useful conclusions drawn based on the analysis of the simulation results. LEACH, PEGASIS and IACH protocols are simulated and their performances are compared in NS2. The nodes in the simulation are distributed in the 200m× 200m region, and the coordinates of the base station is (100,400).

A sensor node dies when its energy is zero. The number of the surviving nodes can reflect the life circle of the network. First Node Died, Half Node Died, and Last Node Died are defined. The time table of the three protocols in simulation is shown in Table 1.

Table1Network lifetime table

Protocol	First Node Died	Half Node Died	Last Node Died
LEACH	87	92	109
PEGASIS	169	203	234
LACH	209	251	291

It can be seen that the first node death time, the half node death time, and the last node death time of IACH protocol, are much higher than those of LEACH and PEGASIS protocols, and thus IACH protocol is highly effective.

Conclusion

This paper analyzes the features of wireless sensor networks, elaborates the features and classification of WSN-based routing protocols, and studies the advantages and disadvantages of several representative routing protocols. Then it introduces ant colony algorithm into the design of WSN hierarchical routing protocols, puts forward some improvement strategies, and builds a transmission model to conduct simulation and comparative analysis. The simulation and analysis results prove the effectiveness of this protocol in extending the network life cycle and reducing energy consumption.

Abstract. This paper proposes an analysis measure for Big Data by optimizing traditional data mining, base on Weka data analyzing platform，K-means algorithm is employed through the interface programs in Weka system, so that optimized data mining techniques can be applied in cloud storage, cloud computing of Big Data by clustering analysis base on Big Data pre-processing and real-time monitoring of memory.

The bottle-neck in analyzing of Big Data

Large quantities of data are stored in the data of companies and government agencies, but the value of the data is not brought into full play. The lack of effective data integration and data analysis, data mining techniques and methods are the main technical obstacles, but the underlying reasons are the lack of recognition of the potential value of data and the lack of effective methods to extract the value of data.

(1) Big Data figures

Big data is characterized by "3V", i.e., variety, volume and velocity. The data mining methods have bottlenecks to enhance the abilities of analyzing, users must improve the performance of servers, including storage, memory and CPU, which causes the continuous increase in machine cost and power consumption. Currently, the majority of data analysis and mining software are not capable of complex analysis and modeling of Big Data which are no less than terabytes (TB), because such big data exceed the management ability of traditional databases.

With the deeper understanding of the value of big data, another typical feature—value dimension is added, which is used to describe the value of big data. In practical applications, the large-volume data are not necessarily of great value. For example, important analysis and mining cannot be carried out on lots of data before they are effectively integrated, so these data do not have great value. However, data integration itself is a big challenge for big data.

(2) Big Date challenges on traditional date mining

The objects of big data analytics have more and more attributes. Although there are more and more information in the expressed objects, thousands of attributes also result in huge dimensions. Furthermore, the high-dimension data bring about other problems, such as complex data type, noise and default value and unbalanced distribution. Traditional total space method is not suitable for the analysis of high-dimension data, because this kind of data has great sparsity and, the expression of object cluster and class is embodied in some attribute subsets. The effective method is the subspace method. In addition, due to the complexity of data, it is hard for single data mining models, such as the decision tree model, to meet the accuracy requirements of applications. Therefore, the ensemble method of multiple models must be adopted to build a cluster or classification integrating model so as to make the final decision based on the comprehensive results of multiple single models. In analysis, if the rows of the object attribute matrix are more than ten million or a hundred million, the data volume of the whole matrix will reach hundreds of GB or TB. Such huge quantities of input data exceed far beyond the memory of most servers, let alone to model and mine the data on a single server with complex iteration or recursion mining algorithms. Therefore, the existing data mining software and most traditional classification and clustering algorithms cannot handle the data of this scale.

Design of data mining for analyzing of Big Data

Data mining is a process of extracting unknown knowledge with potential value from a data. The current modeling method of data mining is a three-step method, which is composed of sample– > modeling– > testing. The modeling is completed automatically by the algorithm and after the model is built, it will be tested by the user. If the test result is not satisfactory, training data and the algorithm parameters will be changed and a new model will be created by the improved algorithm. This method is not applicable to big data analytics, because big data have huge volume, many attribute parameters, cost longer modeling time, and the modeling result is often unsatisfactory.

In the work environment of the Weka system, this paper attempts to use the internet technology to realize cloud storage and cloud computing, and to optimize the original distributed mining algorithms, and manage mining algorithms, distributed and parallel databases through the visual system data preprocessing and the real-time memory monitoring. Through the interface document in the Weka system, K-means algorithm is integrated into this data mining platform to improve traditional data mining techniques so as to realize the analysis of big data. Fig. 1 shows the structural design.

Weka integrates multiple mature data mining algorithms, and provides the interfaces associated with the database system. With its open nature and Java-based cross-platform, Weka has become an important platform for learning and applying data mining algorithms.

Weka is a collection of machine learning algorithms for data mining tasks. The algorithms can eit her be applied directly to a dataset or called from your own Java code. Weka contains tools for data pre-processing, classification, regression, clustering, association rules, and visualization. It is also w ell-suited for developing new machine learning schemes。

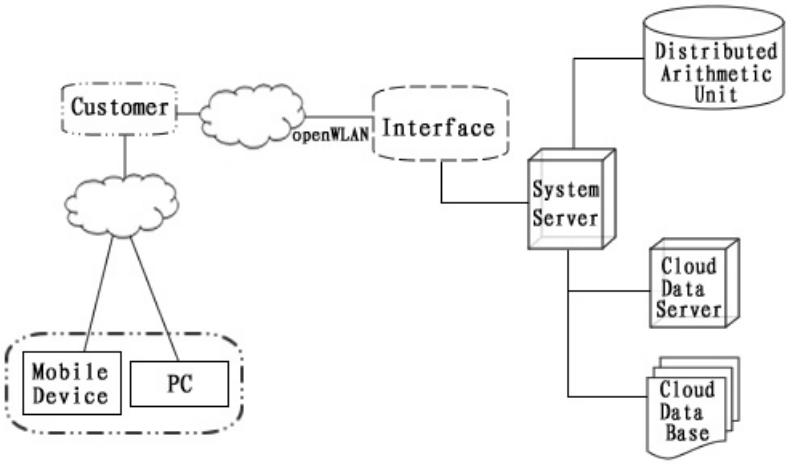

Fig1. Structure Diagram of Big Data mining Base on Weka Platform

Through the external interface of the system, users can input the big data to be analyzed from mobile devices and PC into this platform server. The big data will first be compressed and refined through the algorithm library of Weka platform and K-means clustering integration, and then analyzed by the dynamic expert intelligent system provided by the cloud data server and cloud data storage.

When the optimized data mining system mines in the item set with frequent association rules, the memory runs out obviously, and thus needs to be monitored in the operation of the design system. When the memory runs out, the original dataset needs to be decomposed and the decomposed datasets are mined. Finally, the mining results are merged to produce the final result. The working interface is shown in Fig. 2.

Integration of K-means clustering algorithm in Weka system

In the design working platform, a series of optimization is conducted on the traditional data mining algorithms and the core content is to analyze big data. Big data contain enormous association rules

and, if mined blindly, not only is the mining efficiency low, but lots of irrelevant rules may be found and many rules cannot be put to good use. In addition, data mining and knowledge discovery are hard and meticulous work, only the strict control of application scale can secure good effects in practical applications. The use of clustering to preprocess the data can help obtain the basic information of the data. If the original dataset is too big to be read into the memory for clustering at one time, the data in the dataset can first be recognized and then some data are generalized, or sample data can be used to represent the original dataset and clustering is conducted on the sample dataset. These two methods can realize the clustering of large-scale datasets and reduce the memory space occupied by the data. Feature extraction or classification based on this clustering improves its accuracy and mining efficiency. The clustering results can also be used for further association analysis to obtain more useful information. The realization of K-means algorithm integration through the interface program in the Weka system enables the effective application of traditional data mining techniques to big data analytics.

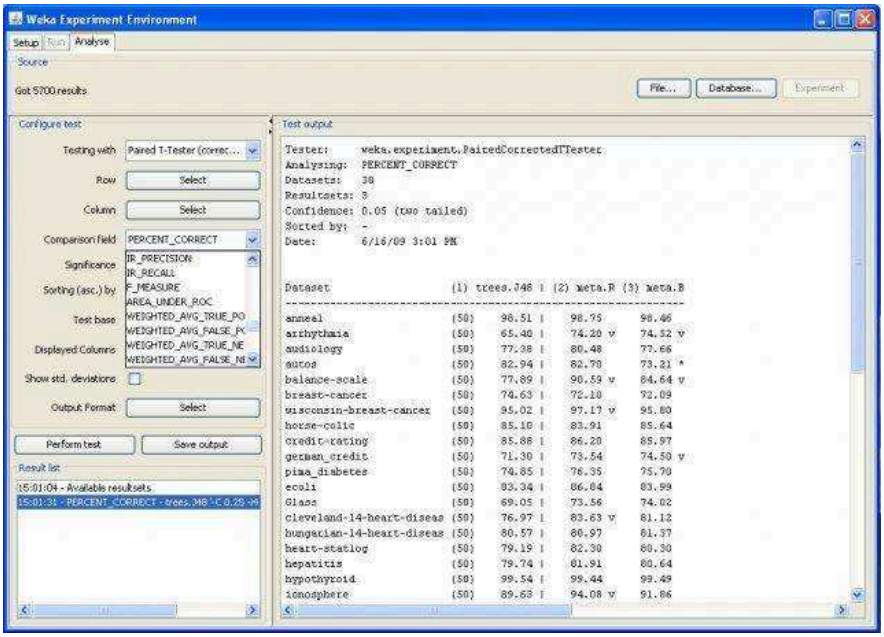

Fig2. Working interface of Weka platform

K-Means is a segmentation clustering method and its main aim is to find out representative data points from large quantities of high-dimensional data points. These representative data points can be called cluster centers, or representative points, according to which the subsequent processing is conducted. As is shown in Figure 3, this system operates as follows: firstly, some data points are read from the original large-scale dataset (random sampling can be used); secondly, these data points are read into the memory; thirdly, the data in the memory are clustered and the clustering model is updated; fourthly, the data points in the memory are recognized and differentiated according to this updated clustering model; Fifthly, the corresponding data are compressed and refined through the visual Weka platform and then clustered again. That is to say, K cluster centers are given and the sample points to be classified are allocated to the clusters according to the nearest neighbor principle; the average method is used to recalculate the centroid of each cluster to determine the new cluster center. The iteration continues until the displacement distance of the cluster centers is less than the given value. Then the update of the clustering model is ended and the results are output. This algorithm requires one scanning of the original dataset at most to finish the clustering process. If the original dataset is very large, the scanning will consume many resources. However, if the clustering model is discovered in advance, this algorithm can cut the clustering process short without scanning the whole dataset. This algorithm can reflect the features of the on-line clustering and conduct real-time clustering on the dataset and obtain the best clustering result. This algorithm can easily provide the clustering progress, time remaining and other information. When the memory space is not

stable, such clustering tasks as suspension, stop and restart can be easily performed, and incremental clustering can be conducted on the new data on the basis of the existing clustering results.

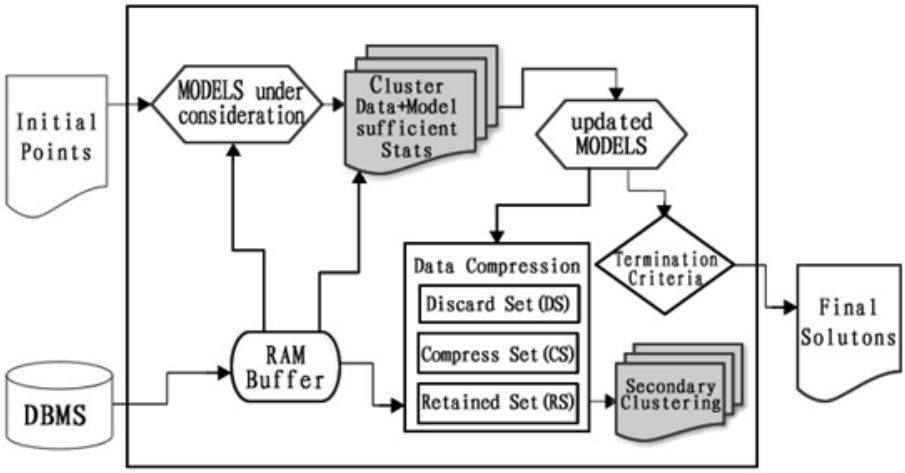

Fig 3 The main frame of k-means algorithm

Conclusions

In the Weka working environment, to use K-means algorithm for clustering analysis and ensemble can conduct the preprocessing of big data analytics and the real-time monitoring, and thus extends the traditional data mining techniques to the level of cloud storage and cloud computing. This algorithm can cluster large-scale datasets in the very low memory space and adopt various methods to read the original datasets, such as random sampling, sequential reading. It can use the cursor which only supports rolling forward to read the original datasets, which solves such problems of the cursor as the back-and-forth rolling, random positioning and more consumption of system resources. This is also important for the clustering of large-scale datasets. The further development of this optimized system will focus on in-depth studies on cloud storage and cloud computing.

Abstract. In this paper, the author designed the model of instruction expert system based on improved genetic algorithm and described the realization of improving exercises in detail. In this system, the students can online learn through different modes and receive the guidance from the teacher, meanwhile the analysis to effect the parameter of intelligent tests generating will be produced. So the following exercises focus on the student's weakness, this is useful to enhance the students' the knowledge level and operation ability.

0 Introduction

With the rapid development of network technology, the platform of engineering education has already expanded to rich resources and constantly updated web space. The instruction mode has been converted from the traditional tuitional teaching to the diversified teaching of network independence and exploring type. In this paper, the author designed the model of instruction expert system based on improved genetic algorithm, by which students can independently study on-line through intelligent guidance, so as to improve the students' knowledge level and operation ability.

1 Design of Instruction Expert System

1.1 Structure of Instruction Expert System

Expert system is an intelligent computer program system. There are a large of domain knowledge and experience in expert level inside and it can solve the problems in this field using the knowledge and methods used by human experts to solve problems. The system adopts B/S structure. There are four kinds of identities setted for login in the system, namely student, administrator, teachers and expert. The different identity makes the user own imparity permission and shoulder distinct responsibility. The independent study module of student (ISM) and the expert system module (ESM) make up the instruction expert system, that is shown in Figure 1.

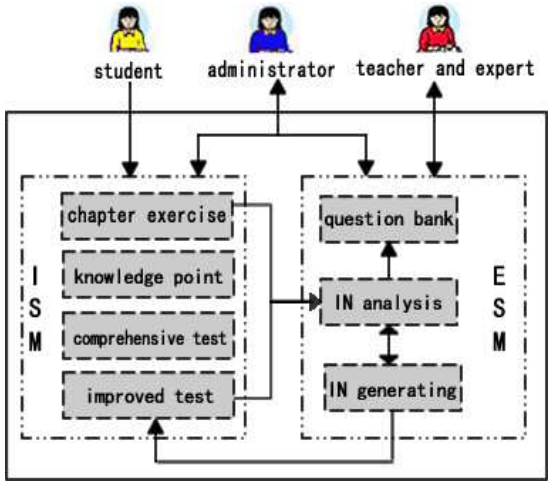

Figure 1. Structure of Instruction Expert System

1.2 ISM and ESM

Four pattern can be provided in ISM module when the student logins. He may select the pattern to exercise or test from chapter exercise, knowledge point exercise, comprehensive test and improved test. The performance will be evaluated by the system and be sent to the other module for intelligent analysis. ESM module includes three parts, namely question bank, intelligent analysis, and intelligent tests generating. The intelligent analysis module gives results based on the score of the student. The system modified the parameters and constraint condition of intelligent tests generating, so that increase the weight of error questions in upcoming study for improving learning efficiency.

2. Module Research of Intelligent Test Generating

Intelligent test generating module will produce the questions based on constraint condition in question bank. In other words, filtering for the question should be proceeded according to the properties. These are variable with the situations of the students' error rate and degree of difficulty. For a certain test, the module generates a exam paper with n questions, then five properties that can form a matrix for n*5 are ascertained, as shown in Table 1 and Table 2.

Table 1. Constraint Condition

Condition	Annotation
Number	Number in question bank
Queseion Type	Choice、Blank、Judge、Programe
Degree of Difficulty	d=1-avg/sum
Error Rate	t=error/sum
Score	This question's score

Table2. Properties Matrix

$$S=\begin{bmatrix} a11 & a12 & a13 & a14 & a15 \\ a21 & a22 & a23 & a24 & a25 \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ an1 & an2 & an3 & an4 & an5 \end{bmatrix}$$

3 Design of Instruction Expert System

3.1 The structure of genetic algorithm

Genetic algorithm is a search optimization algorithm based on biological simulation genetics and natural selection. The evolution process starts from initial population, determines fitness function, according to the assesses the fitness of each test case after the execution procedures. The higher fitness is the closer between test cases and the expected effect. Improve the test cases with crossover, mutation and choice- three basic operations. Evaluate the fitness function. The process will be over until the result is closest to the best expectation. Aiming at the specific situations of intelligent question grouping, we provide the following concrete improved solutions.

3.2 Determining coding scheme

The GA coding strategies have great impacts on genetic manipulation, and in many cases the coding forms determine genetic manipulation. Coding strategies shall basically meet three standards, namely completeness, soundness and non-redundancy. On this basis, when selecting test questions, we adopt the coding strategy of binary grouping to quickly selecting questions and reduce redundancy rate. In other words, the whole binary string is divided into different functional modules according to question types, and every functional module adopts independent binary coding.

3.3 Setting initial population

Question selecting is a restricted problem with multiple constraint objectives. In order to enhance the efficiency of GA and reduce the time for question selecting, we no longer use traditional GA to generate initial population randomly. Instead, we make initial population P_0 meet such constraint conditions as question types, total points of test paper and quiz time, which is in favor of enhancing the efficiency of question selecting.

3.4 Constructing fitness function

Fitness is an important indicator for describing individual performance in GA, while GA selects the superior and eliminates the inferior towards individuals according to fitness. Fitness function is used to evaluate the degree of excellence of individuals in a population and guide GA to finally find out the functions of the test data that cover the prescribed route. In the question selecting problem, according to every constraint condition, the objective function is defined as follows: $f=\sum_{i=1}^{5} f_i w_i$ .f_i stands for the absolute value of the error between i^{th} property indicator and user requirements, w_i stands for the weight of the i^{th} indicator on the degree of question, $w_i>0$, and f is the sum of the absolute value of the error between all indicators and user requirements. It can be seen from the above objective function that this problem is about optimization of minimum value. After the objective

function is changed appropriately, fitness function can be defined as: F= $\frac{1}{1+f}$ .If this fitness function is used to judge individual performance, then the smaller the error of individual's constraint condition towards question selecting is, the greater the fitness value will be and the better the individual performance will be; on the contrary, the greater the error of individual's constraint condition towards question selecting is, the smaller the fitness value will be and the worse the individual performance will be. In the process of evolution, adjusting fitness is fitness function scaling. We adopt exponential function scaling strategy, and after scaling the fitness function is: F'=exp(-βF).

3.5 Genetic operators

GA includes three basic genetic operators: selection operator, crossover operator and mutation operator. The operation methods or operation strategies of GA vary along with specific problems. In this problem, the genetic operators are mainly constrained by the following two conditions:

1) Coding strategies: we adopt the coding strategy of binary grouping in this paper;

2) Constraint conditions: we have meet part of constraint conditions when forming the initial population, such as the total points of test paper and proportion of question types. Genetic operators cannot break these already-met constraint conditions in the genetic process.

By the above two constraint conditions, genetic operators can be improved as follows:

Probability method that is proportional to fitness value is used to choose selection operators. The specific steps are: first, calculating the sum total ($\sum$f) of all fitness values in the population; then, calculating the proportion(fi/ $\sum$ f) of every individual's fitness value and taking it as the corresponding selection probability to figure out whether every individual has been selected.

For crossover operators, one-point crossover is adopted, so crossover can be done in same question types. In other words, a cross point is chosen according to the crossover probability, and only the segment where this point is located can be crossed. For example, in the crossover process of the two individuals below, A and B are the two individuals before crossover, A' and B' are two individuals after crossover, and it is supposed that the cross point is the second one on the second segment.

A =0101…|1110…|0110…|… B =1001…|0011…|1000…|…

A′=0101…|1011…|0110…|… B′=0101…|0110…|1000…|…

For mutation operators, we choose two-point mutation method, that is, to generate a mutation position according to the mutation probability, choose an inverse position from the beginning of this mutation segment and then exchange these two positions. In the following individual mutation process, one mutation position generated by the mutation probability is the third one on the second segment. A is the individual before mutation, and A′is the individual after mutation.

A=0101…|1010…|0110…|… A′=0101…|1100…|0110…|…

3.6 Determining Controling Parameters

Population size affect the final result and execution efficiency of genetic algorithm. When n number is small, the convergence speed will be fast, but it isn't easy to search the optimal solution. However if n number rises, the convergence speed will drop and the computational will be complicated. So n is from 10 to 160.

In this paper, fitness is used to measure the crossover probability and mutation bribability of self-adaptive adjustment of population diversity. The basic idea concerning self-adaptive GA operation is to make the crossover probability pc and mutation probability pm adjust at any time according to the real situations of the population during evolution. When individuals tend to be convergent, we should increase pc and pm, that is, to increase the probability of crossover and mutation to undermine the present stability and overcome premature convergence; when the individuals tend to be divergent, we should decrease pc and pm, that is, to reduce the probability of crossover and mutation to make the individuals convergent.

The self-adaptive crossover probability and mutation probability we adopt are as follows:

$pc=0.8\exp(-f/f_{avg})$……$f\geq f_{avg}$ $pc=0.8$……$f<f_{avg}$

$pm=0.01\exp(-f'/f_{avg})/f_{max}$……$f'\geq f_{avg}$ $pm=0.01$……$f'<f_{avg}$

favg：average fitness，f：two crossers fitness，f′：mutant fitness

Obviously fitness is used as the criterion for measuring the population diversity so as to make crossover probability and mutation probability automatically change along with the fitness. When the difference in individual fitness in a population is relatively small, we should increase crossover probability and mutation probability; when the individual fitness in a population is relatively divergent, we should decrease crossover probability and mutation probability.

Three termination conditions are adopted for question selecting in this paper: when the optimal solution is searched out; when the frequency of execution is reached; When the change rate of the maximum fitness value of two generations is less than the specified value, it can be regarded that population evolution is stable, tends to be convergent and terminated.

3.7 Experiment Analysis

In experiment，there are 600 questions containing four types of questions in bank. The parameters of GA: n=80, pc=0.8, pm=0.1, D=500, FS=100, Time=120.The results of two algorithms are shown as Fig.3. The conclusion can be drawn that the convergence of the improved genetic algorithm is more perfect and stable. Meanwhile the improved algorithm can guarantee the diversity of individuals and global search ability.

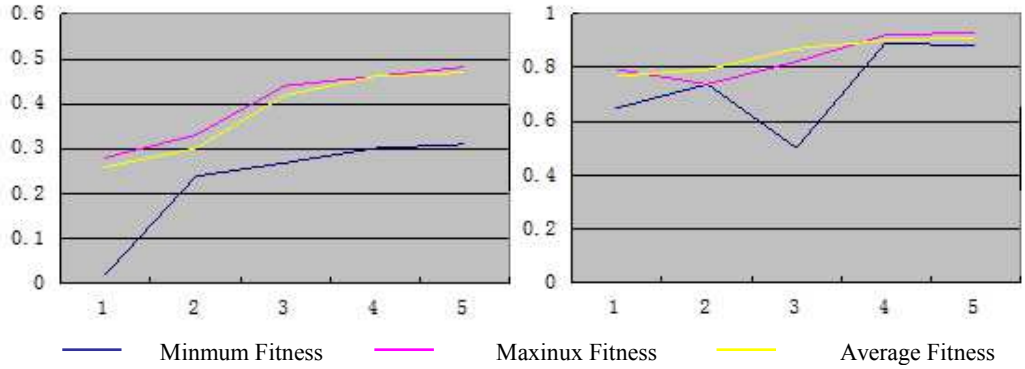

Fig.3 Comparision of simple GA and improved GA

Summary

In this paper, the author designed the model of instruction expert system based on improved genetic algorithm and described the realization of improving exercises in detail. Especial through comparing the simple genetic with the improved genetic, the conclusion can be drawn that the intelligent tests generating module may generate the question efficiently. So the following exercises focus on the student's weakness, this is useful to enhance the students' the knowledge level and operation ability. The research is still needed to make the automatic evaluation of various types of project design more accurately and efficiently.

Investor Selection Model under Uncertain Information Environment

Congjun Rao, Cheng Wang

College of Mathematics and Physics, Huanggang Normal University,

Huanggang 438000, China

cjrao@163.com

Keywords: Investor selection; Dual uncertainty information; Fuzzy grey number; Fuzzy grey deviation degree

Abstract. In this paper, the problem of selecting investor is studied under dual uncertainty information, i.e. fuzzy information and grey information. Concretely, a new index system of evaluating the investors which includes sales capacity, management capacity, throughput, technology capacity, fund capacity, risk capacity and uniformity of enterprise strategy is designed, and then a model of dual uncertainty multi-attribute decision making is proposed. Moreover an optimization algorithm of fuzzy grey deviation degree is present to solve this model.

Introduction

With the high development of economy, more and more people become self-employed worker. There are many people start a company independently. So to select the right investors is the key to business success for the self-employed worker. When selecting the investors, some attributes must be consided such as sales capacity, management capacity, throughput, technology capacity, fund capacity, and so on. But there are many uncertainties in the problems of decision making of selecting the investors because of the complication of the decision making systems. Oen the one hand, in practical decision making, the attribute variable of sales capacity, management capacity, et al. are usually given in the forms of linguistic fuzzy variable, such as “worst, worse, bad, common, good, better, best” or “lowest, lower, low, common, high, higher, highest ”[2-4] by the decision makers. We called this kind of uncertainty is subjective uncertainty, i.e. fuzzy information. One the other hand, due to some differences in knowledge frame, experience level, status and individual preference for the decision makers, there exist incomplete and inadequate information in the decision making problems, so the attribute values given by decision makers have a certain grey degree (Grey degree is the measurement to measure the insufficiency or unlikelihood of information [8]). We called this uncertainty is the objective uncertainty, i.e. grey information. Therefore, when we select the investors, we must consider not only the fuzzy information but also the grey information. So we can transform the decision making problem of selecting the investors into a multi-attribute decision making problems with dual uncertainty information, i.e., fuzzy information and grey information.

Nowadays, some scholars studied the problems of multi-attribute decision making with the fuzzy information[2-12], but the study on the problems multi-attribute decision making with both fuzzy information and grey information is few. From this current situation, and by considering the practical problem of selecting the optimal investors, we presents a new model of dual uncertainty multi-attribute decision making and gives optimization algorithm of fuzzy grey deviation degree to solve this new model. Therefore, this paper provides a new and effective way to deal with the multiple uncertainties in the problems of multi-attribute decision making.

The Problem Statement

Suppose that self-employed worker of an investment corporation wants to select some optimal investors. There are m alternatives take part in the competition, the set of alternatives is denoted as $X = \{X_1, X_2, \cdots, X_m\}$. Now we choose the following seven attributes forms the evaluation index

system, i.e., Sales capacity (A1), Management capacity(A2), Throughput (A3), Techno-logy capacity (A4), Fund capacity(A5), Risk capacity(A6) and Uniformity of Enterprise strategy(A7). The set of attributes is denoted as $A=\{A_1,A_2,\cdots,A_7\}$. Let $W=(w_1,w_2,\cdots,w_7)$ be the weightvector of these seven attribute, where w_j satisfies $0\le w_j\le 1,\ \sum_{j=1}^{n} w_j=1$.

Let the evaluation value of alternative $x_i\ (i=1,2,\cdots,m)$ on attribute $A_j\ (j=1,2,\cdots,7)$ which given by decision maker is a linguistic fuzzy variable s_{ij}, such as "worst, worse, bad, common, good, better, best" or "lowest, lower, low, common, high, higher, highest "with the grey degree v_{ij}, it denoted as a fuzzy grey number $e_{ij}=[s_{ij},v_{ij}]\ i=1,2,\cdots,m$, $j=1,2,\cdots,7$. All the evaluation values $e_{ij}=[s_{ij},v_{ij}]$ forms the original decision matrix $R=(e_{ij})_{m\times 7}$. Now from the information of the original decision matrix $R=(e_{ij})_{m\times 7}$, we the self-employed worker need to make evaluation and rank order for all alternatives, and select the optimal investors among all alternatives.

The Model

In this section, we will presents a new model of dual uncertainty multi- attribute decision making and gives optimization algorithm of fuzzy grey deviation degree to solve this new model. Firstly, some definitions are given.

Definition 1 Let the set of information content be $I=$ {very sufficient, sufficient, common, imcomplete, very imcomplete}, and the measurement of information content is measured by grey degree, the quantization method is as follows[8]:

very sufficient: 0～0.1, sufficient: 0.2～0.3, common: 0.4～0.6,

imcomplete: 0.7～0.8, very imcomplete: 0.9～1

the determinate values of grey degree can be determined with the practical problems of decision making.

Definition 2 Suppose that $S_a=$ {worse, bad, common, good, better}([2]) or $S_b=$ { lower, low, common, high, higher}([3]), then S_a and S_b are called the set of linguistic fuzzy variable, they are denoted as $S_a=\{s_1,s_2,\cdots,s_5\}$, $S_b=\{s_1',s_2',\cdots,s_5'\}$, and their corresponding interval numbers are defined as follows:

(i) For the type of cost attributes, we have

s_1=(0.8, 1); s_2=(0.7, 0.8); s_3=(0.6, 0.7); s_4=(0.5, 0.6); s_5=(0.3,0.5);

(ii) For the type of revenue attributes, we have

s_1=(0.3,0.5); s_2= (0.5,0.6); s_3=(0.6,0.7); s_4=(0.7,0.8); s_5=(0.8,1);

the corresponding triangle fuzzy numbers for S_b are the same as S_a.

Definition 3 Let $\tilde{a}=[b,c]$ be a interval number with the grey degree v, $v\in[0,1]$, then $\tilde{e}=(\tilde{a},v)$ is called a fuzzy grey number. If $v=0$, then $\tilde{e}$ is a genera interval number, and if $b=c$, then $\tilde{e}$ is a general real number.

Definition 4 Let $\tilde{e}_1=([b_1,c_1],v_1)$ and $\tilde{e}_2=([b_2,c_2],v_2)$ be two fuzzy grey numbers, the algorithms for $\tilde{e}_1$ and $\tilde{e}_2$ are defined as follows:

1) $\tilde{e}_1+\tilde{e}_2=[(b_1,c_1),v_1]+[(b_2,c_2),v_2]=[(b_1+b_2,c_1+c_2),(v_1+v_2)\wedge 1]$;

2) $k\tilde{e}_1=[(kb_1,kc_1,kd_1),(kv_1)\wedge 1)]$, $k\ge 0$.

Definition 5 Let $\tilde{e}_1=([b_1,c_1],v_1)$ and $\tilde{e}_2=([b_2,c_2],v_2)$ be two fuzzy grey numbers, the distance from $\tilde{e}_1$ to $\tilde{e}_2$ is defined by

$$D(\tilde{e}_1,\tilde{e}_2)=\frac{1}{2}(|b_1-b_2|+|c_1-c_2|+|v_1-v_2|)$$

According to the above definitions, we can obtain the decision making matrix, it denoted as $\overline{Z}=([b_{ij},c_{ij}],v_{ij})_{m\times 7}$, $i=1,2,\cdots,m$, $j=1,2,\cdots,7$.

From the decision making matrix $\overline{Z}$, a new optimization algorithm of fuzzy grey deviation degree is given to rank order for all alternatives. The definition of fuzzy grey ideal solution is given in the following Definition 8.

Definition 6 Let $\overline{Z}=([b_{ij},c_{ij}],v_{ij})_{m\times 7}$ be a decision making matrix. Then $\overline{y}^{+}=(\overline{y}_1^{+},\overline{y}_2^{+},\cdots,\overline{y}_7^{+})$ is called a fuzzy grey positive ideal solution, and $\overline{y}^{-}=(\overline{y}_1^{-},\overline{y}_2^{-},\cdots,\overline{y}_7^{-})$ is called a fuzzy grey negative ideal solution, where

$$\overline{y}_j^{+}=([\overline{b}_j^{+},\overline{c}_j^{+}],v_j)=([\max_i b_{ij},\ \max_i c_{ij}\ ],\min_i v_{ij}), \tag{1}$$

$$\overline{y}_j^{-}=([\overline{b}_j^{-},\overline{c}_j^{-}],v_j)=([\min_i b_{ij},\ \min_i c_{ij}],\max_i v_{ij}), \tag{2}$$

Based on the distance from fuzzy grey numbers $\tilde{e}_1$ to $\tilde{e}_2$ in definition 5 and the fuzzy grey ideal solution in definition 6, we define the fuzzy grey deviation degree as follows.

Definition 9 Let $\overline{y}^{+}=(\overline{y}_1^{+},\overline{y}_2^{+},\cdots,\overline{y}_7^{+})$ and $\overline{y}^{-}=(\overline{y}_1^{-},\overline{y}_2^{-},\ \cdots,\overline{y}_7^{-})$ be the fuzzy grey positive ideal solution and fuzzy grey negative ideal solution, respectively, and let $\overline{Z}_i=(\overline{z}_{i1},\overline{z}_{i2},\ \cdots,\overline{z}_{i7})$ be the i-th alternative point, where

$$\overline{Z}_i=(\overline{z}_{i1},\overline{z}_{i2},\cdots,\overline{z}_{in})=(([b_{i1},c_{i1}],v_{i1}),([b_{i2},c_{i2}],v_{i2}),\cdots,([b_{i7},c_{i7}],v_{i7}), \tag{3}$$

Suppose that

$$\sigma(\overline{y}^{+},\overline{Z}_i)=w_1D(\overline{y}_1^{+},\overline{z}_{i1})+w_2D(\overline{y}_2^{+},\overline{z}_{i2})+\cdots+w_nD(\overline{y}_n^{+},\overline{z}_{i7}), \tag{4}$$

$$\sigma(\overline{y}^{-},\overline{Z}_i)=w_1D(\overline{y}_1^{-},\overline{z}_{i1})+w_2D(\overline{y}_2^{-},\overline{z}_{i2})+\cdots+w_nD(\overline{y}_n^{-},\overline{z}_{i7}), \tag{5}$$

Then $\sigma(\overline{y}^{+},\overline{Z}_i)$ is called the fuzzy grey deviation degree between the *i*-th alternative point $\overline{Z}_i$ and the fuzzy grey positive ideal solution $\overline{y}^{+}$, and $\sigma(\overline{y}^{-},\overline{Z}_i)$ is called the fuzzy grey deviation degree between the *i*-th alternative point $\overline{Z}_i$ and the fuzzy grey negative ideal solution $\overline{y}^{-}$, where w_j is the weight of the *j*-th attribute, $j=1,2,\cdots,7$. $D(\overline{y}^{+},\overline{z}_{ij})$ is the distance from $\overline{y}_j^{+}$ to $\overline{z}_{ij}$, and $D(\overline{y}_j^{-},\overline{z}_{ij})$ is the distance from $\overline{y}_j^{-}$ to $\overline{z}_{ij}$, they are expressed as

$$D(\overline{y}_j^{+},\overline{z}_{ij})=\frac{1}{2}(\left|\max_i b_{ij}-b_{ij}\right|+\left|\max_i c_{ij}-c_{ij}\right|+\left|\min_i v_{ij}-v_{ij}\right|),$$

$$D(\overline{y}_j^{-},\overline{z}_{ij})=\frac{1}{2}(\left|\min_i b_{ij}-b_{ij}\right|+\left|\min_i c_{ij}-c_{ij}\right|+\left|\max_i v_{ij}-v_{ij}\right|).$$

For the fuzzy grey deviation degree $\sigma(\overline{y}^{+},\overline{Z}_i)$ and $\sigma(\overline{y}^{-},\overline{Z}_i)$, the smaller the value of $\sigma(\overline{y}^{+},\overline{Z}_i)$ is, the better the alternative $\overline{Z}_i$ is, and the greater the value of $\sigma(\overline{y}^{-},\overline{Z}_i)$ is, the better the alternative $\overline{Z}_i$ is. From $\sigma(\overline{y}^{+},\overline{Z}_i)$ and $\sigma(\overline{y}^{-},\overline{Z}_i)$, we give the following approach degree u_i, where

$$u_i=\frac{\sigma^2(\overline{y}^{+},\overline{Z}_i)}{\sigma^2(\overline{y}^{+},\overline{Z}_i)+\sigma^2(\overline{y}^{-},\overline{Z}_i)}$$

We can rank order for all alternatives according to the values of u_i. The smaller the value of u_i is, the better the alternative x_i is.

The Decision Making Steps

From above discussion, here we give the detail steps for solving the problems of selecting optimal investors under uncertain information environment.

Step 1: For m decision alternatives, determining fuzzy grey matrixes by the decision maker, which denoted as $R=(e_{ij})_{m\times 7}$.

Step 2: Use Definition 1 and Definition 2, we can obtain the decision making matrix, it denoted as $\overline{Z}=([b_{ij},c_{ij}],v_{ij})_{m\times 7}$, $i=1,2,\cdots,m$, $j=1,2,\cdots,7$.

Step 3: Use formula (1) and formula (2) to determine the fuzzy grey positive ideal solution $\overline{y}^{+}$ and fuzzy grey negative ideal solution $\overline{y}^{-}$, and by using formula (3) to determine the alternative point $\overline{Z}_1,\overline{Z}_2,\cdots,\overline{Z}_m$ from matrix $\overline{Z}$, respectively.

Step 4: Calculate the deviation degree $\sigma(\overline{y}^{+},\overline{Z}_i)$ and $\sigma(\overline{y}^{-},\overline{Z}_i)$, $i=1,2,\cdots,m$.

Step 5: Calculate the approach degree u_i, $i=1,2,\cdots,m$.

Step 6: Ranking order for all alternatives according to u_i, and selection the optimal investors.

Conclusions

In this paper, we investigate the problem of selecting investor under fuzzy information and grey information, and then a decision making model is proposed based on the theories of fuzzy mathematics and grey system is presented, and the optimization algorithm of fuzzy grey deviation degree is given for solving this new model. This new model is specific, fine in properties and simple for computing, and it has a great theoretic value and applied value in practice. It provides a new and effective way to deal with the multiple uncertainties in the problems of multi-attribute decision making.

Keywords: Memetic Algorithms;Nutrition Prescription;Invasive Weed Optimization;Differential Evolution Optimal Design

Abstract. In this paper ,we discuss multiobjective optimization problems solved by Memetic algorithms. We present A novel multiobjective memetic algorithm based on invasive weed optimization and differential evolution(IWO-DE) to solve this class of problems .We present the Nutrition Prescription Model for Meals.the IWO-DE is applied to solve the nutrition decision making problem to map the Pareto-optimum front. The results in the problem show its effectiveness.

Introduction

The nutrition meal model is multi-objective, whose goal function is a vector. In a multiobjective optimization problem (MOP), there may not exist one solution that is best with respect to all objectives. Usually, the aim is to determine the tradeoff surface, which is a set of nondominated solution points,known as Pareto-optimal or noninferior solutions. In view of the fact that none of the solutions in the nondominated set is absolutely better than any other, any one of them is an acceptable solution.

Since the work of Schaffer [1] a considerable number of different Multiobjective Optimization Evolutionary Algorithms (MOEAs) have been suggested .Deb and co-authors [2] suggested an elitist non-dominated sorting GA (called NSGA-II). Zitzler and Thiele [3] suggested a Strength Pareto EA (SPEA) . Recently SPEA was modified in order to incorporate a fine-grained fitness assignment strategy, a density estimation technique and an enhanced archive truncation method – SPEA2 algorithm [4]. Meanwhile a number of other multiobjective evolutionary algorithms have been proposed, such as the algorithm of Knowles and Corne[5,6] , which is based on an evolution strategy.

In this paper, we present the Nutrition Prescription Model for meals. Moreover, we present the IWO-DE and we analyze it regarding the solution of MOPs. Finally,we apply the IWO-DE to solve the Nutrition Prescription problem with the aim of find the optimum tradeoff surface.In the experiment,we obtain optimized solutions using the IWO-DE.

A Multiobjective Memetic Algorithm based on Invasive Weed Optimization and Differential Evolution(IWO-DE)

IWO

IWO is first presented by Mehrabian and lucas [7] to solve numerical optimization problems. IWO simulates the nature principles and behaviors of weedy invasion and colonization in the shifting and turbulent environment. Later, Kundu et al. [8] proposed a variant of IWO that extends the original IWO to handle multi-objective optimization problems. Generally speaking, there are four steps of IWO.

1. Initialize a population: solutions are initialized and dispersed in the given n dimensional search space uniformly and randomly.

2. Reproduction: each individual of the population is permitted to reproduce seeds according to its own fitness, the colony's lowest and highest fitness, in this situation, the fitness of each

individual is normalized and the number of seeds each individual reproduces depends on a given minimum and maximum and increases linearly.

3. Spatial dispersal: offspring are randomly distributed over the n dimensional search space by normally distributed random numbers with mean equal to zero; but varying variance. Through this, a group of offspring are produced around their parent individual and thus weed colony is formed to enhance the search ability. Furthermore, standard deviation (sd) of the normally distributed random function will be reduced from a predefined initial value, sd_{max}, to a final value, sd_{min}, over every generation. the value of sd for a given generation is computed as follows.

$$sd=(sd_{max}-sd_{min})*(iter_{max}-iter)_m iter_{m\ max}+sd_{min} \quad (1)$$

where $iter_{max}$ is the maximum number of generations, iter is the current number of generation and m is the nonlinear modulation index.

4. Competitive exclusion: with the growth and reproduction of weeds, after passing several generation, the number of weeds in a colony will reach its maximum. Therefore, an essential exclusion mechanism is needed among weeds. The exclusion mechanism is applied to eliminate weeds with low fitness and select good weeds that reproduce more than undesirable ones. Subsequently, the selected ones will be preserved into the next generation and then the steps I-IV are repeated until termination criterion is reached.

Differential evolution

DE, proposed by Storn and Price [9], is a powerful search algorithm in the optimal problems, and uses the vector differences of individuals for perturbing the population members.

Initially, DE comprises a population of N and every individual is an n-dimensional vectors $x_i=\{x_1,x_2,\ldots,x_n\}$. These vectors are randomly generated in the search space and in the process of evolution, individuals will be tackled by the operations of mutation, crossover and selection.

Mutation operation: in this operation, with the different mutant strategies, the generated way of a mutant vector v_i is different and the weighted vector difference of individuals is various. The popular mutant strategies are summarized as follows.

$$DE_{rand1}: v_i=x_{r1}+F(x_{r2}-x_{r3}) \quad (2)$$

$$DE_{rand2}: v_i=x_{r1}+F(x_{r2}-x_{r3})+F(x_{r4}-x_{r5}) \quad (3)$$

where the subscript r_1, r_2, r_3, r_4, r_5, which are all different from the index i, are not equal to each other and selected uniformly and randomly from the range [1, N]. x_{best} is the best individual of the current population, F is a scaling factor that measure the scale of the difference of vectors.

Crossover operation: with the mutant vector v_i and the target vector x_i, the trial vector u_i is generated by binomial crossover as follows.

$$u_{i,j}=\{v_{i,j},\text{if } jrand\le C_r \text{ or } j=jrand \quad x_{i,j},otherwise\} \quad (4)$$

where $i=1,2,\ldots,N, j=1,2,\ldots,n, jrand$ is a selected integer randomly from [1, n] which ensures u_i inherits at least one component from the mutant vector v_i, randj is a uniform random number between 0 and 1. C_r is the crossover probability parameter and its value is within [0, 1].

Selection operation: to keep better individual into next generation, the generated trial vector u_i is compared with the target vector x_i. The selection operation is described as follows.

$$x_{i,G+1}=\{u_{i,G},\text{if } f(u_{i,G})\le f(x_{i,G}) \quad x_{i,G},otherwise\} \quad (5)$$

After the refinement procedures of IWO, the elitist individuals are picked out. Therefore, the operations of DE are applied among the selected elitist individuals to explore more promising space for the aim of finding out more promising solutions to be refined by IWO.

IWO-DE

For each component of IWO-DE, the attracting characteristics of IWO and DE is merged. That is, for IWO, the characteristics refers to the point that each individual fully exploits the useful information around it and for DE, the excellent characteristics refers to making full use of information provided by IWO to find out more valuable individuals which are to be refined, in return, by IWO.

The whole framework of IWO_DE is presented in Algorithm 1.

Algorithm 1 The whole framework of IWO-DE

step1:t=1;

step2:generate an initial population P_0 uniformly and randomly within lower and upper boundary of decision variable;
step3:F_0=evaluate(P_0);
step4:while termination condition is false do
step5:P_t=IWO(P_{t-1},F_{t-1});
step6:F_t= evaluate(P_t);
step7:[P_t, F_t]=DE(P_t, F_t);

step9:end while

Test results

Mould and method of optimization for nutrition decision makinings

The saying is that there is not bad food in the world but poorly-balanced food. To provide different groups with correspondingly well-balanced food, we design a balanceable nutrition meal model according to threpsology theorem[10]. The balanceable meal model is as follows：

$$\min F(X)=(f_1(X), f_2(X), \dots , f_k(X))^T \tag{6}$$

$$A=\begin{Bmatrix} a_{11}\ a_{12}\dots a_{1p}\ a_{1(p+1)} & \dots a_{1(p+q)}\ a_{1(p+q+1)}\dots a_{1n} \\ a_{21}\ a_{22}\dots a_{2p}\ a_{2(p+1)} & \dots a_{2(p+q)}\ a_{2(p+q+1)}\dots a_{2n} \\ \dots \quad \dots & \\ a_{m1}\ a_{m2}..a_{mp}\ a_{m(p+1)}\dots a_{m(p+q)} & a_{m(p+q+1)}\dots a_{mn} \end{Bmatrix}$$

$$X=(x_1,x_2,\dots,x_n)^T \qquad B=(b_1,b_2,\dots,b_m)^T$$

$$f_j(X)=\left|b_j-\sum_{i=1}^{n}a_{ij}x_i\right| \qquad j=1,2,\cdots,k \tag{7}$$

Where $f_1(X)$, $f_2(X)$, … , $f_k(X)$ are k the objectives functions,and Xi represents the weight of each raw food material, n the number of raw materials, aij the amount of nutrient in unit raw material, bi the standard of supply of each nutrient. In fact, absolute balance of each nutrient is difficult to achieve, but only to approach the supply standard. 1 to p is the food for breakfast, while p +1 to p+q is for lunch and p +q +1 to n for dinner. In actual life, people's standard nutrition demand is not always a specific value, but changing within a range,see equation (8).

$$1.1*bj=>\sum_{i=1}^{n} aijXi >=0.9*bj \tag{8}$$

Optimization in nutrition decision makinings

The nutrition decision making Problem was chosen to show the application of IWO-DE described in the previous study in solving a multiobjective nutrition optimization problem. In this paper, we search to find the Pareto-optimal front of a nutrition decision making .The aim is to find the multiple Pareto-optimal points considering two objective functions: 1) the first objective considers the energy and 2) the second one takes into account the protein . The constraint conditions are the bounds in the design variables. .

The problem was solved considering seven design variables in continuous case . The nondominated points have been found using IWO-DE method (with roulette wheel selection,and) coupled with a finite element code for energy and protein calculations. The domain was subdivided in these elements of first order.The results are presented in Figs.1 .

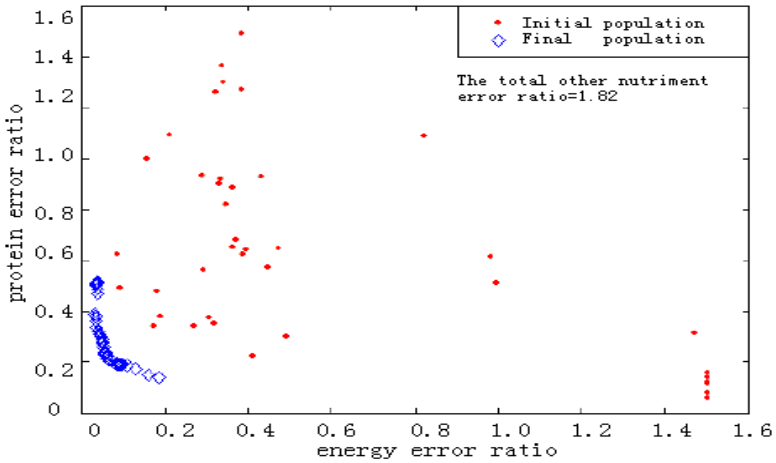

Fig. 1. Pareto-optimal points for the nutrition decision making proble

Conclusion

In this paper, the IWO-DE is presented for multiobjective optimization problems. The IWO-DE is applied to solve the nutrition decision making problem to map the Pareto-optimum front. The results in the problem show its effectiveness.For future work, we intend to test the algorithm on more problems.

Keywords: genertic algorithm; gene index; text clustering

Abstract. The genetic algorithm (GA) is a self-adapted probability search method used to solve optimization problems, which has been applied widely in science and engineering. In this paper, we propose an improved variable string length genetic algorithm (IVGA) for text clustering. Our algorithm has been exploited for automatically evolving the optimal number of clusters as well as providing proper data set clustering. The chromosome is encoded by special indices to indicate the location of each gene. More effective version of evolutional steps can automatically adjust the influence between the diversity of the population and selective pressure during generations. The superiority of the improved genetic algorithm over conventional variable string length genetic algorithm (VGA) is demonstrated by providing proper text clustering.

Introduction

Today, text clustering has become an important research topic to solve information overload problems in the field of information processing [1][2][3]. Clustering is an unsupervised pattern classification technique which is defined as group n objects into m clusters without any prior knowledge. In most real life situations the number of clusters in a data set is not known in advance. The real challenge is to be able to automatically evolve a proper number of clusters. Genetic algorithms (GAs) [4] based on the principle of evolution and heredity, are able to search in complex, large and multimodal landscapes. We can apply the searching capability of GAs to evolving proper number of clusters and providing appropriate clustering. A variable string length genetic algorithm (VGA) provided in [5][6] employs simple chromosomes to evolve the number of clusters. However, the compact chromosome encoding causes reduction of chances of getting the optimal centers combination. We propose an improved variable length genetic algorithm (IVGA) using gene indices to encode the chromosomes which have more chance to obtain the special centers combination and find the optimal number of clusters. We also propose dynamic evolutional steps to evolve. The details of the algorithm are described in section 4. Experiment results are given in section 5. Discussion and conclusions are given in section 6.

Clustering Model and Measure

Clustering is the classification of objects into different groups, or more precisely, the partitioning of a dataset into groups (clusters), so that the data in the same group are similar among themselves, and collectively different from the data of other groups. Generally, the distance measure between objects can be used to determine the similarity between them; a formalized description of the clustering model is as follows:

Given a dataset $X = \{x_1, x_2,\ldots, x_n\}$, for $\forall i \in \{1, 2,\ldots, n\}$, $xi = \{x_{i1}, x_{i2},\ldots, x_{ip}\}$ is an object in X and for $\forall t \in \{1, 2,\ldots, p\}$, x_{it} is an attribute of x_i. According to the inner feature of objects, X can be grouped into clusters $C = \{C_1, C_2,\ldots, C_k\}$, where $\bigcup_{i=1}^{k} C_i = X$, $\forall i, j \in \{1, 2,\ldots, k\}, C_i \neq \Phi$, $C_j \neq \Phi$, and $C_i \wedge C_j = \Phi$ $(i \neq j)$. $K = \{X, C\}$ is called a clustering space, C_i is the ith cluster in the clustering space.

There have been several suggestions for a measure of the similarity between two clusterings. Such a measure can be used to compare how well different data clustering algorithms perform on a

set of data. F-Measure [7], which combines precision and recall, is an index of system performance in information retrieval field. The precision P and recall R of cluster j and classification i are defined as

$$p = \frac{N_{ij}}{N_i}, \quad R = \frac{N_{ij}}{N_j} \tag{1}$$

where N_{ij} is the number of objects in cluster j subordinated to classification i; N_i is the number of all objects in classification i; N_j is the number of all objects in cluster j. The formula of F-Measure is as follows:

$$F(i) = \frac{2PR}{P+R} \tag{2}$$

Thus, the evaluation function of clustering results is defined as

$$F - Measure = \frac{\sum_i N_i F(i)}{\sum_i N_i} \tag{3}$$

A greater F-Measure means better clustering results.

Genetic Algorithms for Clustering

GAs are able to search in complex, large and multimodal landscapes. The parameters in the search space are represented in the form of chromosome. A collection of such chromosomes is called population. An objective and fitness function is associated with each chromosome that represents the degree of fitness. Biologically inspired operators like selection, crossover and mutation are applied to yield new child chromosomes. These operators continue several generations till the termination criterion is satisfied. The fittest chromosome seen up to the last generation provided the best solution to the clustering problem. We improved VGA chromosome using gene index to indicate the location of each gene. Such method is described in the next section.

IVGA for Text Clustering

Encoding Chromosome. In IVGA clustering, each chromosome C_i in the population initially encodes a number of K_i centers which are chosen randomly from the data set. These points are distributed in the random positions of the chromosome. We use gene index to denote the relative position of each point. Let us consider the following example.

Example: Let the random number K_i and K_j be 4 and 5 for chromosome C_i and chromosome C_j respectively. The VGA chromosomes encoding are shown as follows, C_i [Z_{i1}, Z_{i2}, Z_{i3}, Z_{i4}] and C_j [*Zj1, Zj2, Zj3, Zj4, Zj5*]. We know that a random exchange point crossover happened in VGA makes their offspring hold the same length as their parents. For example, if the crossover point is 3 their offspring generated are as follows, C_i' [Z_{i1}, Z_{i2}, Z_{i3}, Z_{j4}, Z_{j5}] and C_j' [Z_{j1}, Z_{j2}, Z_{j3}, Z_{i4}]. IVGA uses gene index to indicate the position of each gene. We generate a string of random numbers for gene locations. When random numbers are [0, 3, 4, 8] and [0, 2, 6, 7, 9], the C_i and C_j are shown as:

C_i: [Z_{i1}, Z_{i2}, Z_{i3}, Z_{i4}] gene index: [0, 3, 4, 8]

C_j: [Z_{j1}, Z_{j2}, Z_{j3}, Z_{j4}, Z_{j5}] gene index: [0, 2, 6, 7, 9]

If the crossover point is 5, we only need to exchange the genes whose gene index is greater than 5. The offspring generated are shown as:

C_i': [Z_{i1}, Z_{i2}, Z_{i3}, Z_{j3}, Z_{j4}, Z_{j5}] gene index: [0, 3, 4, 6, 7, 9]

C_j': [Z_{j1}, Z_{j2}, Z_{i4}] gene index: [0, 2, 8]

We can find that the lengths of offspring are different from their parents. So IVGA chromosome provides more chance to evolve proper number of clusters.

Evolution Principle of IVGA. We chose dynamic evolutional steps to evolve, which is shown in Fig. 1. The termination criterion is iteration of best fitness value without improvement exceeding consecutive N_{max} iterations. The criterion I happens when there have been no improvements in best fitness value for consecutive n_{max} iterations. The fittest concept selection, classical single-point

crossover and Gaussian Mutation [8] are adopted in this paper. Fitness function is defined to be 1/DB, where DB is Davies-Bouldin index [2, 9].

In Fig. 1, M is the size of population ; r and m are the proportion of chromosomes to crossover and mutation respectively.

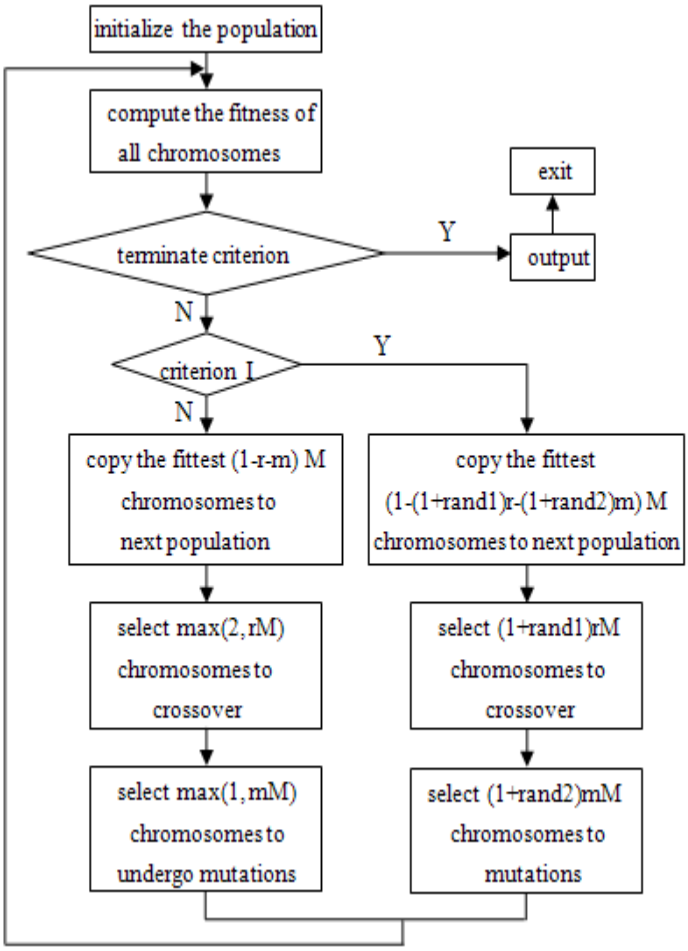

Fig.1. Dynamic evolutional steps of IVGA

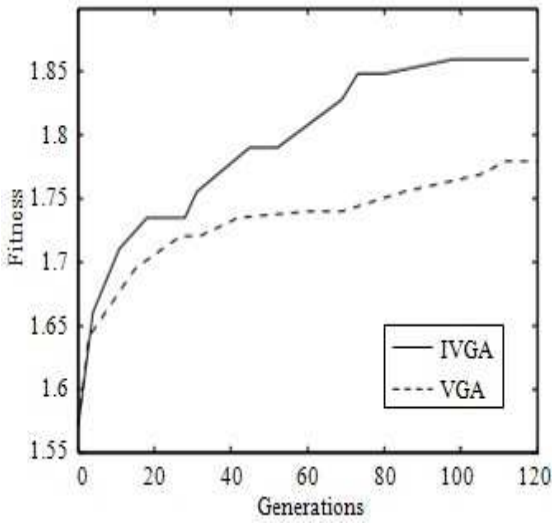

Fig.2. The fitness of IVGA and VGA for each generation

Experiments and Results

The dataset is extracted from the universal standard text collection, Reuters-21578, in which the documents were collected from Reuters newswire in 1987. 135 different categories have been assigned to 21578 Reuter documents. We chose 780 documents from it as dataset which includes five topics (gold, crude, interest, ship, sugar).

Vector space model is use here; each document is converted from the original format (i.e., strings of characters) to a word vector, (w_1, w_2,…, w_n), where w_i is the weight of the ith word. Information gain (IG) based approach is used as feature selection method, and the threshold is set as 0.4, which means that the IG value of each word lower than this threshold will be discarded. After being processed by word extraction, stop words removal, and stemming, there are 5,453 terms in the vocabulary. The IVGA is implemented with the following parameters: r = 0.4, m = 0.15, N_{max} = 20, n_{max} = 15 and the population size is 100. We then applied IVGA and VGA to clustering respectively. IVGA obtained 6 clusters, while VGA only got 4 clusters in the end. We used precision, recall and F-measure to evaluate the clustering results. Precision of cluster C_i is defined to be the number of texts correctly assigned divided by the total number of texts in cluster C_i. We define Recall of cluster C_i to be the number of texts correctly assigned divided by the total number of texts that should be assigned. Let P be average precision. Let R be average recall. F-measure is defined to be $2RP/(R+P)$. Table 1 shows the evaluation of IVGA and VGA.

Table 1. The Precision, Recall and F-measure of IVGA and VGA

Name	Precision	Recall	F-measure (%)
IVGA	77.2	73.8	75.5
VGA	54.7	71.4	61.9

To clustering problem, the real evaluation criterion is the fitness function 1/DB (Davies-Bouldin index). We choose the fitness of the best chromosome in each generation to represent generation fitness. In Fig. 2 the final fitness of 1.86 provided by IVGA is superior to that of VGA. Moreover, IVGA ends with fewer generations.

Conclusion

We proposed an improved variable string length genetic algorithm named IVGA for text clustering. The chromosomes with gene indices have been used for evolving the proper clustering. We also defined dynamic evolutional steps to evolve. We chose data set (780 documents, 5 topics) from the Reuter set for the tests. The results showed that not only did the IVGA evolve a more proper number of clusters, but also provided the appropriate clustering when compared with those of VGA. Since IVGA takes comparatively longer time to evolve the optimal clustering in high dimensional space, the correlative work of reducing the time complexity is being performed.

Keywords: Iterative method; nonlinear equation; Newton's method; efficiency index; order of convergence.

Abstract. With the rapid development and wide applications of information science and applied technology, nonlinear problems become an important direction of research in the field of numerical analysis. In this paper, we mainly study the iterative method for nonlinear equations. We propose and analyze a modified Newton-type method with order of convergence six for solving nonlinear equations. The method is free from second derivatives. The efficiency index of the presented method is 1.565, which is better than that of the classical Newton's method 1.414. Some numerical experiments illustrate the efficiency and performance of the proposed method.

1. Introduction

Nonlinear problems are an important direction of research in the field of numerical analysis. The solution of nonlinear equations is one of the most investigated topics in applied mathematics, numerical analysis, and the problem of solving nonlinear equations by numerical methods has gained more and more importance than before, since many practical problems in the applied information technology, as well as in materials science, manufacturing technology, can build a suitable mathematical model, and then be transformed into nonlinear equations to solve.

In this paper, in order to improve the efficiency, we consider iterative method to find a simple root x^* of a nonlinear equation

$$f(x)=0, \tag{1}$$

where $f:\Gamma\subseteq R\to R$ for an open interval Γ is a scalar function and it is sufficiently differentiable in a neighborhood of x^*.

It is well known that the classical Newton's method (NM for short) is a basic and important method for solving non-linear equation [1] by the iterative scheme

$$x_{n+1}=x_n-\frac{f(x_n)}{f'(x_n)} \tag{2}$$

which is quadratically convergent in the neighborhood of x^*.

In recent years, much attention has been given to develop iterative methods for solving nonlinear equations and a vast literature has been produced [2-7].

Motivated and inspired by the on going activities in this direction, in this paper, we present a sixth-order convergent iterative method. The proposed method is free from second derivatives. Several numerical results are given to illustrate the efficiency and advantage of the algorithm.

2. The Modified Iterative Method and Its Convergence Analysis

Let us consider the following iterative scheme.

Algorithm 1. For given x_0, we consider the following iteration scheme

$$y_n = x_n - \frac{f(x_n)}{f'(x_n)}, \tag{3}$$

$$z_n = x_n - \frac{2f(x_n)}{f'(x)+f'(y_n)}, \tag{4}$$

$$x_{n+1} = z_n - \frac{2f'(x_n)^2}{f'(x_n)^2 - 4f'(x_n)f'(y_n) + f'(y_n)^2}\frac{f(z_n)}{f'(x_n)}. \tag{5}$$

Theorem 1. Assume that the function $f:\Gamma \subseteq R \to R$ has a single root $x^* \in \Gamma$, where Γ is an open interval. If $f(x)$ has first, second and third derivatives in the interval Γ, then Algorithm 1 is sixth-order convergent in a neighborhood of x^* and it satisfies error equation

$$e_{n+1} = -\frac{3}{2}c_2(c_3 + 2{c_2}^2)(5c_3 - 6{c_2}^2)e_n^6 + O(e_n^7),$$

where $e_n = x_n - x^*$, $c_k = \frac{f^{(k)}(x^*)}{k!f'(x^*)}, k = 1,2,\cdots$.

Proof. Let x^* be the simple root of $f(x)$, $c_k = \frac{f^{(k)}(x^*)}{k!f'(x^*)}, k = 1,2,\cdots$ and $e_n = x_n - x^*$. Consider the iteration function $F(x)$ defined by

$$F(x) = z(x) - \frac{2f'(x)^2}{2f'(x)^2 - 4f'(x)f'(y(x)) + f'(y(x))^2}\frac{f(z(x))}{f'(x)} \tag{6}$$

where

$$z(x) = x - \frac{2f(x)}{f'(x)+f'(y(x))},\ y(x) = x - \frac{f(x)}{f'(x)}.$$

By some computations using Maple we can obtain

$$F(x^*) = x^*,\ F^{(i)}(x^*) = 0, i = 1,2,3,4,5,$$

$$F^{(6)}(x^*) = -\frac{5f^{(2)}(x^*)[f'(x^*)f^{(3)}(x^*) + 3f^{(2)}(x^*)^2][5f'(x^*)f^{(3)}(x^*) - 9f^{(2)}(x^*)^2]}{2f'(x^*)^5}. \tag{7}$$

Furthermore, from the Taylor expansion of $F(x_n)$ around x^*, we get

$$x_{n+1} = F(x_n) = F(x^*) + F'(x^*)(x_n - x^*) + \frac{F^{(2)}(x^*)}{2!}(x_n - x^*)^2 + \frac{F^{(3)}(x^*)}{3!}(x_n - x^*)^3$$
$$+ \frac{F^{(4)}(x^*)}{4!}(x_n - x^*)^4 + \frac{F^{(5)}(x^*)}{5!}(x_n - x^*)^5 + \frac{F^{(6)}(x^*)}{6!}(x_n - x^*)^6 + O((x_n - x^*)^7). \tag{8}$$

Substituting (7) into (8) yields

$$x_{n+1} = x^* + e_{n+1} = x^* - \frac{3}{2}c_2(c_3 + 2{c_2}^2)(5c_3 - 6{c_2}^2)e_n^6 + O(e_n^7).$$

Therefore, we have

$$e_{n+1} = -\frac{3}{2}c_2(c_3 + 2{c_2}^2)(5c_3 - 6{c_2}^2)e_n^6 + O(e_n^7)$$

which shows that Algorithm 1 is sixth-order convergent.

To obtain an assessment of the efficiency of the proposed method, we shall make use of efficiency index, according to which the efficiency of an iterative method is given by $p^{1/\omega}$, where p is the order of the method and ω is the number of function evaluations per iteration required by the method. It is not hard to see that the efficiency index of Algorithm 1 is 1.565 which is better than that of the classical Newton's method 1.414.

3. Numerical Results

Now, we employ Algorithm 1 to solve some nonlinear equations and compare them with NM and the iterative method (PPM for short) Potra and Pták presented in [7]

$$x_{n+1} = x_n - \frac{f(x_n) + f(y_n)}{f'(x_n)} \tag{9}$$

which is cubically convergent with efficiency index 1.442, where $y_n = x_n - \frac{f(x_n)}{f'(x_n)}$.

Displayed in Table 1 are the number of iterations (ITs) required such that $|f(x_n)| < 1.E-14$.

Table 1. Comparison of Algorithm 1, PPM and NM

Functions	x_0	NM	PPM	Algorithm 1
f_1	1	5	3	3
	1.45	4	3	3
f_2	2.5	6	3	3
	1. 5	7	5	4
f_3	0.5	4	3	3
	3.15	7	4	3
f_4	4.1	16	8	6
	3.5	12	5	4
f_5	7.9	15	11	8
	-0.6	4	4	3
f_6	1.9	5	4	3
	2.1	5	4	4

In table 1, we use the following functions.

$f_1(x) = x^3 + 4x^2 - 10,\ \alpha = 1.36523001341410.$

$f_2(x) = (x-1)^3 - 1,\ \alpha = 2.$

$f_3(x) = \cos x - x,\ \alpha = 0.73908513321516.$

$f_4(x) = e^{x^2+7x-30} - 1,\ \alpha = 3.$

$f_5(x) = (x+2)e^x - 1,\ x^* = -0.44285440096708.$

$f_6(x) = \sin^2(x) - x^2 + 1,\ x^* = 1.40449164885154.$

The computational results in Table 1 show that Algorithm 1 requires less ITs than NM, and no more than PPM. Therefore, Algorithm is of practical interest and can compete with NM.

4. Conclusion

In order to obtain efficient iterative method for the nonlinear equations which come from the practical problems in the materials science and manufacturing technology field, in this paper, we present and analyze a modified sixth-order convergent Newton-type iterative method for solving nonlinear equations. The algorithm is free from second derivatives. Several numerical results illustrate the convergence behavior and computational efficiency of the method proposed in this paper. Computational results demonstrate that it is more efficient and performs better than the classical NM.

Keywords: AES; Key Expansion; Logistic; MATLAB

Abstract. AES (Advanced Encryption Standard) in May 26, 2002 became effective standard. AES algorithm research has become a hot topic at home and abroad, and the algorithm has been widely applied in the field of information security. Since the algorithm of AES key expansion part is open, so the key is between the wheel can be derived from each other, the AES algorithm designed for this security risk by generating pseudo-random number. Logistic mapping a certain length, after quantization is used as a key to improve the security of the AES algorithm.

Introduction

With the speeding up of the computer data processing, the DES encryption algorithm that has been public before due to its short packet length can be deciphered in the limited time and limited resources. So the DES encryption algorithm can no longer guarantee the security. AES encryption algorithm is now being widely used replacing DES. AES has 128-bit packet length which is variable. Make the data encryption get the final ciphertext and have higher security with the operation of ten rounds of replacement, substitution and the mixed key for each packet data during encryption. The initial key of AES is 128 bits, but AES algorithm needs 11 rounds of secret key which is 1408 bits key. So it needs to extend the original 128 bits key. Rijndael has put forward the key extension algorithm which is derived from the initial key, and the algorithm is public. So the attacker only needs to break one round keys that can deduce all keys. This brings hidden troubles to the security of the AES. This design idea is to produce 1408 bits of pseudo-random sequence as the key of AES algorithm which can ensure the key cannot be derived. The algorithm introduces the chaos model, comparing with the original algorithm it has higher security [1].

Chaos is a complex nonlinear process which can provide good pseudo random sequences. Chaotic system has high sensitivity to the initial parameters. Even though the initial value of two chaotic systems has minor differences, it can produce two sets of completely different and the discrete chaotic sequence values after a relatively short time. And the output of two systems can present a state of separation index after n iterations.

A new AES algorithm arises at the historic moment, integrating the advantages of chaotic systems and comparing with the traditional key extension of AES algorithm. The new AES algorithm is differ from the traditional algorithm, using a chaotic dynamical system to produce a pseudo random sequence as a key. That is to say, produce 1408 bits pseudo-random sequence as the encryption key. The characteristics of the modified AES encryption algorithm are as follows:

1. With higher algorithm security: The pseudo-random sequence produced by chaotic system has complexity and unpredictability. There is no rule to follow between each round of key sequence. Even if the interceptor calculates one round of the key, he cannot recover the plaintext owning to that he cannot calculate the previous round and after round of key. But the traditional key extension of AES algorithm is public. Once the interceptor calculates a round of key, he can calculate all keys [2]. Compared with the original algorithm, the modified key expansion algorithm has higher security.

2. With key sensitivity: Even though there is a slight initial deviation, corresponding positions changing rate of 0 and 1 in the two sequences obtained by experimental statistics is very large, due to the chaotic dynamical system with initial sensitivity. That is to say, the attack who speculates slight deviation cannot get the key sequence.

3. With a broader key space: Using the initial values x_n of chaotic dynamical systems as the encryption and decryption keys, the encryption machine can produce tens of thousands, hundreds of thousands or even more random sequences. Then we intercept 1408 bits from the sequences as the key. The key can be calculated using the method of powerful attacks when the development of computer processing speed is fast enough in the future, because that the traditional initial key for AES algorithm is only 128 bits [3]. Compared to the original algorithm speaking, AES algorithm improved provides a wider key space.

In summary, the improved AES algorithm with the sequences producing by chaotic dynamical systems as the encryption key overcome the security risk in the presence of key extension in the original algorithm. There are researching and realizing values.

Organization of the Text

A set of data in AES encryption processing requires eleven 128-bit keys in the original AES key expansion algorithm. But the initial key is only 128 bits, requiring to be expanded. AES key expansion algorithm is public, mainly including round key expansion and round key selecting two parts [4]. Make the 16 bytes of the initial key consist of 4-by-4 state matrix and each column of the matrix is a word. The four-word initial key w_0, w_1, w_2, w_3 need to be expanded the other words $w_4, w_5, w_6, w_7 ... w_{40}, w_{41}, w_{42}, w_{43}$. The expansion algorithm is $w_i \oplus w_{i+3} \rightarrow w_{i+4}$, where $i = 0,1...39$. First detect subscript $i+3$ of w_{i+3}, if $i+3$ is an integer multiple of 4, then make w_{i+3} function $H(x)$ substitution before $w_i \oplus w_{i+3}$ operation.

$H(x)$ is a four-byte input and output function, constituted by three sub-functions. The expansion function is main made up of the box S function (SubWord), the shift function (RotWord) and the XOR *RC* [5]. However, the problem has cropped up because key expansion is public. The key attacker who gets a round key will be able to calculate all keys based on the public expansion algorithm, which greatly reduces the security of encryption system [6].

The AES encryption requires 44 key words for encryption. In order to strengthen the security of encryption, this design takes advantage of Logistic mapping to generate a long enough pseudo-random sequence [7], from which intercept 1408 bits to quantization as the AES encryption key. The maximum feature of pseudo-random number is that the sequences cannot be deduced even knowing one or a sequence. It is also impossible to calculate its sequence value before and after. The pseudo-random number can effectively prevent attackers calculate the key. Without key attacker will not be able to recover the plaintext. Improved Algorithm AES flowchart is shown in Fig. 1:

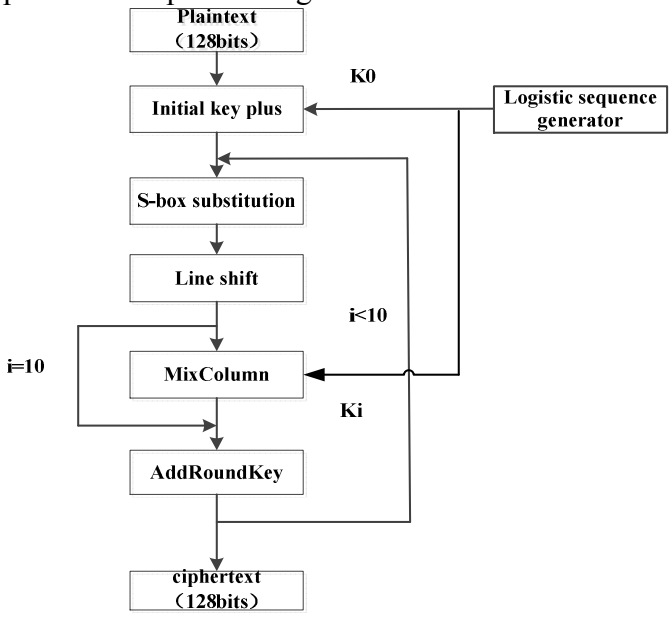

Fig. 1 The flowchart of improved AES data encryption algorithm

As shown in Fig. 1, all round keys of the improved AES encryption algorithm are generated by the Logistic module. And the algorithm enhances confidentiality performance by using the pseudo-random sequence which cannot be deduced.

Logistic model is defined as shown in Eq. 1:

$$x_{n+1} = \mu x_n (1 - x_n) . \ n = 1, 2, 3 ... \infty \quad (1)$$

When the initial conditions is $x_n \in [0,1]$, $\mu \in (0,4]$, the sequence $x_0, x_1, x_2 ... x_n$ generated by Logistic model is pseudo-random, non-convergence, sensitive to initial conditions, and the values of the sequence x_n are between 0 and 1. The design chooses $\mu = 3.58$, $x_0 = 0.75$. The values of the sequence $x_0, x_1, x_2 ... x_n$ generate by MATLAB simulation is 0.6713, 0.7900, 0.5939, 0.8634, 0.4221, 0.8733..., some of the workspace generated the sequence is shown in Fig. 2:

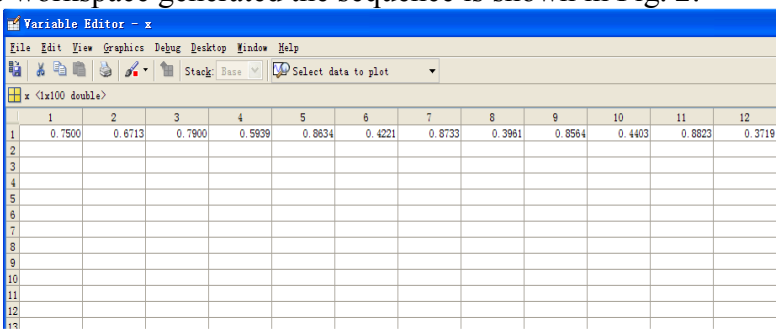

Fig. 2 Workspace of sequence x

Logistic sequence simulation shown in Fig. 3:

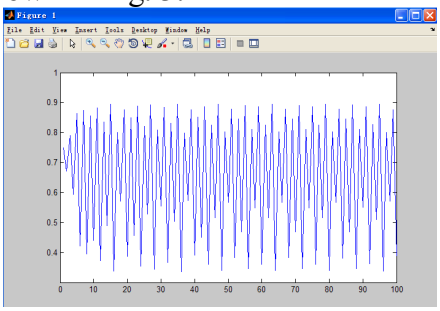

Fig. 3 Sequence of logistic mapping generated

As it shown in Fig. 3, the values of sequence between 0 and 1, and there is no cycle. Then we choose a fixed-point to simulate the Logistic map. This design uses 16-bit binary number to show fixed-point number. The position of the decimal point is between 14 and 15. And the range of it can be represented from 00.00000000000000 to 11.11111111111111.

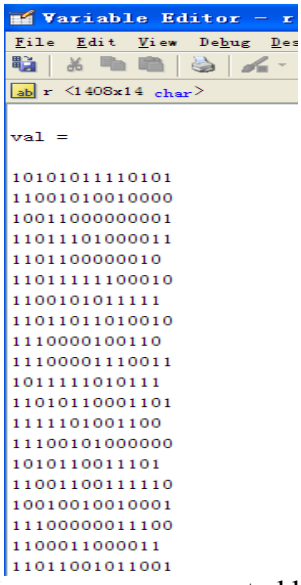

Fig. 4 The logistic sequences generated by the fixed-point

As shown in Fig. 4, the binary digits of sequence are more less than 14, due to the decimal point between the 14 and 15, so the value of the sequence is less than 1. Then we choose each 12-bit to quantify. The working space of the quantified sequence k is shown in Fig. 5:

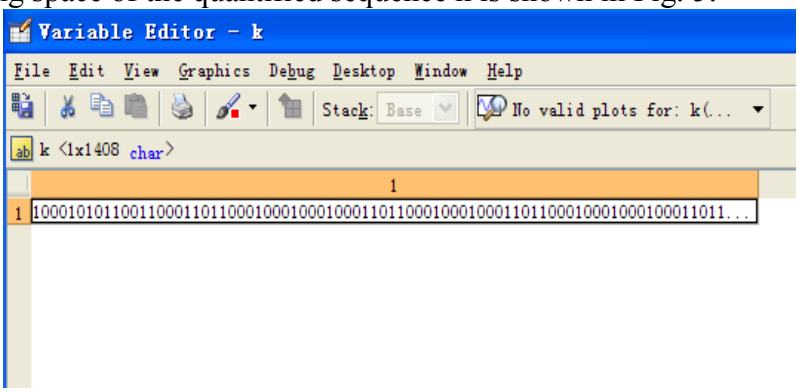

Fig. 5 The logistic sequence after quantify

As shown in Fig. 5, after quantization the k is 1048 bits, as modified for AES encryption algorithm.

Summary

In modern communication technology, information security technology requires more in-depth and widely applied to a variety of communication systems. This paper compares the advantages and disadvantages of packet encryption and stream encryption, and chooses encrypt packet encryption machine to design. Before the design, it introduces the number theory basic knowledge which is involved in AES, including the concept of group, ring, domain and algorithm in finite field. By using MATLAB to simulate the AES algorithm, it has verified the feasibility of AES algorithm. For the safe hidden trouble of AES algorithm between round keys which can be derived each other, the design uses the characteristics of chaotic sequence to improve AES algorithm. By using Logistic mapping to generate pseudo-random sequences, the design uses the pseudo-random sequence as the round keys of modified AES algorithm. Because the pseudo-random sequence is random in a certain period, so the relationship of sequences is not derived. After analysis concluding, that we use pseudo-random sequence as AES encryption key can enhance the security of the AES algorithm. And using MATLAB to simulate the modified AES algorithm can verify the feasibility of the new algorithm.

Keywords: Blind Equalization; CMA; Underwater Acoustic Channel; Quasi-newton Algorithm

Abstract. The CMA cost function is simplified to meet the second norm form, and a new CMA blind equalization based on quasi-newton algorithm is proposed. Since the CMA cost function does not meet the second norm form, it is difficult to use quasi-newton algorithm to update the blind equalizer directly based on the cost function of CMA. If the cost function is simplified to meet the second norm form, it can use quasi-newton algorithm to update the blind equalizer directly. Thus, the convergence rate and convergence precision of CMA blind equalization can be improved effectively. Simulation results under the acoustic channels show that CMA blind equalization with quasi-newton algorithm based on the simplified cost function has faster convergence rate and less steady state residual error, which has practical value in the blind equalization of fast time-varying underwater acoustic channels

Introduction

Adaptive blind equalization technology provides a powerful technical support to achieve high-quality and high-speed communication for the limited bandwidth underwater acoustic communication system. Adaptive blind equalization can compensate and track the communication channel by receiving signals without any training sequence to effectively save the communication bandwidth and prevent equalizer from locking. Blind equalization technology has potential application value in wireless communication, especially in underwater acoustic communication system [1]. CMA has received great attention for its simple and easy to achieve and CMA based on the gradient descent has the defects of low convergence rate and big steady state residual error after convergence. To overcome the defects of CMA blind equalization, many improved algorithms are proposed. Quasi-newton algorithm can make use of the second derivative of the cost function, which can speed up the convergence rate and improve the global convergence performance. But the cost function of CMA does not meet the second norm form, so it is difficult to deduce and use quasi-newton algorithm from theory. Therefore, the cost function of CMA is simplified to meet the second norm form in this paper, and the quasi-newton CMA is deduced and analyzed based on the simplified cost function. Computer simulation results show that, compared with CMA blind equalization, the CMA blind equalization with quasi-newton algorithm based on simplified cost function has better equalization performance in underwater acoustic communication system.

The Simplified CMA cost function

CMA is a special case of Bussgang blind equalization algorithms, which is well suited for sending signals having constant envelope. CMA algorithm sets parameter $p = 2$ in Godard algorithm. Fig.1 shows the baseband model of CMA blind equalization [2].

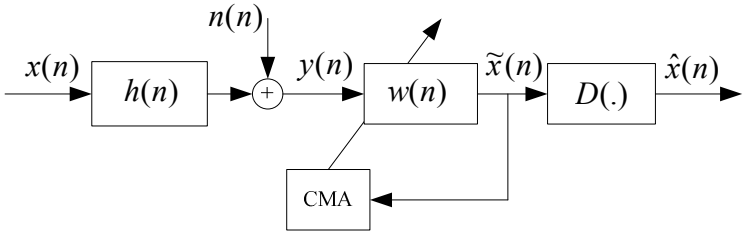

Fig.1 The principle of CMA

In Fig.1, $x(n)$ is the input sequence, $h(n)$ is the unknown channel impulse response, $n(n)$ is gauss white noise ,then the observed sequence $y(n)$ as the blind equalizer input sequence is received. The recovered signal $\hat{x}(n)$ can be obtained by the decision device $G(.)$ at the output signal $\tilde{x}(n)$. The CMA cost function is given by

$$J(n) = E\left[R_2 - \left|\tilde{x}(n)\right|^2 \right]^2 \tag{1}$$

According to signal transmission principle of the communication system, the $\tilde{x}(n)$ can be given by

$$\tilde{x}(n) = w^H(n) y(n) \tag{2}$$

then, the cost function of CMA can be given by

$$J(n) = [R_2 - w^H(n) y(n) (w^H(n) y(n))^*]^2 \tag{3}$$

where the symbol " H " is the complex conjugate transpose operator. If let

$$u(n) = y(n) (w(n)^H y(n))^* \tag{4}$$

then Eq.3 can be given by

$$J(n) = [R_2 - w^H(n) u(n)]^2 \tag{5}$$

Eq.5 satisfies the quadric standard form, but the expression $u(n)$ contains the variable $w(n)$, so $u(n)$ cannot be taken as the equivalent equalizer input variable. Hereby the approximate expression of $u(n)$ is given by

$$\tilde{u}(n) = y(n) (w^H(n-1) y(n))^* \tag{6}$$

if the algorithm is convergent, then there must be

$$\lim_{n\to\infty} \left\| w(n) - w(n-1) \right\| = 0 \tag{7}$$

So, it is rational to use $\tilde{u}(n)$ to approximate $u(n)$. The CMA cost function can be simplified to

$$J(n) = [R_2 - w^H(n) \tilde{u}(n)]^2 \tag{8}$$

The Quasi-Newton CMA Blind Equalization

The mean square error performance surface formed by the quadratic function of the weight coefficient vector of the adaptive transversal equalizer can be described by the mean square error [3], the mean square error can be given by

$$\xi(n+1) = R_2^2 - 2w^H(n+1) P + w^H(n+1) R w(n+1) \tag{9}$$

where R is the autocorrelation matrix of the equalizer input signal and P is the cross-correlation matrix of the input signal and the desired signal. Subtract $\xi(n+1)$ and $\xi(n)$ can obtain

$$\xi(n+1) = \xi(n) + \nabla^H(n) \left[w(n+1) - w(n) \right] + \left[w(n+1) - w(n) \right]^H R \left[w(n+1) - w(n) \right] \tag{10}$$

where $\nabla^H(n) = -2P + 2Rw(n)$ is the gradient vector of the mean square error. Similarly, $\xi(n)$ is the mean square error of the equalizer. If strive for the partial derivative, that is the momentary value $(n+1)$ of $\xi(n)$ and $w(n+1)$, then make it to zero, we have

$$w(n+1) = w(n) - \frac{1}{2} R^{-1} \nabla(n) \tag{11}$$

Eq.11 is the iterative formula of the newton algorithm. The optimal solution can be obtained after iteration based on the newton algorithm, that is

$$w(n+1) = R^{-1}P = w_{opt} \tag{12}$$

But in practical applications, the autocorrelation matrix R and the cross-correlation matrix P and the gradient vector $\nabla(n)$ cannot be all precisely known. According to the idea of LMS, we can substitute the estimate value for the actual value, and then the iterative formula of the quasi-newton algorithm can be given by

$$w(n+1) = w(n) - \mu\hat{R}^{-1}(n)\hat{\nabla}(n) \tag{13}$$

where $\hat{R}(n)$ and $\hat{\nabla}(n)$ are the instantaneous estimation of the autocorrelation matrix R and the gradient vector $\nabla(n)$ respectively, when the input signal satisfies the stationary random process, the unbiased estimation of the autocorrelation matrix R can be given by

$$\hat{R}(n) = \frac{1}{n+1}\sum_{i=0}^{n} y(i)y^T(i) = \frac{1}{n+1}\hat{R}(n-1) + \frac{1}{n+1}y(n)y^T(n) \tag{14}$$

From Eq.14, we can see the autocorrelation matrix $\hat{R}(n)$ can be obtained from recurrence. The mathematical expectation of $\hat{R}(n)$ can be given by

$$E[\hat{R}(n)] = \frac{1}{n+1}\sum_{i=0}^{n} E[y(i)y^T(i)] = R \tag{15}$$

Then Eq.15 is the unbiased estimation. The sliding exponential window estimation and the sliding rectangular window estimation are the estimation methods, which are frequently used in the estimation to the autocorrelation matrix R. where the recursion formula of the sliding exponential window estimation is

$$\hat{R}(n) = \lambda\hat{R}(n-1) + y(n)y^T(n) \tag{16}$$

where λ is the forgetting factor.

The computation complexity of iteration in the matrix inversion is $O(N^3)$. To avoid the computation of the matrix inversion, we can use the matrix inversion lemma formula to obtain the matrix inversion, that is

$$[A+BCD]^{-1} = A^{-1} - A^{-1}B[DA^{-1}B + C^{-1}]^{-1}DA^{-1} \tag{17}$$

where A and C is non-singular matrix. If $A = (1-\alpha)\hat{R}(n-1)$, $B = D^T = x(n)$, $C = \alpha$, the calculation formula of $R^{-1}(n)$ can be given by

$$\hat{R}^{-1}(n) = \frac{1}{1-\alpha}\left[\hat{R}^{-1}(n-1) - \frac{\hat{R}^{-1}(n-1)y(n)y^T(n)\hat{R}^{-1}(n-1)}{\frac{1-\alpha}{\alpha} + y^T(n)\hat{R}^{-1}(n-1)y(n)}\right] \tag{18}$$

According to Eq.18, we can make the recursion calculation to $R^{-1}(n)$. The computation complexity of every iteration calculation is $O(N^3)$, which is below the inverse matrix of the directing calculation of $\hat{R}(n)$.Estimate the gradient vector based on LMS, and then the equalizer weight efficient of the quasi-newton algorithm can be updated as follow

$$w(n+1) = w(n) + \mu e(n)\hat{R}^{-1}(n)\tilde{u}(n) \tag{19}$$

The inverse of the autocorrelation matrix can be initialized to

$$\hat{R}^{-1}(0) = \delta I \tag{20}$$

Simulations and Analysis

The simulation channel is adopted the two-ray sparse underwater acoustic channel [4], the transfer function of the channel is

$$H(z) = 1 + 0.59997z^{-20} \tag{21}$$

The sending signal is modulated by 4-QAM and $SNR = 25\,\mathrm{dB}$ .The length of transversal equalizer is 84, and the center taps is initialized to 1, step size $\mu = 0.002$. Fig.2 shows the convergence curve of ISI based on CMA（NG-CMA）and LMS-CMA .Where the computational method of ISI is given by [5]

$$ISI(n) = \frac{\sum_i |C_i(n)|^2 - |C_i(n)|^2_{\max}}{|C_i(n)|^2_{\max}} \tag{22}$$

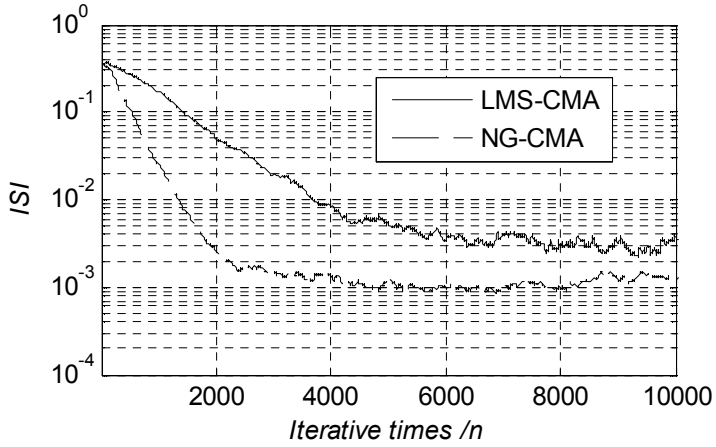

Fig.2 ISI convergence curve

Fig.2 shows that NG-CMA has the faster convergence rate and the smaller steady state residual ISI compared with LMS-CMA. It is demonstrated that NG-CMA has the validity of the equalization performance.

Conclusions

The quasi-newton CMA is deduced and analyzed based on the simplified cost function of CMA. The quasi-newton algorithm improves the convergence rate and the convergence precision effectively at the expense of a little computational complexity. NG-CMA proposed in this paper has the application value in the time-varying underwater acoustic channels.

Keywords: Complex frequency shifted, finite- difference time-domain, hybrid implicit-explicit, perfectly matched layer

Abstract. In this paper, an implementation of the complex-frequency-shifted perfectly matched layer (CPML) is developed for three-dimensional hybrid implicit-explicit (HIE) finite-difference time-domain (FDTD) method based on auxiliary differential equation (ADE). Because of the use of the ADE technique, this method becomes more straightforward and easier to implement. The formulations for the HIE-FDTD CPML are proposed. Numerical examples are given to verify the validity of the presented method. Results show that, both HIE-CPML and FDTD-CPML have almost the same reflection error, while their reflection error is about 30 dB, which is less than HIE Mur's first-order results. The contour plots indicate that the maximum relative reflection as low as -72 dB is achieved by selecting $\kappa_{\max} = 14$ and $\sigma_{\max}/\sigma_{opt} = 1.0$.

Introduction

The finite-difference time-domain (FDTD) method [1] has been proven to be an effective scheme for solving varieties of electromagnetic problems. However, it is an explicit algorithm, the time-step size is confined by the Courant-Friedrich-Levy (CFL) condition [2]. As a result, the maximum time-step is limited by the minimum cell size in a computational domain, which makes this method inefficient for the problems where fine-scale structures are involved.

To overcome the restriction of the CFL limit on the time step-size, unconditionally stable methods have been studied extensively, such as the alternating direction implicit (ADI) FDTD method [3] [4]. However, in the ADI-FDTD scheme, it must solve six tri-diagonal matrices and six explicit updates for one updating cycle, which makes the ADI-FDTD computationally inefficient.

To overcome the above drawback of the ADI-FDTD method, a hybrid implicit-explicit (HIE) FDTD method was proposed [5]-[7] namely HIE-FDTD method. For a lot of advantages, this method has been introduced to solve the body-of-revolution problems [8], as well as the periodic problems [9].

When open structures are involved, the absorbing boundary conditions (ABCs) are required to truncate the computational domain [2]. The complex frequency-shifted (CFS) perfectly matched layer (PML) is widely used for its easy implementation and high efficiency at absorbing low-frequency evanescent waves [10]-[13].

In this paper, an implementation of CFS-PML using auxiliary differential equation (ADE) for 3-D HIE-FDTD is developed. Numerical results are compared with the conventional FDTD-CPML and the Mur's first-order ABC results. The contour plots indicate that the maximum relative reflection as low as -72 dB is achieved by selecting $\kappa_{\max} = 14$ and $\sigma_{\max}/\sigma_{opt} = 1.0$. The formulations and numerical results are proposed in the following sections.

Mathematical Formulations

The PML technique consists in surrounding a computational domain with the absorbing layer. In the PML layer, the following equations replace the normalized Maxwell's equations [12]

$$j\omega\varepsilon E_i = S_j^{-1}\frac{\partial H_k}{\partial j} - S_k^{-1}\frac{\partial H_j}{\partial k} \tag{1a}$$

$$j\omega\mu H_i = S_k^{-1}\frac{\partial E_j}{\partial k} - S_j^{-1}\frac{\partial E_k}{\partial j} \tag{1b}$$

where ε,μ represent the permittivity and permeability, $i=x,y,z$, $j=y,z,x$, $k=z,x,y$, alternately. $S_\eta,(\eta=x,y,z)$ are called the stretched-coordinate variables. To achieve high efficiency of the wave absorbing, for the sake of generality, $S_\eta,(\eta=x,y,z)$ are chosen within the PML region as

$$S_\eta = \kappa_\eta + \sigma_\eta/(\alpha_\eta + j\omega\varepsilon) \tag{2a}$$

And then

$$S_\eta^{-1} = 1/\kappa_\eta + b_\eta/(j\omega + a_\eta) \tag{2b}$$

where $b_\eta = -\sigma_\eta/(\varepsilon\kappa_\eta^2)$, $a_\eta = (\alpha_\eta + \sigma_\eta/\kappa_\eta)/\varepsilon$. κ_η, σ_η and α_η are nonnegative real numbers. This choice for the metrics was originally proposed by Kuzuoglu and Mittra and is referred to here as the CFS-PML stretched coordinate metrics. For $\alpha_\eta > 0$, this choice has the advantage that it allows the PML to be highly absorptive of low-frequency waves [11]. Then the field components can be obtained in the similar way as it is in [12].

Without loss of generality, assume that the narrow side is along the y- direction. Following the HIE-FDTD scheme [6], [7], the electromagnetic fields are arranged on the cells in the same way as that used in the conventional Yee's staggered FDTD algorithm [1]. The E_y and H_y fields are defined at the time steps n-1/2 and n+1/2, the other fields at the time steps n and n+1. By discretizing the space and time derivatives, the field components can be obtained

$$\begin{aligned} &E_y^{n+1/2}\big|_{i,j+1/2,k} = \kappa_z^{-1}\big|_k \frac{\Delta t}{\varepsilon\Delta z}\left(H_x^{n}\big|_{i,j+1.2,k+1/2} - H_x^{n}\big|_{i,j+1.2,k-1/2}\right) + E_y^{n-1/2}\big|_{i,j+1/2,k} \\ &-\kappa_x^{-1}\big|_i \frac{\Delta t}{\varepsilon\Delta x}\left(H_z^{n}\big|_{i+1/2,j+1/2,k} - H_z^{n}\big|_{i-1/2,j+1/2,k}\right) + \frac{1}{2}\frac{\Delta t}{\varepsilon}\left(f_{Eyz}^{\,n+1/2} + f_{Eyz}^{\,n-1/2}\right) - \frac{1}{2}\frac{\Delta t}{\varepsilon}\left(f_{Eyx}^{\,n+1/2} + f_{Eyx}^{\,n-1/2}\right) \end{aligned} \tag{3a}$$

$$\begin{aligned} &H_y^{n+1/2}\big|_{i+1/2,j,k+1/2} = -\kappa_z^{-1}\big|_{k+1/2} \frac{\Delta t}{\mu\Delta z}\left(E_x^{n}\big|_{i+1/2,j,k+1} - E_x^{n}\big|_{i+1/2,j,k}\right) + H_y^{n-1/2}\big|_{i+1/2,j,k+1/2} \\ &+\kappa_x^{-1}\big|_{i+1/2} \frac{\Delta t}{\mu\Delta x}\left(E_z^{n}\big|_{i+1,j,k+1/2} - E_z^{n}\big|_{i,j,k+1/2}\right) - \frac{\Delta t}{2\mu}\left(f_{Hyz}^{\,n+1/2} + f_{Hyz}^{\,n-1/2}\right) + \frac{\Delta t}{2\mu}\left(f_{Hyx}^{\,n+1/2} + f_{Hyx}^{\,n-1/2}\right) \end{aligned} \tag{3b}$$

where Δt is the time-step size, Δx Δy and Δz are the cell sizes in the x-, y- and z-direction, respectively, other components can be obtained in the same way.

One can find in (3) none of them can be updated directly, because they all contain unknown components on both sides of the equations. In (3a) and (3b), $f_{Eyz}^{\,n+1/2}$, $f_{Eyx}^{\,n+1/2}$, $f_{Hyx}^{\,n+1/2}$, $f_{Hyz}^{\,n+1/2}$ are unknown, they need to be calculated first, after that, E_y and H_y can be updated directly. Updating of E_x^{n+1} component needs the unknown H_z^{n+1} component at the same time, so the E_x^{n+1} component has to be updated implicitly. Updating of E_z^{n+1} component needs the unknown H_x^{n+1} component at the same time. After E_x^{n+1} and E_z^{n+1} components are obtained, H_x^{n+1} and H_z^{n+1} are explicitly updated straightforwardly.

From the equations derived above, it can be seen that the proposed scheme solves 2 tri-diagonal matrices, 4 explicit updates and 12 auxiliary variables in a full update running cycle. However, it needs to solve 6 tri-diagonal matrices, 6 explicit updates and 24 auxiliary variables in the ADI-FDTD method. So the computational resource can be saved in this proposed HIE-CPML method.

Numerical Results

In this section, numerical examples are proposed to validate the formulations of the CFS-PML for the 3D HIE-FDTD. The structure has 66×66×66 cells including 8 layers of CPML in each direction.

Point A at location (57, 33, 33) and point B at location (57, 57, 33) are the observation points. The sinusoidal modulated Gaussian pulse is used as a source at the center of the structure.

The cell size are $\Delta = \Delta x = \Delta y = \Delta z = 0.5\,\text{mm}$. For CPML the parameters are considered as [11]

$$\sigma(\rho) = \sigma_{\max}(\rho/d)^m \tag{5}$$

$$\kappa(\rho) = 1 + \kappa_{\max}(\rho/d)^m \tag{6}$$

where ρ indicates the distance from the air-PML interface into the PML layer, d is the depth of the PML, and m is the order of the polynomial and is chosen to be 4 in this example. In the cases presented, α is held constant through the PML.

For validation the HIE-CPML is compared with FDTD-CPML and the HIE Mur's first-order ABC results. Figure 1 shows the reflection error of the three methods observed at point A. The reflection error is calculated with the following formula:

$$20\log_{10}\left(\frac{\left|E_y^B(t) - E_y^S(t)\right|}{\max\left|E_y^B(t)\right|}\right) \tag{8}$$

where, $E_y^S(t)$ is the field value observed at a point in the simulation domain. $E_y^B(t)$ is obtained by extending dimensions of the simulation domain (to minimize the reflection effect from boundaries). Figure 1 demonstrates that both HIE-CPML and FDTD-CPML have almost the same reflection error, while their reflection error is about 30 dB less than HIE Mur's first-order results.

Next, it is instructive to observe the maximum reflection error as a function of the PML constructive parameters $\kappa_{\max}$, $\sigma_{\max}$ and α. To this end, Figure 2(a) and Figure 2(b) illustrate contour plots of the reflection error versus $\kappa_{\max}$ and $\sigma_{\max}$ with $\alpha = 0.003$ and $\alpha = 0.05$. It is demonstrated here that the maximum error with $\alpha = 0.003$ and $\alpha = 0.05$ are -72 dB. However, when $\alpha = 0.05$ the optimal error is realized over a much broader range of $\kappa_{\max}$ and $\sigma_{\max}$, making these values easier to predict. It can be seen that a maximum relative reflection as low as -72 dB is achieved by selecting $\kappa_{\max} = 14$ and $\sigma_{\max}/\sigma_{opt} = 1.0$.

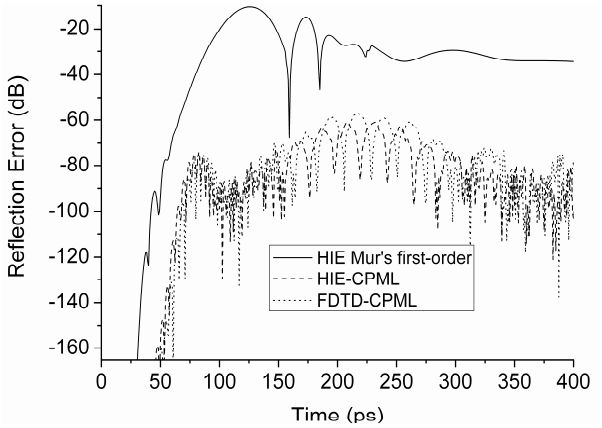

Figure 1. Reflection error of the HIE-CPML, FDTD-CPML and the HIE Mur's first-order results. ($\alpha = 0.003$, $\kappa_{\max} = 14$, $\sigma_{\max} = 0.7\sigma_{opt}$)

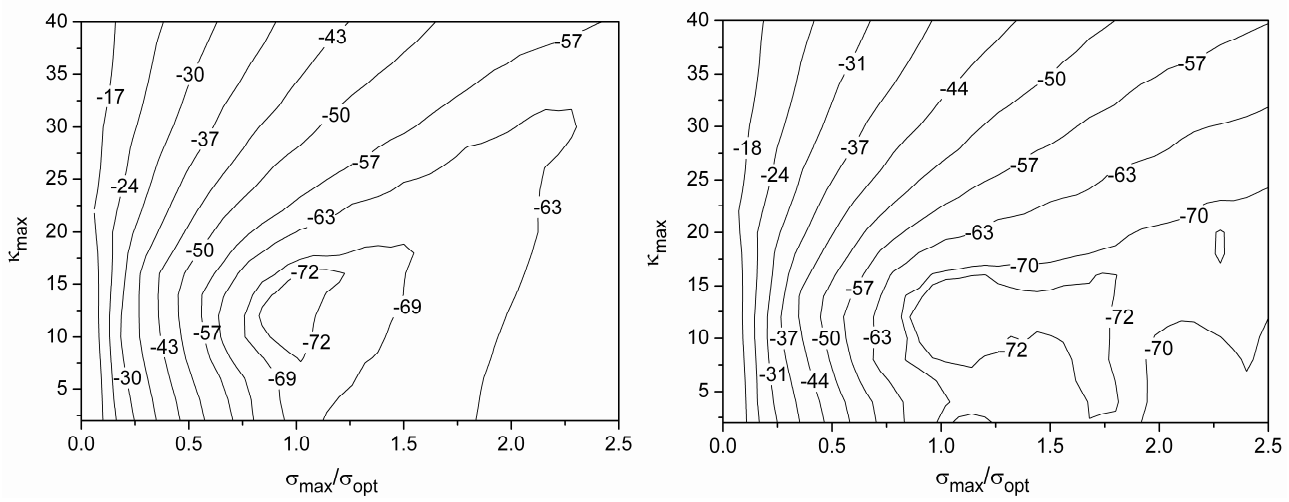
Conclusion

In this paper, the CFS-PML was developed for the three dimensional HIE-FDTD method. Formulations of the method are derived by using ADE technique. Numerical results show that this implementation is almost the same effective in reducing reflections of the conventional method. The maximum relative error is lower than -60 dB. The advantage of the HIE-CPML is its applicability at higher CFLN, as well as its accuracy. This development of CPML for the three dimensional HIE-FDTD method will enhance the application of the method.



(a) (b)

Figure 2. Maximum relative error at point A (57, 33, 33) as a function of $\kappa_{\max}$ and $\sigma_{\max}/\sigma_{opt}$ ($\alpha = 0.003$ and $m = 4$) and ($\alpha = 0.05$ and $m = 4$).

Keywords: Genetic Algorithms; Support Vector Machines; Optimization; Kernel Function

Abstract. In order to obtain more accurate parameters of support vector machine model, using genetic algorithm to optimize the parameters is an effective method. This paper analyzes the principle of support vector machine for regression, support vector machine kernel function selection, kernel parameters, penalty factor selection and adjustment methods, taking into account genetic algorithm is effective in solving optimization problems, proposed a method using genetic algorithm to optimize the parameters of support vector machine, which uses genetic algorithms to make cross-validation error minimized. The simulation results demonstrate the effectiveness of this method.

Introduction

Support vector machine (SVM) is a learning algorithm based on statistical learning theory proposed can solve the practical problems of small samples, nonlinearity, high dimension and local minima, with strong generalization ability. Practice shows that the type of kernel function, kernel parameters, and penalty factor is one of the key factors affecting the performance of the SVM, so research SVM parameter selection method for support vector machine development has a very important practical significance. This paper presents a global search capability using genetic algorithms to achieve the parameters of support vector machine optimization. The results showed that the genetic algorithm to optimize the parameters of SVM reduces the dependence on the initial value of the selected degrees. And with the traditional optimization algorithm is verified by comparing the genetic algorithm is used to support vector machine parameter optimization of validity and reliability.

Support vector regression principle

The basic idea SVR is to map the samples through a nonlinear mapping $\varphi(\cdot)$ from the original space $\boldsymbol{R^n}$ into a high dimensional feature space, and linear regression in feature space. For a given set of observations: $(\boldsymbol{x_i}, \boldsymbol{y_i}) \in \boldsymbol{R^n} \times \boldsymbol{R}, \boldsymbol{i} = 1,2,\cdots,\boldsymbol{N}$, optimal decision function can be constructed in a high -dimensional feature space:

$$\boldsymbol{y} = \boldsymbol{w} \cdot \varphi(\boldsymbol{x}) + \boldsymbol{b} \tag{1}$$

Where w and b are regression factors, which can be gained by minimizing the following regularized risk function

$$\boldsymbol{J} = \frac{1}{2}\|\boldsymbol{W}\|^2 + \boldsymbol{C} \cdot \boldsymbol{R}_{emp} \tag{2}$$

Among them, $\|\boldsymbol{W}\|$ control model complexity, C is the penalty factor to control the degree of experience in risk of punishment; $\boldsymbol{R}_{emp}$ is error control function, error control function commonly used linear ε loss function, quadratic loss function, select a different loss function can be constructed in different forms of support vector machines. In the text, select the quadratic loss function as the error control function, based on structural risk minimization principle, the above regression problem can be expressed as following optimization problem to solve:

$$\min \boldsymbol{J}(\boldsymbol{w},\xi)=\frac{1}{2}\|\boldsymbol{W}\|^2+\boldsymbol{C}\sum_{i=1}^{n}\xi^2 \tag{3}$$

$$\boldsymbol{s.t.}\ \boldsymbol{y}_i-\boldsymbol{w}\cdot\varphi(\boldsymbol{x}_i)-\boldsymbol{b}=\xi_i \qquad \text{i=1,2,}\cdots\text{,N}$$

Using Lagrange method, the above optimization problem can be transformed to its dual problem to solve, $\boldsymbol{w}$ can be given by:

$$\boldsymbol{w}=\sum_{i=1}^{n}\lambda_i\varphi(\boldsymbol{x}_i) \tag{4}$$

where λ_i is the Lagrange multiplier, $\boldsymbol{f}(\boldsymbol{x})$ can be given by:

$$\boldsymbol{f}(\boldsymbol{x})=\sum_{i=1}^{N}\lambda_i\varphi(\boldsymbol{x})\cdot\varphi(\boldsymbol{x}_i)+\boldsymbol{b}=\sum_{i=1}^{N}\lambda_i\boldsymbol{K}(\boldsymbol{x},\boldsymbol{x}_i)+\boldsymbol{b} \tag{5}$$

Among them, $\boldsymbol{K}(\boldsymbol{x},\boldsymbol{x}_i)=\varphi(\boldsymbol{x})\cdot\varphi(\boldsymbol{x}_i)$, $\boldsymbol{K}(\boldsymbol{x},\boldsymbol{x}_i)$ is the kernel function, which expressed from a low-dimensional space is mapped to some high-dimensional space. The kernel function is symmetric positive real number function while satisfying the conditions of Mercer plot.

SVM model parameter selection based on Genetic algorithm

In support vector regression estimation algorithm, the type of kernel function, kernel function parameters and the penalty factor are important parameters. Penalty factor C for balance training error and model complexity, Kernel function determines the input space to feature space mapping, commonly used kernel functions are:

① Polynomial kernel function

$$\boldsymbol{K}(\boldsymbol{x},\boldsymbol{x}_i)=(\boldsymbol{x}\cdot\boldsymbol{x}_i+\theta)^{\boldsymbol{d}} \tag{6}$$

② Radial basis kernel function

$$\boldsymbol{K}(\boldsymbol{x},\boldsymbol{x}_i)=\exp(-\frac{\|\boldsymbol{x}-\boldsymbol{x}_i\|}{\delta^2}) \tag{7}$$

③Sigmoid kernel function

$$\boldsymbol{K}(\boldsymbol{x},\boldsymbol{x}_i)=\tanh[\boldsymbol{u}(\boldsymbol{x}\cdot\boldsymbol{x}_i)-\boldsymbol{r}] \tag{8}$$

Choose different forms of kernel functions, we can generate different SVM, RBF kernel function is the most widely used kernel function, both in low or high dimensional space , for small samples or large samples, RBF kernel function are applicable, and has a wide domain of convergence, is an ideal kernel function. This paper selects RBF kernel function.

After a given training set and selected kernel function parameters that affect the performance of SVM main penalty factor and nuclear parameters. Support vector regression parameter optimization refers to selecting the optimal penalty factor C and kernel function parameter δ, so that SVM has the best prediction accuracy, and can improve the generalization ability of SVR. In order to obtain better generalization ability, it is necessary to adjust and optimize these parameters.

SVM parameter selection process is an optimized combination of parameters {C, δ} process, each point of the search space is a potential solution best model, and can be assessed by the generalization ability. Therefore, the process of solving the optimal parameters is essentially the process of generalization error is minimized. This paper uses K-fold cross-validation method to estimate the generalization error, K-fold cross-validation method: the training set is randomly divided into K disjoint subsets, Each subset of the same size, equal to L. A sub- set of taking them as a test set, the remaining K-1 subsets as the training set for a given set of parameters regression model, and calculate the mean square error of the test set，mean square error is given by the following formula:

$$\boldsymbol{MSE}(\boldsymbol{i})=\sqrt{\frac{1}{\boldsymbol{l}}\sum_{j=1}^{l}(\boldsymbol{y}_j-\hat{\boldsymbol{y}}_j)^2} \tag{9}$$

Where v denotes the mean square error of the i-th set. After the K iterations, the average value of mean square error as a desired generalization error, The average value of mean square error after k iterations as expected generalization error, Generalization error estimation can be expressed as:

$$T = \frac{1}{k}\sum_{i=1}^{k} MSE(i) \tag{10}$$

Where K generally selected 5 or 10. Select a set of parameters to achieve optimal generalization error minimization. In order to select the optimal set of parameters. Using cross-validation method to adjust the model parameters to achieve generalization error is minimized.

Genetic algorithm is a heuristic optimization algorithms proposed by Professor Holland, which is starting from any initial population, by random selection, crossover and mutation , producing a group of individuals more suitable environment to enable groups evolved to be getting better search space area , so multiply constantly evolve from generation to generation , and finally converge to a group of individual the most suitable environmental and obtain the optimal solution of the problem. Genetic algorithm is links with the problem to be solved only encoding and decoding, so it is widely used to solve complex optimization model. In order to obtain better SVM model, Specific implementation steps for using genetic algorithms to optimize C and δ parameters are as follows :

Step 1: Read the training samples, a set of random {C, δ} as an initial value, and the encoding structure of the initial population;

Step 2: The entire sample evenly divided into K mutually exclusive subsets S1, S2, ..., Sk;

Step 3: According to the current {C, δ} trained SVM, and calculate K-fold cross-validation error;

① Initialization i = 1; Si subset of the test set aside, and the rest of it as a subset of the training set, training SVM; calculation generalization error of the i-subset;

② I = i +1, repeat the above steps until i = k +1, calculate the average generalization error of k times, and get the K-fold cross-validation error, namely the generalization error;

Step 4: Select the generalization error T for the fitness function, and then using genetic algorithms to search better {C, δ};

Step 5: Apply selection, crossover and mutation operators to generate new populations , then repeat steps 2-4 until you meet the maximum number of iterations;

Step 6: Output optimal parameters, and through train SVM training samples to get the best regression model.

Simulation examples

Take a function sin c: $f(x) = \sin c(x) + v, x \in [-3,3]$, Where v is normally distributed with mean 0 and variance Gaussian noise 0.1. In the input variable domain to take 200 randomly generated sets of data , which were selected 100,80 and 50 groups of training and testing samples for simulation calculations, the goal is to minimize 5-fold cross-validation error, the kernel function is radial basis function. Using genetic algorithms optimize parameters δ and C, Where δ and C respectively initialized [0, 1] and [1,100] within, Genetic algorithm of the control parameters: population size is 40, evolution terations is 100, crossover probability is 0.5 and mutation probability is 0.005.

While Parameter optimization process, generalization error trends shown in Fig.1, Fig.2 shows using the parameters obtained by genetic algorithm to train SVM training sample, showing good results fitting. For ease of comparison, using orthogonal method and genetic algorithm multiple times, and the results of statistical residual mean square fit, and the results are shown in Tab.1.

Conclusion

Support vector machines based on structural risk minimization principle to overcome the neural network into local minima, does not converge, instability and other defects, make full use of the limited sample of information to get the optimal solution, and in learning and pan seek the best compromise between aging properties, the ability to get a good promotion.

Using support vector machine to predict, to select parameters is important, if the parameter is selected unreasonable, it may result in the calculation of under- and over- learning phenomena, which directly affect the prediction accuracy. The use of genetic algorithms automatically select SVM parameters so greatly improved predictive ability of the model, in order to improve the accuracy of the selected parameters, while optimizing the parameters in the text using a cross-validation method, the parameters set of best generalization ability as the final parameters. Ultimately resulting model is validated, get good prediction accuracy.

Keywords: BAM neural network; Markovian parameter; Robust stability; Time delay;

Abstract. The problem of robustly globally exponential stability in the mean square is investigated for stochastic uncertain discrete-time bidirectional associative memory (BAM) neural networks with time-varying delays and Markovian jumping parameters. The uncertainties are assumed to be the linear fractional form. By using Lyapunov-Krasovskii functional (LKF) method and some novel technique, a delay-dependent exponential stability criterion is established in terms of linear matrix inequalities (LMIs). A numerical example is provided to show the effectiveness and the improvement of the proposed methods.

Introduction

Neural networks have received considerable attention and successfully applied in many areas such as combinatorial optimization, signal processing and pattern recognition[1]. On the other hand, time delays are unavoidably encountered due to the finite speeds of the switching and transmission of signals in a network and may cause undesirable dynamic network behaviors such as oscillation and instability[2-4]. It has been shown in[5] that jumping between different neural work modes can be governed by a Markovian chain. As an extension of the unidirectional autoassociator of Hopfield, BAM neural network model was first introduced by [6], which generalizes the single-layer auto-associative Hebbian correlator to a two-layer pattern-matched hetero-associative circuit. Recently, the stability analysis for BAM neural networks has received much attention[7-10]. It is worth mentioning that most of references dealt with the continuous time case. However, in numerical simulations and practical implementations continuous-time neural networks, discretization is necessary and the dynamics of discrete-time neural networks may be quite different from those of continuous time ones. In the past few years, there has been rapidly growing interest in the problem of analysis for discrete-time neural networks with delays [11-15]. However, Markovian jumping parameters, stochastic external fluctuations and uncertainties were not addressed in the above references. To the best of our knowledge, few results have been reported in the literature concerning the problem of robust stability for stochastic uncertain discrete-time BAM neural networks with Markovian jumping parameters and time-varying delays, which remains important and challenging.

Motivated by the above reasons, the aim of this work is to deal with robustly exponential stability analysis for discrete-time Markovian jumping BAM neural network with uncertainties and stochastic fluctuations. The uncertainties under consideration are linear fractional form which includes the norm bounded uncertainties as a special case. The activation functions are considered the generalized type, which more general than the usual sigmoid functions and Lipschitz conditions. A new delay-dependent stability criterion is established by utilizing a modified LKF and some new methods. As a result, the conditions are expressed in the form of LMIs. A numerical example is given to illustrate the effectiveness of the proposed techniques.

Problem Statement and Preliminaries

For brief of analysis, we denote

$A_i = A(r_k), B_i = B(r_k), C_i = C(r_k), D_i = D(r_k), \Delta A_i = \Delta A(k, r_k), \Delta B_i = \Delta B(k, r_k), \Delta C_i = \Delta C(k, r_k),$

$\Delta D_i = \Delta D(k, r_k), \delta_1(k) = \delta_1(x(k), y(k-h(k)), k), \delta_2(k) = \delta_2(y(k), x(k-d(k)), k),$

$L_1 = \mathrm{diag}\left\{(l_1^+ + l_1^-)/2, (l_2^+ + l_2^-)/2, \cdots, (l_n^+ + l_n^-)/2\right\}, L_2 = \mathrm{diag}\{l_1^+ l_1^-, l_2^+ l_2^-, \cdots, l_n^+ l_n^-\},$

$K_1 = \mathrm{diag}\left\{(k_1^+ + k_1^-)/2, (k_2^+ + k_2^-)/2, \cdots, (k_n^+ + k_n^-)/2\right\}, K_2 = \mathrm{diag}\{k_1^+ k_1^-, k_2^+ k_2^-, \cdots, k_n^+ k_n^-\},$

$\overline{P}_{1i} = \sum_{j=1}^{s} \pi_{ij} P_{1j}, \overline{P}_{2i} = \sum_{j=1}^{s} \pi_{ij} P_{2j}, \overline{x}(k) = \sum_{l=k-d_M+1}^{k-d_m} x(l), \overline{y}(k) = \sum_{l=k-h_M+1}^{k-h_m} y(l), \hat{x}(k) = \sum_{l=k-d_M}^{k-1} x(l),$

$\hat{y}(k) = \sum_{l=k-h_M}^{k-1} y(l), \overline{g}(x(k)) = \sum_{l=k-d_M+1}^{k-d_m} g(x(l)), \overline{f}(y(k)) = \sum_{l=k-h_M+1}^{k-h_m} f(y(l)),$

$\zeta(k) = x(k+1) - x(k), \zeta(k) = y(k+1) - y(k).$

Let $(r_k, k \geq 0)$ be a Markov chain which takes values in the finite space $S = \{1, 2, \cdots, s\}$ with probability transition matrix:

$$\Pr\{r_{k+1} = j \mid r_k = i\} = \pi_{ij}, i, j \in S. \tag{1}$$

where π_{ij} is transition rate from mode i to mode j satisfying $\pi_{ij} \geq 0$ and $\sum_{j=1}^{s} \pi_{ij} = 1.$

Consider the Markovian jumping BAM neural network with uncertainties and stochastic fluctuations as follows:

$$\begin{cases} x(k+1) = -(A_i + \Delta A_i)x(k) + (B_i + \Delta B_i) f(y(k-h(k))) + \delta_1(k)\omega_1(k), \\ y(k+1) = -(C_i + \Delta C_i) y(k) + (D_i + \Delta D_i) g(x(k-d(k))) + \delta_2(k)\omega_2(k), \end{cases} \tag{2}$$

where $d_m \leq d(k) \leq d_M, h_m \leq h(k) \leq h_M$, A_i, B_i, C_i and D_i for any $i \in S$ are known constant matrices of appropriate dimensions, $\Delta A_i, \Delta B_i, \Delta C_i, \Delta D_i$ for any $i \in S$ that represent the linear fractional uncertainties, which are defined as

$$[\Delta A_i, \Delta B_i, \Delta C_i, \Delta D_i] = E_i[I - F_i(k)G_i]^{-1} F_i(k)[H_{1i}, H_{2i}, H_{3i}, H_{4i}], \tag{3}$$

where $E_i, G_i, H_{li}, (l = 1, \cdots, 4, i \in S)$ are known constant matrices and $G_i^{\mathrm{T}} G_i < I$; $F_i(k)$ is unknown real time-varying matrix with Lebesgue measurable elements bounded by $F_i^{\mathrm{T}}(k) F_i(k) \leq I.$ And $\omega_l(k)$ (l=1,2) are n-dimensional Brownian Motion on $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t \geq 0}, \mathcal{P})$, $\delta_1(k)$ and $\delta_2(k)$ satisfy **A1**: There exist matrices $X_j \geq 0, j = 1, 2, 3, 4$, such that

$$\begin{aligned} \delta_1^{\mathrm{T}}(k)\delta_1(k) &\leq x^{\mathrm{T}}(k) X_1 x(k) + y^{\mathrm{T}}(k-h(k)) X_2 y((k-h(k)), \\ \delta_2^{\mathrm{T}}(k)\delta_2(k) &\leq y^{\mathrm{T}}(k) X_3 y(k) + x^{\mathrm{T}}(k-d(k)) X_4 x(k-d(k)). \end{aligned} \tag{4}$$

The transformed neuron activation functions satisfy **A2**:

$$\begin{aligned} &[x^{\mathrm{T}}(k-d(k)) g^{\mathrm{T}}(x(k-d(k)))] \overline{\Upsilon}_1 [x^{\mathrm{T}}(k-d(k)) g^{\mathrm{T}}(x(k-d(k)))]^{\mathrm{T}} \geq 0, \\ &[y^{\mathrm{T}}(k-h(k)) f^{\mathrm{T}}(y(k-h(k)))] \overline{\Gamma}_1 [y^{\mathrm{T}}(k-h(k)) f^{\mathrm{T}}(y(k-h(k)))]^{\mathrm{T}} \geq 0, \\ &[x^{\mathrm{T}}(k) g^{\mathrm{T}}(x(k))] \overline{\Upsilon}_2 [x^{\mathrm{T}}(k) g^{\mathrm{T}}(x(k))]^{\mathrm{T}} \geq 0, [y^{\mathrm{T}}(k) f^{\mathrm{T}}(y(k))] \overline{\Gamma}_2 [x^{\mathrm{T}}(k) g^{\mathrm{T}}(x(k))]^{\mathrm{T}} \geq 0. \end{aligned} \tag{5}$$

where $\overline{\Upsilon}_k$, $\overline{\Gamma}_k, k = 1, 2$ are given in Theorem in this work.

The system in (2) or (6) is said to be robustly exponentially mean square stable if there exist positive scalars $\mu_0 > 1, \kappa_1 > 1, \kappa_2 > 1$ and integer $N > 1$,such that

$$\mathbb{E}\{\| x(N) \|^2 + \| y(N) \|^2\} \leq (\mu_0)^{-N} \left[\kappa_1 \max_{-d_M \leq l \leq 0} \| x(l) \|^2 + \kappa_2 \max_{-h_M \leq l \leq 0} \| y(l) \|^2 \right].$$

System (2) with uncertainties (3) can be further represented as follows:

$$\begin{cases} x(k+1) = -A_i x(k) + B_i f(y(k-h(k))) + \delta_1(k)\omega_1(k) + E_i\alpha_{1i}(k), \\ y(k+1) = -C_i y(k) + D_i g(x(k-d(k))) + \delta_2(k)\omega_2(k) + E_i\alpha_{2i}(k), \\ \alpha_{1i}(k) = F_i(k)\beta_{1i}(k), \\ \alpha_{2i}(k) = F_i(k)\beta_{2i}(k), \\ \beta_{1i}(k) = -H_{1i}x(k) + H_{2i}f(y(k-h(k))) + G_i\alpha_{1i}(k), \\ \beta_{2i}(k) = -H_{3i}y(k) + H_{4i}g(x(k-d(k))) + G_i\alpha_{2i}(k). \end{cases} \tag{6}$$

Main Results

Theorem: Suppose that **A1** and **A2** hold. Then, for given integers $h_M \geq h_m \geq 1, d_M \geq d_m \geq 1$, system (2) is globally robustly exponential stability in the mean square, if there exist some scalars $\tau_1 > 0, \tau_2 > 0$, some matrices $\Gamma_k = \mathrm{diag}\{\gamma_{k1}, \gamma_{k2}, \cdots, \gamma_{kn}\} > 0, \Upsilon_k = \mathrm{diag}\{\upsilon_{k1}\upsilon_{k2}, \cdots, \upsilon_{kn}\} > 0, P_{ki} > 0, Y_{ki} \geq 0,$ $Z_k > 0, i \in S, k = 1,2,$ $Q_l > 0, R_l > 0, l = 1,2,3,4$ with appropriate dimensions and matrices $N_l, l = 1,2,3,4$ with appropriate dimensions satisfying:

$$\begin{bmatrix} \Phi_{1i} + \Phi_{2i} + \Phi_3 + \Phi_3^{\mathrm{T}} & \sqrt{d_M - d_m}N_1 & \sqrt{d_M - d_m}N_2 & \sqrt{d_M}N_5 \\ \sqrt{d_M - d_m}N_1^{\mathrm{T}} & Q_1 - Q_2 & 0 & 0 \\ \sqrt{d_M - d_m}N_2^{\mathrm{T}} & 0 & R_1 - R_2 & 0 \\ \sqrt{d_M}N_5^{\mathrm{T}} & 0 & 0 & -Z_1 \end{bmatrix} < 0, \tag{7}$$

$$\begin{bmatrix} \Xi_{1i} + \Xi_{2i} + \Xi_3 + \Xi_3^{\mathrm{T}} & \sqrt{h_M - h_m}N_3 & \sqrt{h_M - h_m}N_4 & \sqrt{h_M}N_6 \\ \sqrt{h_M - h_m}N_3^{\mathrm{T}} & Q_3 - Q_4 & 0 & 0 \\ \sqrt{h_M - h_m}N_4^{\mathrm{T}} & 0 & R_3 - R_4 & 0 \\ \sqrt{h_M}N_6^{\mathrm{T}} & 0 & 0 & -Z_2 \end{bmatrix} < 0, \tag{8}$$

$$\overline{P}_{1i} < \tau_1 I,\ \overline{P}_{2i} < \tau_2 I, \tag{9}$$

where

$\Phi_{1i} = \mathrm{diag}\{Q_1 + (d_M - d_m)Q_2 - P_{1i} + \tau_1 X_1 + d_M Z_1, \tau_1 X_2 - Q_3, R_1 + (d_M - d_m)R_2, -R_3, 0, 0, 0, -Y_{1i}\},$

$\Xi_{1i} = \mathrm{diag}\{Q_3 + (h_M - h_m)Q_4 - P_{2i} + \tau_2 X_3 + h_M Z_2, \tau_2 X_4 - Q_1, R_3 + (h_M - h_m)R_4, -R_1, 0, 0, 0, -Y_{2i}\},$

$\Phi_{2i} = \mathcal{A}_{1i}^{\mathrm{T}}\overline{P}_{1i}\mathcal{A}_{1i} + \mathcal{H}_{1i}^{\mathrm{T}}Y_{1i}\mathcal{H}_{1i} + \mathcal{I}_1^{\mathrm{T}}\overline{\Gamma}_1\mathcal{I}_1 + \mathcal{I}_2^{\mathrm{T}}\overline{\Upsilon}_2\mathcal{I}_2, \mathcal{A}_{1i} = [-A_i\ 0\ 0\ B_i 0\ 0\ 0\ E_i],$

$\Xi_{2i} = \mathcal{A}_{2i}^{\mathrm{T}}\overline{P}_{2i}\mathcal{A}_{2i} + \mathcal{H}_{2i}^{\mathrm{T}}Y_{2i}\mathcal{H}_{2i} + \mathcal{I}_1^{\mathrm{T}}\overline{\Upsilon}_1\mathcal{I}_1 + \mathcal{I}_2^{\mathrm{T}}\overline{\Gamma}_2\mathcal{I}_2, \mathcal{A}_{2i} = [-C_i 0\ 0\ D_i\ 0\ 0\ 0\ E_i],$

$\Phi_3 = N_1 e_5 + N_2 e_6 + N_5 e_7, \Xi_3 = N_3 e_5 + N_4 e_6 + N_6 e_7, \mathcal{H}_{1i} = [-H_{1i}\ 0\ 0\ H_{2i}\ 0\ 0\ 0\ G_i], \mathcal{H}_{2i} = [-H_{3i} 0\ 0\ H_{4i}\ 0\ 0\ 0\ G_i],$

$$\overline{\Upsilon}_1 = \begin{bmatrix} -\Upsilon_1 L_2 & \Upsilon_1 L_1 \\ \Upsilon_1 L_1 & -\Upsilon_1 \end{bmatrix}, \overline{\Upsilon}_2 = \begin{bmatrix} -\Upsilon_2 L_2 & \Upsilon_2 L_1 \\ \Upsilon_2 L_1 & -\Upsilon_2 \end{bmatrix}, \overline{\Gamma}_1 = \begin{bmatrix} -\Gamma_1 K_2 & \Gamma_1 K_1 \\ \Gamma_1 K_1 & -\Gamma_1 \end{bmatrix}, \overline{\Gamma}_2 = \begin{bmatrix} -\Gamma_2 K_2 & \Gamma_2 K_1 \\ \Gamma_2 K_1 & -\Gamma_2 \end{bmatrix},$$

$\mathcal{I}_1 = \begin{bmatrix} e_2^{\mathrm{T}} & e_4^{\mathrm{T}} \end{bmatrix}, \mathcal{I}_2^{\mathrm{T}} = \begin{bmatrix} e_1^{\mathrm{T}} e_3^{\mathrm{T}} \end{bmatrix}, e_k = [0\ 0 \cdots 0\ \underset{k\text{th block}}{I}\ 0 \cdots o], k = 1,2,\cdots,8.$

Proof: For positive definite matrices $P_{ki} > 0, k = 1,2, Q_j > 0, R_j > 0, j = 1,2,3,4$, let us consider the LKF candidate:

$$V(k) = V_1(k) + V_2(k) + V_3(k) + V_4(k) + V_5(k) + V_6(k), \tag{10}$$

where

$$V_1(k) = x^{\mathrm{T}}(k)P_{1i}x(k) + y^{\mathrm{T}}(k)P_{2i}y(k), V_2(k) = \sum_{l=k-d(k)}^{k-1} x^{\mathrm{T}}(l)Q_1 x(l) + \sum_{l=-d_M+2}^{-d_m+1}\sum_{j=k+l-1}^{k-1} x^{\mathrm{T}}(j)Q_2 x(j),$$

$$V_3(k) = \sum_{l=k-h(k)}^{k-1} y^{\mathrm{T}}(l)Q_3 y(l) + \sum_{l=-h_M+2}^{-h_m+1}\sum_{j=k+l-1}^{k-1} y^{\mathrm{T}}(j)Q_4 y(j), V_4(k) = \sum_{l=k-d(k)}^{k-1} g^{\mathrm{T}}(x(l))R_1 g(x(l)) + \sum_{l=-d_M+2}^{-d_m+1}\sum_{j=k+l-1}^{k-1} g^{\mathrm{T}}(x(j))R_2 g(x(j)),$$

$$V_5(k) = \sum_{l=k-h(k)}^{k-1} f^{\mathrm{T}}(y(l))R_3 f(y(l)) + \sum_{l=-h_M+2}^{-h_m+1}\sum_{j=k+l-1}^{k-1} f^{\mathrm{T}}(y(j))R_4 f(y(j)), V_6(k) = \sum_{l=-d_M}^{-1}\sum_{j=k+l-1}^{k-1} x^{\mathrm{T}}(j)Z_1 x(j) + \sum_{l=-h_M}^{-1}\sum_{j=k+l-1}^{k-1} y^{\mathrm{T}}(j)Z_2 y(j).$$

Calculating the difference of $V(k)$ along the system (6), taking the mathematical expectation, and using the finite sum equality in [16],we have

$$\mathbb{E}\{\Delta V(k)\}=\sum_{l=1}^{6}\mathbb{E}\{\Delta V_l(k)\}=\sum_{l=1}^{6}\mathbb{E}\{V_l(k+1)-V_l(k)\} \tag{11}$$

where

$$\begin{aligned}
&\xi_1^{\mathrm{T}}(k)=[x^{\mathrm{T}}(k)\,y^{\mathrm{T}}(k-h(k))\,g^{\mathrm{T}}(x(k))\,f^{\mathrm{T}}(y(k-h(k)))\,\overline{x}^{\mathrm{T}}(k)\,\overline{g}^{\mathrm{T}}(k)\,\hat{x}^{\mathrm{T}}(k)\,\alpha_{1i}^{\mathrm{T}}(k)],\\
&\xi_2^{\mathrm{T}}(k)=[y^{\mathrm{T}}(k)\,x^{\mathrm{T}}(k-d(k))\,f^{\mathrm{T}}(y(k))\,g^{\mathrm{T}}(x(k-d(k)))\,\overline{y}^{\mathrm{T}}(k)\,\overline{f}^{\mathrm{T}}(k)\,\hat{y}^{\mathrm{T}}(k)\,\alpha_{2i}^{\mathrm{T}}(k)],\\
&\mathbb{E}\{\Delta V_1(k)\}=-x^{\mathrm{T}}(k)P_{1i}x(k)-y^{\mathrm{T}}(k)P_{2i}y(k)+\delta_1^{\mathrm{T}}(k)\overline{P}_{1i}\delta_1(k)+\delta_2^{\mathrm{T}}(k)\overline{P}_{2i}\delta_2(k)\\
&\quad+[-A_ix(k)+B_if(y(k-h(k))+E_i\alpha_{1i}(k)]^{\mathrm{T}}\times\overline{P}_{1i}[-A_ix(k)+B_if(y(k-h(k))+E_i\alpha_{1i}(k)]\\
&\quad+[-C_iy(k)+D_ig(x(k-h(k))+E_i\alpha_{2i}(k)]^{\mathrm{T}}\,\overline{P}_{2i}[-C_iy(k)+D_ig(x(k-d(k))+E_i\alpha_{2i}(k)],\\
&\mathbb{E}\{\Delta V_2(k)\}\le x^{\mathrm{T}}(k)[Q_1+(d_M-d_m)Q_2]x(k)-x^{\mathrm{T}}(k-d(k))Q_1x(k-d(k))\\
&\quad+(d_M-d_m)\xi_1^{\mathrm{T}}(k)N_1(Q_2-Q_1)^{-1}N_1^{\mathrm{T}}\xi_1(k)+2\xi_1^{\mathrm{T}}(t)N_1\overline{x}(k),\\
&\mathbb{E}\{\Delta V_3(k)\}\le y^{\mathrm{T}}(k)[Q_3+(h_M-h_m)Q_4]y(k)-y^{\mathrm{T}}(k-h(k))Q_3y(k-h(k))\\
&\quad+(h_M-h_m)\xi_2^{\mathrm{T}}(k)N_3(Q_4-Q_3)^{-1}N_3^{\mathrm{T}}\xi_2(k)+2\xi_2^{\mathrm{T}}(t)N_3\overline{y}(k),\\
&\mathbb{E}\{\Delta V_4(k)\}\le g^{\mathrm{T}}(x(k))[R_1+(d_M-d_m)R_2]g(x(k))-g^{\mathrm{T}}(x(k-d(k)))R_1g(x(k-d(k)))\\
&\quad+(d_M-d_m)\xi_1^{\mathrm{T}}(k)N_2(R_2-R_1)^{-1}N_2^{\mathrm{T}}\xi_1(k)+2\xi_1^{\mathrm{T}}(t)N_2\overline{g}(k),\\
&\mathbb{E}\{\Delta V_5(k)\}\le f^{\mathrm{T}}(y(k))[R_3+(h_M-h_m)R_4]f(y(k))-f^{\mathrm{T}}(y(k-h(k)))R_3f(y(k-h(k)))\\
&\quad-(h_M-h_m)\xi_2^{\mathrm{T}}(k)N_4(R_4-R_3)^{-1}N_4^{\mathrm{T}}\xi_2(k)+2\xi_2^{\mathrm{T}}(t)N_4\overline{f}(k),\\
&\mathbb{E}\{\Delta V_6(k)\}=d_Mx^{\mathrm{T}}(k)Z_1x(k)+h_My^{\mathrm{T}}(k)Z_2y(k)+d_M\xi_1^{\mathrm{T}}(k)N_5Z_1^{-1}N_5^{\mathrm{T}}\xi_1(k)+2\xi_1^{\mathrm{T}}(t)N_5\hat{x}(k)\\
&\quad+h_M\xi_2^{\mathrm{T}}(k)N_6Z_2^{-1}N_6^{\mathrm{T}}\xi_2(k)+2\xi_2^{\mathrm{T}}(t)N_6\hat{y}(k).
\end{aligned} \tag{12}$$

On the other hand, it follows from (4) and (6), there exist matrices $Y_{1i},Y_{2i}\ge 0$ such that

$$\begin{aligned}
&\delta_1^{\mathrm{T}}(k)\overline{P}_{1i}\delta_1(k)\le\tau_1[x^{\mathrm{T}}(k)X_1x(k)+y^{\mathrm{T}}(k-h(k))X_2y(k-h(k))],\\
&\delta_2^{\mathrm{T}}(k)\overline{P}_{2i}\delta_2(k)\le\tau_2[y^{\mathrm{T}}(k)X_3y(k)+x^{\mathrm{T}}(k-d(k))X_4x(k-d(k))],
\end{aligned} \tag{13}$$

$$\xi_1^{\mathrm{T}}(k)\mathcal{H}_{1i}^{\mathrm{T}}Y_{1i}\mathcal{H}_{1i}\xi_1(k)-\alpha_{1i}^{\mathrm{T}}(k)Y_{1i}\alpha_{1i}(k)\ge 0,\ \xi_2^{\mathrm{T}}(k)\mathcal{H}_{2i}^{\mathrm{T}}Y_{2i}\mathcal{H}_{2i}\xi_2(k)-\alpha_{2i}^{\mathrm{T}}(k)Y_{2i}\alpha_{2i}(k)\ge 0. \tag{14}$$

Substituting (13) into (12) , adding the terms on the left sides of (5) and (14) to (12) leads to

$$\mathbb{E}\{\Delta V(k)\}\le\xi_1^{\mathrm{T}}(k)\Phi\xi_1(k)+\xi_2^{\mathrm{T}}(k)\Xi\xi_2(k)$$

where

$$\begin{aligned}
&\Phi=\Phi_{1i}+\Phi_{2i}+\Phi_3+\Phi_3^{\mathrm{T}}+d_MN_5Z_1^{-1}N_5^{\mathrm{T}}+(d_M-d_m)[N_1(Q_2-Q_1)^{-1}N_1^{\mathrm{T}}+N_2(R_2-R_1)^{-1}N_2^{\mathrm{T}}],\\
&\Xi=\Xi_{1i}+\Xi_{2i}+\Xi_3+\Xi_3^{\mathrm{T}}+h_MN_6Z_2^{-1}N_6^{\mathrm{T}}+(h_M-h_m)[N_3(Q_4-Q_3)^{-1}N_3^{\mathrm{T}}+N_4(R_4-R_3)^{-1}N_4^{\mathrm{T}}].
\end{aligned}$$

According to Schur complements formula, $\Phi<0$ and $\Xi<0$ are equivalent to (7) and 8), respectively. And (7) and (8) imply $Q_2-Q_1>0,Z_1>0,R_2-R_1>0$ and $Q_4-Q_3>0,\ Z_2>0,$ $R_4-R_3>0$, which are equivalent to $\Omega_j<0(j=1,2,\cdots,6)$. One can conclude $\mathbb{E}\{\Delta V(k)\}<0$, if (7)-(9) are feasible. Now, defining a new function $W(k)=\mu^kV(k)$, it can be seen that for any positive integer $N\ge 1$, there exists a scalar $\mu_0>1$ such that

$$\mathbb{E}\{\|x(N)\|^2+\|y(N)\|^2\}\le\left(\frac{1}{\mu_0}\right)^N\left[\frac{\lambda_1}{\lambda_0}\max_{-d_M\le l\le 0}\|x(l)\|^2+\frac{\lambda_2}{\lambda_0}\max_{-h_M\le l\le 0}\|y(l)\|^2\right],$$

where

$$\begin{aligned}
&\lambda_1=\lambda_{\max}(P_{1i})+(1+d_M)[(\lambda_{\max}(R_1)+(1+d_M-d_m)\lambda_{\max}(R_2))\|L\|^2+\lambda_{\max}(Q_1)+(1+d_M)\lambda_{\max}(Z_1)+(1+d_M-d_m)\lambda_{\max}(Q_2)],\\
&\lambda_2=\lambda_{\max}(P_{2i})+(1+h_M)[(\lambda_{\max}(R_3)+(1+h_M-h_m)\lambda_{\max}(R_4))\|K\|^2+\lambda_{\max}(Q_3)+(1+h_M)\lambda_{\max}(Z_2)+(1+h_M-h_m)\lambda_{\max}(Q_4)],\\
&\lambda_0=\min\{\lambda_{\min}(P_{1i}),\lambda_{\min}(P_{2i})\},L=\mathrm{diag}\{l_1,l_2,\cdots,l_n\},l_q=\max\{|l_q^-|,|l_q^+|\},K=\mathrm{diag}\{k_1,k_2,\cdots,k_n\};k_q=\max\{|k_q^-|,|k_q^+|\},q=1,2,\cdots,n.
\end{aligned}$$

Recalling the Definition, we can conclude that BAM neural network (2) is globally robustly exponentially stable in the mean square sense. This completes the proof.

Illustrative example

Example Consider system (2) with the following matrices

$A=\begin{bmatrix}0.5 & 0\\ 0 & 0.6\end{bmatrix}$, $B=\begin{bmatrix}0 & 0.1\\ 0.1 & 0.06\end{bmatrix}$, $C=\begin{bmatrix}0.9 & 0\\ 0 & 0.8\end{bmatrix}$, $D=\begin{bmatrix}-0.1 & 0.1\\ 0 & 0.1\end{bmatrix}$, $\Delta A=\Delta B=\Delta C=\Delta D=0$

Let $d(k)=2+(-1)^k, h(k)=4+2(-1)^k$. It is reported in [18] that the stability criterion in [11] can not be applied to this example because of the constraints on the delay functions. To compared with methods proposed by [18], we assume $L_1=K_1=0$ and $L_2=K_2=-I$ .We can verify that the stability condition proposed by Theorem in [18] is not satisfied when set $l_{\min}=k_{\min}=l_{\max}=k_{\max}=2$ $r=1.2$. However, when $d_m=h_m=2, d_M=2, h_M=6$, according to Theorem in this work, we can find that system (2) is still exponentially stable, which shows that the criterion proposed in this paper is an improvement over the one in [11,17].

Conclusion

The problem of robustly exponentially stable in the mean square for uncertain stochastic BAM neural networks with Markovian jumping parameters and variable delays has been studied. A new stability criterion has been proposed by using LKF method and the novel bounding technique. As a result, the conditions have been established in term of LMIs. Finally, a numerical example has been given to illustrate the effectiveness and the improvement of our results.

Keywords: Correlation Coefficient Estimation; Subspace Decomposition; MUSIC Algorithm

Abstract. the correlation coefficient estimation algorithm based on subspace decomposition is presented in this paper. The correlation coefficient between the signals is obtained by getting eigen-value decomposition of the data covariance matrix, and deriving the relationship between signal subspace and noise subspace. Simulation results verify that this algorithm can be realized to get the correlation coefficient between two incident signals whose DOA are known and the effect of the correlation coefficient estimation is made by different signal direction angular intervals.

Introduction

Correlation coefficient of random variables has wide applications in statistical analysis.[1] In the field of signal processing, the correlation coefficient is used to indicate the degree of correlation between the signals. The conventional Algorithm of getting correlation coefficient applies only to know the source of the two signals, respectively, because the signal that array received is the result after the incident signal synthesis. so the conventional algorithm does not apply to the case of data that array receive. When Spectrum technology is used to find the direction of signals, the correlation between the signal source seriously affect the measured performance of the algorithm. To solve the condition of coefficient is equal to 1, many improved algorithms are presented, such as the spatial smoothing technique, Weighted spatial smoothing technique[2],SVD[3],Toeplitz[4,5] algorithm and so on. while these algorithms can solve the condition of coherent signal, When the signals are not coherent completely. Using these algorithms will undoubtedly generate unnecessary performance loss. If we can estimate correlation coefficient between the radio source, depending on the correlation coefficient to select algorithm, it can reduce unnecessary loss of performance. The correlation of the incident signal source will change in the dissemination process. Combining this changes with MUSIC algorithm undoubtedly will greatly improve the performance of traditional MUSIC algorithm[6-8]. So, to estimate the correlation between the signal source by using of array data received has a certain value and the value of engineering applications. In this paper , the thought of subspace decomposition will apply to estimate the correlation coefficient, getting the formula of the correlation coefficient between the signal source by the mathematical derivation Use of array receives data on the estimate of the correlation coefficient between the signal source and verify the effectiveness of the algorithm through computer simulation. It gets the correlation coefficient by the data that array received. Simulation results verify that this algorithm can be realized.

Signal Model for CC Estimation

Uniform linear array (ULA) of M antennas is considered in this paper. Assume that K narrowband far-field signals impinge on the array with directions of $\theta_1, \theta_2, \cdots, \theta_K$ .The output data vector of antennas can be shown as

$$\boldsymbol{X}(t) = \boldsymbol{A}\boldsymbol{S}(t) + \boldsymbol{N}(t) \tag{1}$$

Where $\boldsymbol{S}(t)$ is a K$\times$1-dimensional vector of signal-in-space. $\boldsymbol{N}(t)$ is a M$\times$1-dimensional vector of noise which is spatially white Gaussian noise with equal variance and is uncorrelated with

$\boldsymbol{S}(t)$. $\boldsymbol{A}=[\boldsymbol{a}(\theta_1),\boldsymbol{a}(\theta_2),\cdots,\boldsymbol{a}(\theta_K)]$ is a M×K-dimensional matrix called array manifold matrix, where $\boldsymbol{a}(\theta_i)=[1,\exp(-(j2\pi d\sin\theta_i)/\lambda),\cdots,\exp(-(j2\pi(M-1)d\sin\theta_i)/\lambda)]^{\mathrm{T}}$, λ is the wavelength of incident signal, d is the inter-element spacing which is set to be half a λ.

The covariance matrix of $\boldsymbol{X}(t)$ can be represented as

$$\boldsymbol{R}_x=\mathrm{E}\{\boldsymbol{X}(t)\boldsymbol{X}^{\mathrm{H}}(t)\}=\boldsymbol{A}\boldsymbol{R}_s\boldsymbol{A}^{\mathrm{H}}+\sigma_n^2\boldsymbol{I}_M \tag{2}$$

Where $\boldsymbol{R}_x$ is the covariance matrix of $\boldsymbol{X}(t)$, σ_n^2 is the covariance of noise, and $\boldsymbol{R}_s$ is the covariance matrix of $\boldsymbol{S}(t)$ which rests with the correlation between incident signals , it can represented as

$$\boldsymbol{R}_S=\mathrm{E}[\boldsymbol{S}(t)\boldsymbol{S}^{\mathrm{H}}(t)] \tag{3}$$

We can get the eigen-value decomposition of $\boldsymbol{R}_x$ as

$$\boldsymbol{R}_x=\boldsymbol{U}_S\boldsymbol{\Sigma}_S\boldsymbol{U}_S^{\mathrm{H}}+\boldsymbol{U}_N\boldsymbol{\Sigma}_N\boldsymbol{U}_N^{\mathrm{H}} \tag{4}$$

Where μ_i is the eigen values which meet the conditions of $\mu_1\geq\mu_2\geq\cdots\geq\mu_K\geq\mu_{K+1}=\cdots=\mu_M$, e_i and e_j are the corresponding eigenvectors, $\boldsymbol{U}_S$ and $\boldsymbol{U}_N$ are the corresponding eigenvector matrices which are named signal subspace matrix and noise subspace matrix respectively.

$\boldsymbol{\Sigma}=diag\{\mu_1,\mu_2,\cdots\mu_K,\mu_{K+1},\cdots\mu_M\}$ And $\boldsymbol{\Sigma}_S=diag\{\mu_1,\mu_2,\cdots\mu_K\}$, $\boldsymbol{\Sigma}_N=diag\{\mu_{K+1},\mu_{K+2},\cdots\mu_M\}$.

Signal Correlation Analysis

Coherent coefficient is a statistical analysis index which reflect the relevance degree between two variables. Assume $s_i(t)$ and $s_k(t)$ are two stationary signals, the correlation coefficient between them can be defined as

$$\rho_{ik}=\frac{\mathrm{E}[s_i(t)\overset{*}{s}_k(t)]}{\sqrt{\mathrm{E}[|s_i(t)|^2]\mathrm{E}[|s_k(t)|^2]}} \tag{5}$$

Easy to know that $|\rho_{ik}|\leq 1$, consider the multiple signals, the relationship between the signals can be divided into irrelevant, relevant or coherent according to the value of the correlation coefficient. The correlation between the signals are defined as follows: $\rho_{ik}=0$, $s_i(t)$ and $s_k(t)$ are independent; $0<\rho_{ik}<1$, $s_i(t)$ and $s_k(t)$ are positive correlation;$-1<\rho_{ik}<0$, $s_i(t)$ and $s_k(t)$ are negative correlation; $\rho_{ik}=\pm 1$, $s_i(t)$ and $s_k(t)$ are coherent.In order to simplify the signal model, scholars have often assumed that the signals are not related (the case of $\rho_{ik}=0$)or coherent (the case of $\rho_{ik}=\pm 1$) in array signal processing. However, in a real environment, The absolute value of the correlation coefficient between the signals often range between 0 and 1, this is discussed in the paper.

Correlation Coefficient Estimation Algorithm Based on Feature Subspace Decomposition

Right multiplicate matrix $\boldsymbol{U}_S$ around both ends of equation (4), get equation (6) as

$$\boldsymbol{R}_x\boldsymbol{U}_S=\boldsymbol{A}\boldsymbol{R}_s\boldsymbol{A}^{\mathrm{H}}\boldsymbol{U}_S+\sigma_n^2\boldsymbol{U}_S \tag{6}$$

Eigenvalue decomposition of data covariance matrix is shown as

$$\boldsymbol{R}_x=\boldsymbol{U}_S\boldsymbol{\Sigma}_S\boldsymbol{U}_S^{\mathrm{H}}+\boldsymbol{U}_N\boldsymbol{\Sigma}_N\boldsymbol{U}_N^{\mathrm{H}} \tag{7}$$

Right multiplicate matrix $\boldsymbol{U}_S$ around both ends of equation (7), we can get equation(8) as follow

$$\boldsymbol{R}_x\boldsymbol{U}_S=\boldsymbol{U}_S\boldsymbol{\Sigma}_S\boldsymbol{U}_S^{\mathrm{H}}\boldsymbol{U}_S+\boldsymbol{U}_N\boldsymbol{\Sigma}_N\boldsymbol{U}_N^{\mathrm{H}}\boldsymbol{U}_S \tag{8}$$

As we known, Signal subspace and noise subspace are orthogonal, and have follow equation

$$\boldsymbol{U}_S^{\mathrm{H}}\boldsymbol{U}_S = \boldsymbol{I} \tag{9}$$

So equation (8) can be simplified as

$$\boldsymbol{R}_x\boldsymbol{U}_S = \boldsymbol{U}_S\boldsymbol{\Sigma}_S \tag{10}$$

Observe the equation (6) and equation (8), we can obtained

$$\boldsymbol{A}\boldsymbol{R}_s\boldsymbol{A}^{\mathrm{H}}\boldsymbol{U}_S + \sigma_n^2\boldsymbol{U}_S = \boldsymbol{U}_S\boldsymbol{\Sigma}_S \tag{11}$$

And we can get the calculation formula as

$$\boldsymbol{R}_s = \boldsymbol{A}^{+}\boldsymbol{U}_S\boldsymbol{\Sigma}_S\boldsymbol{U}_S^{\mathrm{H}}(\boldsymbol{A}^{+})^{\mathrm{H}} - \sigma_n^2(\boldsymbol{A}^{\mathrm{H}}\boldsymbol{A})^{-1} \tag{12}$$

Where the "+" is pseudo-inverse matrix [8].

From formula (4) and (12), the value of correlation coefficient $\hat{\rho}_{ik}$ can be extracted from $\hat{R}_s$ through formula (13)

$$\rho_{ik} = \frac{\boldsymbol{R}_s(i,k)}{\sqrt{\boldsymbol{R}_s(i,i)\boldsymbol{R}_s(i,k)}} \tag{13}$$

Computer Simulation

The performance of provided algorithm is analyzed through simulations in this section. An 5-element uniform linear array is used and the inter-element spacing is half a wavelength. Assume that the noise is additive white Gaussian noise, and it not correlate with the signals.

Example 1. The validation of the algorithm

Two incident signals from 10º and 20º ,100 snapshots is used, and SNR is set to be -2dB, change the value of correlation coefficient, the mean value of 200 Monte Carlo trials corresponding to each value is shown as table 1.

Tab.1 The results of correlation coefficient estimation algorithm based on feature subspace decomposition

True value	Estimated value	MSE	True value	Estimated value	MSE
0.1	0.1103	0.0495	0.6	0.5913	0.0299
0.2	0.1990	0.0596	0.7	0.7016	0.0325
0.3	0.2897	0.0523	0.8	0.8052	0.0329
0.4	0.3927	0.0541	0.9	0.9858	0.1353
0.5	0.5097	0.0500			

Provable by Tab.1 , this method can be implemented to estimate the correlation coefficient between two incident signals, and the mean square error (MSE) of estimates is small, so this method can achieve correlation coefficient estimates.

Example 2.The relationship between MSE and the incident signals direction angular intervals

Assume the correlation coefficient between two incident spatial signals is 0.5 , 100 snapshots are used ,SNR= -2dB .Two incident spatial signals are recorded as $s_1(t)$ and $s_2(t)$, the direction of $s_1(t)$ as the reference is set to 0º, the direction of $s_2(t)$ gradually increase from 4.5 º to 10 º with the step value of 0.5 º , Figure 2 is the statistical experimental results of 200 independent experiments.

Figure 1 show that the MSE of this method tend to decrease with increasing angle interval of ,and when the angular intervals less than 4.5 º , the MSE exceeds 0.5 , it will can not detect the correlation coefficient between signal sources correctly, it means that the direction angular interval of the signal wave is reduced to a certain extent , the mutual influence between the incident signal will be particularly large, and thus it is unable to correctly estimate the correlation coefficient between the two signal sources .When the angular interval is greater than 5.5 º , which shows that when the incident angle interval between the signals is larger enough, the mutual influence between

signals is unconspicuous , thus the signals may be stable propagation relatively, and the correlation coefficient is not dramatic floating .

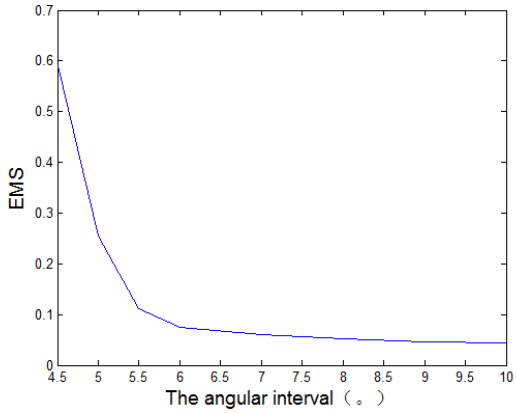

Fig. 1. The MSE changes with the angular interval

Conclusion

In array signal processing, however, since the received signal of array is the synthesized result of incident signals , the traditional correlation coefficient calculation method can't be applied.This paper provide a correlation coefficient estimation algorithm based on feature subspace decomposition. Simulation results verify that this algorithm can be realized to get the correlation coefficient .

Keywords: Multi-Consumer; E-commerce; Coordinative Optimization; Cultural Immune Algorithm

Abstract. To improve E-Commerce recommendation efficiency for multi-consumer population, coordinative optimization problem for multi-consumer purchase is studied. Multi-objective coordinative optimization model for multi-consumer purchase in E-commerce (MCOMMPE) is established, the optimization objectives consist of maximizing purchase probability, profit, green product orientation; minimizing lost consumer number; keeping equalization among varied purchase schemes. To solve easily, MCOMMPE is transformed into single objective optimization model. Cultural Immune Algorithm (CIA) is studied, affinity degree calculating, clone selecting, antibody population space and belief space are studied in detail, and the basic steps of CIA are designed. The validity of MCOMMPE and its CIA are validated.

Introduction

With E-commerce develops more and more profound, it bring much economic profit for E-commerce companies and social benefit. Coordinative optimization problem for multi-consumer purchase in E-commerce becomes the focus in E-commerce optimization control domain day by day. It is related with many factories, some coordinative contents consist of time coordination, discount term, goods item coordination, demand quantity coordination, green consume coordination etc. need to be considered. And many constraints need to be satisfied; it is a complex problem.

So far, some scholars have researched on E-commerce recommend, e.g., a recommender system based on the immune network is studied by Cayzer S, Aickelin U [1]. Electronic commerce recommender is applied by J B Schafer et al.[2]. Intelligence optimization algorithm or reasoning method is employed in many domains [3]. Artificial immune algorithm (AIA) is benefit for providing broad decision space on varied optimization problems, and it is broad applied in many domains day by day [4][5]. The knowledge structure of belief space in cultural algorithm can instruct evolvement process of AIA. Cultural algorithm is firstly proposed by Reynolds R G [6]. In cultural algorithm, knowledge for solving problem is obtained from evolvement population, and it is utilized for instructing population evolvement process, thus, search efficiency is improved.

AIA and Cultural algorithm are combined to solve above coordinative optimization problem for multi-consumer purchase in E-commerce in this paper.

Description and Establishment of Coordinative Optimization Model for Multi-consumer

Main objectives in Multi-objective coordinative optimization model for multi-consumer purchase in E-commerce (MCOMMPE) include maximizing purchase demand similarity degree, consumer value, web site profit, green product orientation; minimizing lost consumer number; equalization among varied purchase schemes. Main constrains include: (1) in each purchase scheme, there is a lowest price limit according to consumer's grade, there is also a acceptable upmost price limit from consumers; (2) total demand quantity of consumers should be less than present inventory level, and the lowest purchase scale should be reached;(3) goods due time of each consumer should be obeyed; (4) environmental protection features of should reach consumers' lowest requirement.

MCOMMPE is established as follows. Where, x_{ij} is 0-1 variable for judging whether consumer i select scheme j； N , M respectively denotes number of consumers and schemes; L_{ij} and U_{ij} denotes

the lowest price limit and acceptable upmost price of scheme j for or from consumer i; $Q_j^{(U)}$ and $Q_j^{(L)}$ respectively denotes inventory level and of lowest scale goods item in scheme j; s_{ij}, v_{ij}, q_{ij} and e_{ij} respectively denotes similar degree, consumer value purchase quantity, required environmental protection index of consumer i in purchase scheme j; $e^{(j)}$, d_j, c_j, p_j and $t^{(j)}$ respectively denotes environmental protection index, discount parameter, unit cost, unit price and supply period of scheme j; t_i and T_i respectively denotes purchase time, due date of consumer i; h(·) denotes scale economic function, $\mathrm{h}(x)=\alpha x/Q_j^{(U)}$, here, α=0.2.

$$\max f_1=\sum_{i=1}^{N}\sum_{j=1}^{M}x_{ij}s_{ij}/NM \tag{1}$$

$$\max f_2=\sum_{i=1}^{N}\sum_{j=1}^{M}x_{ij}v_{ij}/NM \tag{2}$$

$$\max f_3=\{\sum_{i=1}^{N}\sum_{j=1}^{M}x_{ij}p_j(1-d_j)-\sum_{i=1}^{N}\sum_{j=1}^{M}x_{ij}c_j[1-\mathrm{h}(\sum_{i=1}^{N}x_{ij}q_{ij})]\}/\sum_{i=1}^{N}\sum_{j=1}^{M}x_{ij}p_j(1-d_j) \tag{3}$$

$$\max f_4=\sum_{i=1}^{N}x_{ij}/NM \tag{4}$$

$$\max f_5=\sum_{i=1}^{N}\sum_{j=1}^{M}x_{ij}e^{(j)}/NM \tag{5}$$

$$\min f_6=\sum_{j=1}^{M}|\sum_{i=1}^{N}x_{ij}-\sum_{j=1}^{M}\sum_{i=1}^{N}x_{ij}/M\,|/NM \tag{6}$$

$$\text{s.t.}\quad L_{ij}x_{ij}\le p_j(1-d_j)x_{ij}\le U_{ij}x_{ij}\qquad i=1,2,\cdots,N \tag{7}$$

$$Q_j^{(L)}\le\sum_{i=1}^{N}q_{ij}x_{ij}\le Q_j^{(U)}\qquad j=1,2,\cdots,M \tag{8}$$

$$t_ix_{ij}+t^{(j)}x_{ij}\le T_ixi_j\qquad i=1,2,\cdots,N \tag{9}$$

$$e_{ij}x_{ij}\ge e^{(j)}\,x_{ij}\qquad j=1,2,\cdots,M \tag{10}$$

$$\{x_{ij}\mid x_{ij}=1,j=1,2,\cdots,M\}\in\Phi_i,\qquad i=1,2,\cdots,N \tag{11}$$

$$x_{ij}=0\text{ or }1 \tag{12}$$

As above the objective functions values is on interval (0,1), and the importance of each objective is same, the objective functions are integrated by multiplication and division approach. To reduce difficulty of algorithm encoding, Formula (8) is brought into objective function, therefore, the model is transformed as follows. Where, $\psi=+\infty$, when $x>0$, $\mathrm{sgn}(x)$=1, else, $\mathrm{sgn}(x)$=0.

$$\min f=f_6/\prod_{k=1}^{5}f_k+\psi\,\mathrm{sgn}(Q_j^{(L)}-\sum_{i=1}^{N}q_{ij}x_{ij})+\psi\,\mathrm{sgn}(\sum_{i=1}^{N}q_{ij}x_{ij}-Q_j^{(U)}) \tag{13}$$

s.t. formula (7), formulas from formula (9) to formula (12).

Principle and Design of Cultural Immune Algorithm (CIA)

$N\times M$ dimension 0-1 matrix is adopted to represent antibody of CIA. Affinity degree function between antibody i and antigen is defined as formula (14). Affinity degree function between antibody i and antibody j is defined as formula (15). Adjustment equation (as formula (16)) is employed to implement clone selection [1]. Where, n, ω_1, ω_2, ω_3, U_i and V respectively denotes number of antibodies, activity ratio, control ratio, death ratio, density of antibody i and antigen.

$$m_i=\mathrm{Aff}(Ab^{(i)},Ag)=1/f \tag{14}$$

$$m_{ik}=\mathrm{Aff}(Ab^{(i)},Ab^{(k)})=1-[\sum_{l=2}^{m}\sum_{j=1}^{n}|\,x_j^{(l)(i)}-x_j^{(l)(k)}\,|]/[\sum_{l=2}^{m}\sum_{j=1}^{n}|\,x_j^{(l)(i)}+x_j^{(l)(k)}\,|] \tag{15}$$

$$dU_i/dt=\omega_1m_iU_iV-\omega_2\sum_{j=1}^{n}m_{ij}U_iU_j/n-\omega_3U_i \tag{16}$$

Implement steps of CIA are as follows.

Step 1: Initialize antibody population space, antibody belief space, respectively generate H antibodies so as to form initial antibody population Ab, initial antibody belief population $\widehat{Ab}$.

Step 2: Calculate m_i by formula (14). Calculate m_{ik} by formula (15).

Step 3: Implement clone selection among every antibodies in Ab according to formula (16).

Step 4: Evolve antibodies. For antibody i, if its density $U_i < \beta$ (density threshold), dele antibody i, the number of deleted antibodies is recorded as H_d.

Step 5: If the acceptance operator iteration counter $C_{acc} = C_{ACC}$ (acceptance counter threshold), select r antibodies with highest m_i from antibody population Ab, and substitute r antibodies with lowest m_i from antibody belief population , C_{acc}=0; else $C_{acc} = C_{acc} + 1$.

Step 6: If the influence operator iteration counter $C_{\inf} = C_{\mathrm{INF}}$ (influence counter threshold), select r antibodies in random from belief antibody population $\widehat{Ab}$, and substitute r antibodies in antibody population Ab, $C_{\inf}$=0; else $C_{\inf} = C_{\inf} + 1$.

Step 7: If the density of h antibodies with highest density reaches density threshold, and leaning variance is less than variance threshold, or the maximal iteration, the learning process is end; else, generate H_d antibodies, repeat steps from step 2 to step 6.

Application Instance

To validate the validity of MCOMMPE and CIA, related data are collected. Related data on E-commerce purchase scheme are listed in table 1; data about consumer i are listed in table 2; s_{ij}, v_{ij}, q_{ij}, e_{ij} and one of the satisfied solutions obtained by CIA are listed in tables 3; L_{ij} and U_{ij} are omit for paper's length limit.

Conclusion

E-commerce recommend is an important content of E-commerce, it can bring much more profit to E-commerce companies. Thereby, MCOMMPE is significant to improve E-commerce efficiency. MCOMMPE and CIA are validated by applying instance. There is a broad application space for MCOMMPE, in which many demand and varied constraints are considered. There are some obvious features such as population diversity, non-prematurity and early constringency etc. in AIA, and there are also some obvious features such as clear search guiding, strong communicating between two layer space in cultural algorithm, therefore, AIA combing cultural algorithm will be benefit for solving complex optimization. Multi-objective dynamic coordinative optimization model introducing personal decision will be the future research trend on modeling aspect in this domain. AIA, cultural algorithm combing other algorithm mechanism will also be the future research trend on solving algorithm in this domain.

Keywords: Parcel Sea Map, automatic mapping, boundary data

Abstract. Parcel Sea Map mapping is currently implemented by manual, which causes the task tedious and error prone. To overcome this problem, this paper proposes an automatic mapping method for Parcel Sea Map. The boundary point data are basic mapping elements, which are obtained from sea cadastral survey. The mapping result can be demonstrated by two aspects: convex polygon and concave polygon. For convex polygon, well known left-turn and convex hull algorithms are adopted. For concave polygon, two algorithms are proposed. One is enumeration and the other is cutting algorithm. The above two mapping results can finally be determined by the inspector from sea cadastral survey. Experiments show that Parcel Sea Map automatic mapping can efficiently reduce the manual burden of present mapping.

Introduction

Sea cadastral [1] is books and maps which record the locations, boundaries, management authorities, areas, purpose and terms of service, sea levels, and standards of sea area usage for sea use of various projects. Parcel Sea is an enclosed sea use unit by ownership boundary lines. The basic task of sea use management for sea cadastral survey is to make a thorough investigation of the basic condition for every Parcel Sea. Parcel Sea is the fundament of sea cadastral survey. Parcel Sea Map is composed by boundary data and the use of sea characteristics. In regional marine planning, Parcel Sea Map is more changeable and high complexity. It is of importance for Parcel Sea Map automatic mapping by on-site boundary data. [2] proposed an automatic mapping for cadastral map of land, which only consider the condition of convex polygon.[3] provided an automatic mapping software for cadastral map of land. Data should be in a proper order. [4] proposed an improved and more efficient algorithm to calculate No-Fit Polygon. It can be used to solve two-dimensional nesting problems. [5] discussed inside mapping condition of surveying and mapping trade on the quick surveying of the Electronic Hero meter Total Station outdoor work.

Most existing literatures have two shortcomings :(1) only one kind of polygon was considered;(2) The polygon was unchanged after mapping. There was not a proper method for Parcel Sea map in open published literatures. Present method for Parcel Sea Map, in fact, is completed by manual that makes the task with heavy burden and can cause errors easily. To overcome the above problem, this paper presents an automatic mapping method for Parcel Sea Map. Two algorithms are firstly proposed for concave polygon mapping. Then a system design description is proposed for Parcel Sea Map.

Two proposed concave polygon mapping algorithms

Concave polygon automatic mapping is complicated in Parcel Sea Map. The more concave data are, the more concave polygons are. Two concave polygon mapping algorithms are proposed in the following. One is enumeration algorithm. The other is cutting algorithm.

2.1 proposed enumeration algorithm

The idea of proposed enumeration algorithm is that concave data are found firstly, and then try to find the first concave point and the rest concave data. All concave points are utilized in the same mapping procedure except the first concave point. The algorithm description is as follows:

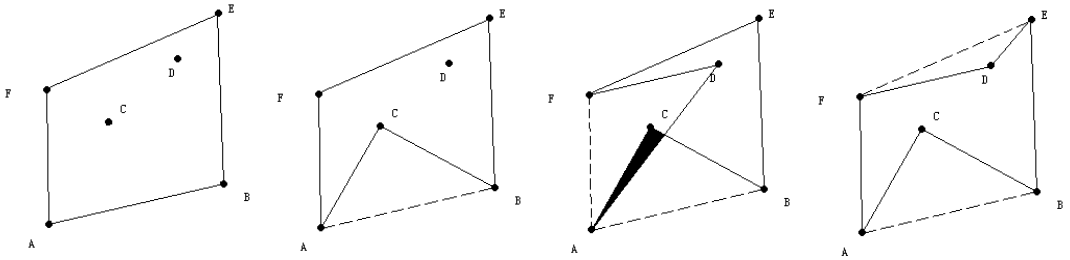
(a) To complete convex polygon mapping with convex data in array A by left-turn algorithm[6] or convex hull algorithm[7]. Then find concave data for (b).

(b) Find first concave data b, then insert it into array A. One side of polygon is breaked off. New two sides are generated by the first concave data b. Then new polygon sets are established.

(c) Find next concave data c with two points in one side of array A to construct a new triangle. If there is an intersect between the new triangle and polygon in array A, then find new side of A to construct a new triangle with this concave data c, repeat the procedure. If there is not an intersection, c is inserted into array A. Polygon sets are updated.

(d) Continue the same way for the rest concave points by step c until all concave points are inserted in array A.

The concave polygon enumeration algorithm mapping procedure is shown in figure 1. Concave points C and D is shown in (a). (b) is to find the first concave point to establish a new triangle ACB. (c) finds an intersection in shadow region. (d) constructs a new triangle FDE without intersection with concave polygon ACBEF.



(a) (b) (c) (d)

Fig.1. The procedure of concave polygon enumeration algorithm mapping from step (a) to (d)

2.2 proposed cutting algorithm

The main idea of cutting algorithm is to search for shortest distance between a concave data with one side of polygon, then break off that side and construct a new triangle. The algorithm description is as follows.

(a) To complete convex polygon mapping with convex data in array A . Then find concave data for (b).

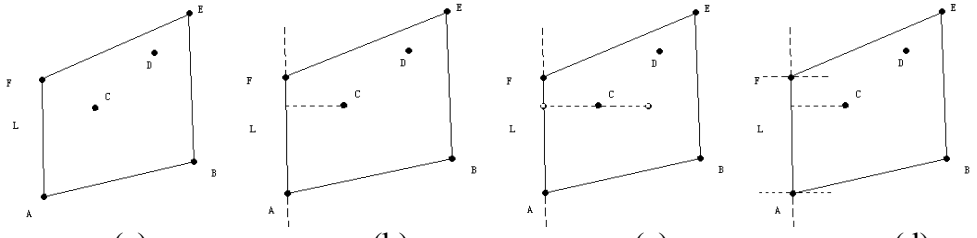
(b) Traverse array A and select a side L.

(c) Find concave point c which has shortest distance with side L in contrast to the rest points. Then project point c to side L.

(d) If the projection of point c is between the two terminal of side L, point c is inserted to array A to update array and end the loop.

(e) Find another concave point and repeat (c) and (d) until all concave points are inserted.

The concave polygon cutting algorithm mapping procedure is shown in figure 2. (a) demonstrates the concave points C and D.(b) is to find the projection of first concave point to side L.(c) determines the project whether between two terminals A and F. (d) constructs a new triangle FCA.



(a) (b) (c) (d)

Fig.2. The procedure of concave polygon cutting algorithm mapping from step (a) to (d)

A novel Parcel sea map automatic mapping algorithm description

The proposed automatic mapping can be described by Figure 3. We first choose data source and read longtitude and latitude of formatted data. Vector of GIS data set is generated. A left-turn algorithm is utilized to complete convex polygon mapping with automatic topological crossing correction. Then we try to determine the correctness of mapping results. If the results are correct, mapping is saved, otherwise, mapping still has to be conducted. The distance between rest points and adjacent side is calculated by the left-turn algorithm. The adjacent side is broken off and rest points are reconnected until all rest points are accomplished. Finally, we calculate the area and generate mapping.

Experiments

Experiment is conducted under C# with ArcGis platform under Windows 7 operating system. According to the interface of ArcGIS Engine, uncrossing automatic mapping algorithm can be completed by any group of data. All data is obtained from regional sea use information by National marine management dynamical monitoring system. All coordinates are firstly digitalized and unified by longitude and attitude. According to Figure 4 (a) and (b), we can find that multiple groups of points can be uncrossed by the proposed automatic mapping algorithm. The proposed mapping algorithm efficiently improves the mapping speed.

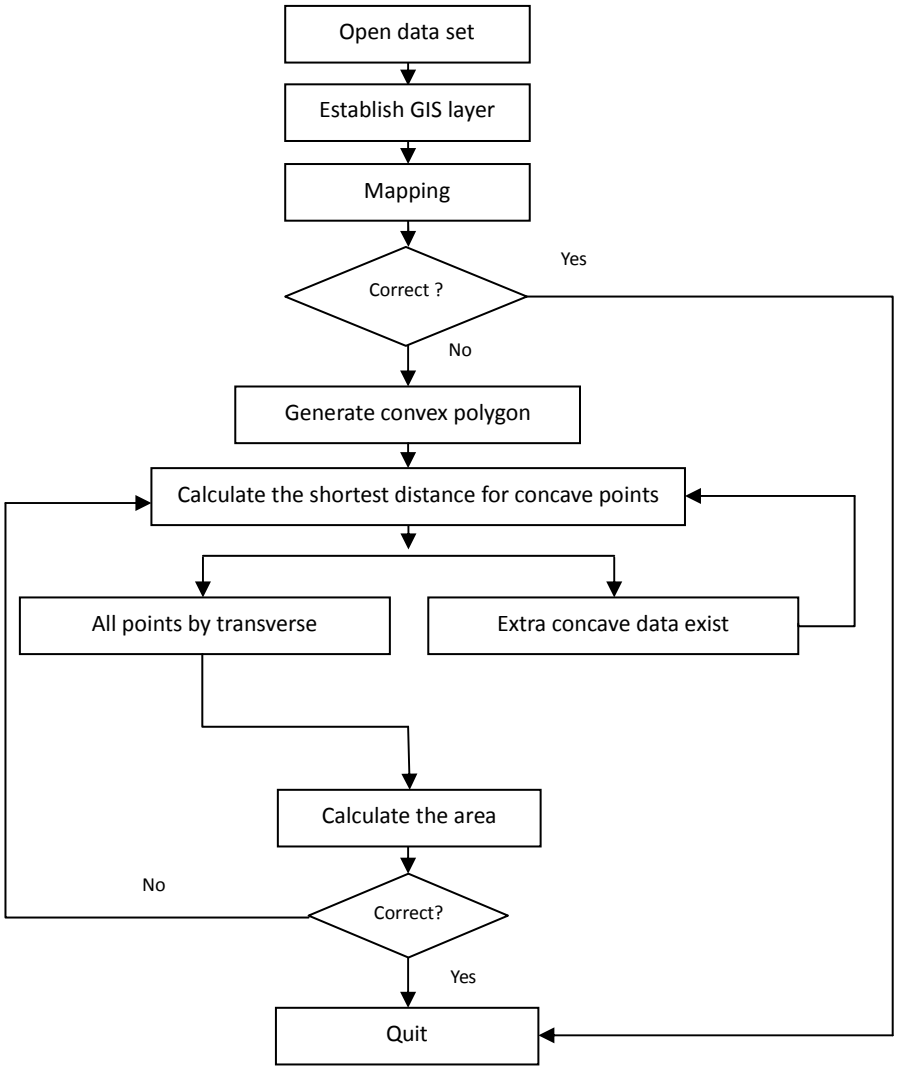


Fig. 3. Flowchart of Parcel Sea Map automatic mapping

(a) (b)

Fig.4. Experimental results of the proposed automatic mapping algorithm

Conclusion

In this paper, an automatic mapping method is proposed for Parcel Sea Map. The mapping result can be demonstrated by two aspects: convex polygon and concave polygon. For convex polygon, well known left-turn and convex hull algorithms are utilized. For concave polygon, two algorithms are proposed. One is enumeration and the other is cutting algorithm. The above two mapping results can finally be determined by the inspector from sea cadastral survey. Experiments show that Parcel Sea Map automatic mapping can efficiently reduce the manual burden of present mapping.

Keywords: Network Traffic Classification; Hadamard Matrix; ECOC; SVM

Abstract. The traditional network traffic classification methods have many shortcomings, the classification accuracy is not high, the encrypted traffic cannot be analyzed, and the computational burden is usually large. To overcome above problems, this paper presents a new network traffic classification method based on optimized Hadamard matrix and ECOC. Through restructuring the Hadamard matrix and erasing the interference rows and columns, the ECOC table is optimized while eliminating SVM sample imbalance, and the error correcting ability for classification is reserved. The experiments results show that the proposed method outperform in network traffic classification and improve the classification accuracy.

Introduction

Network traffic classification [1] can identify various applications, monitor and control the whole network, optimize network performance and improve the quality of service while keeping the network security. The traditional classification models play an important role in classification and identification in past decades, but have been unable to meet current demand when many incoming applications appear. So it is very necessary to search new method for network traffic classification.

In general, there are mainly four kinds of methods in network traffic classification: the first method is port numbers matching, through comparing the port numbers in TCP (UDP) packets with the well-known port numbers, the network traffic is classified. The authors of [2] used this method in network traffic classification, but the accuracy is not high. This port-based classification method is simple and easy to implement, but its accuracy is not high, and cannot recognize the network traffic which used dynamic ports or private protocol. The second method is to analyze the packet's payload, to check whether the packet contains certain features that are already known in some application. The authors of [3] and [4] improved the accuracy of the network traffic classification with the Content-based method. Compare with the port-matching-based method, the payload-analyzing-based method has the higher classification accuracy. But it has complex classification process and huge computational overhead, and cannot identify the encrypted traffic. The third method is host-behavior-based analysis; network traffic is classified by analyzing the behavior patterns of transport layer. [5] identified network traffic by analyzing the connection patterns of P2P flows. This method doesn't depend on port number and the payload of packet, therefore it is effective in encrypted traffic identification. But this method cannot identify the packet with encrypted heads of transport layer. The forth method is machine learning (ML), it classifies network traffic by identifying the flow-based statistical characteristics. This method can achieve higher accuracy and analyze encrypted data flow, so it is gradually becoming a hot topic for research. [6] established a network traffic model based on RBF neural network. [7] proposed a semi-supervised network traffic classification method which can adapt to known and unknown attack. [8] combined SVM with cluster algorithm, realized network traffic classification by using un-biased training and testing samples. [9] established SVM decision tree for network traffic classification. [10] reconstructed DDAG-SVM decision tree according to the class separation. [11] proposed a fast multi-class SVM based on binary encoding, and got higher classification speed with little loss of accuracy. In [12], Hadamard matrix and ECOC encoding table was generated using traditional recursive method, and was combined with SVM for multi-class classification.

In classification algorithms based on machine learning, the support vector machine (SVM) [13] is based on statistical learning theory, and successfully transforms the binary classification problem into a quadratic optimization by using nonlinear transformation and structure risk minimization principle. It has obvious advantages in the small sample size, nonlinear, multidimensional attribute classification, and has strong generalization ability and stability [14] while keeping high classification accuracy. The multi-class model of SVM is also widely used in classification [15]. But how to build a more efficient multi-class SVM model is the difficulty faced by researchers. So this paper presents a network traffic classification method based on optimized Hadamard Matrix and ECOC-SVM.

A New Network Traffic Classification Method based on Optimized Hadamard Matrix and ECOC-SVM

SVM is a typical binary classifier, being used in multi-class classification for network traffic, there are several methods at present: The first is one-against-all (OAA) method [16], it needs k SVM classifiers for k classes identification; but the shortcoming is the presence of area that may be overlapping or unclassifiable, further more the way of OAA classification in training phase makes the samples unbalanced and reduces the classification ability. The second is one-against-one (OAO) method [17], it needs $k(k-1)/2$ SVM classifiers for k classes identification, and classifies the samples according to the cumulative voting results of each SVM. There is no unclassifiable area, but the amount of SVM growths in square magnitude when the number of classes is increasing. So it is not suitable for the situation of classes being too much. The third method is DAG-SVM [10], it also needs $k(k-1)/2$ SVM classifiers for k classes classification in training phase, but each sample needs $(k-1)$ SVM at most in testing phase. This method is essentially the improvement for OAO method, and its shortcoming is prone to error accumulation, especially the selection for root node is very strict. The fourth method is multi-class-SVM based on error correcting output code(ECOC)[18], it binary divides the sample classes through building encoding matrix, and converts the question of k classes classification into that of m binary classifications ($2^{m-1} < k \le 2^m$). This method combines the advantages of ECOC and SVM, simplifies the difficulty of training, improves the accuracy of classification, and has certain error correction capability. Our approach in this paper is to modify the traditional ECOC-SVM, rebuild the ECOC encoding table through optimized Hadamard matrix, keep the hamming distance (i.e. the ability of being classified) between each class, and solve the question of sample imbalance by erasing the interference rows and columns.

(1) Theoretical analysis of proposed method:

The principle of classification based on SVM is expressed as formula (1), assume there is the training set $X = \{(x_1, y_1), (x_2, y_2), ..., (x_n, y_n)\}$, n is the number of samples, $x_i \in R^p (i = 1,2,...,n)$ is the i-th training sample, R^p is real vector, p is the dimension, $y_i \in \{+1, -1\}$ is the class label of training sample x_i. Through the SVM classifier $f(x)$, the training set X can be classified.

$$f(x) = \mathrm{sgn}\left\{\sum_{i-1}^{n} y_i \alpha_i^* K(x_i, x) + b^*\right\} \tag{1}$$

Where sgn is the symbolic function; $K(x_i, x)$ is linear function when X is linearly separable and is kernel function when X is not linearly separable; α_i^* and b^* is the optimal solution.

The principle of ECOC-SVM classification is binary dividing the sample classes through building encoding table of k rows and m columns, and converting the question of k classes classification into that of m binary classifications ($2^{m-1} < k \le 2^m$), the classification result is decided according to the principle based on minimum hamming distance. For instance, in the traditional classification process for 11 classes using 4 SVMs (the ECOC encoding table is express as table 1),

the encoding table only achieves corresponding relation from 11 classes to 4 SVMs, but the hamming distance between two adjacent rows is 1. E.g. the code value of first row is “0000” and the second row is “0001”, the hamming distance between them is 1, so there is no error correcting ability by this encoding method. Further more, if the number of classes is not an integer power of 2 (e.g. the number of network traffic classes in this paper is 11), the selection for encoding table is usually casual, and partly causes sample imbalance. For example, there are 11 classes in our network traffic sample, and we build encoding table as table 1, the classifier SVM1 contains 8 negative samples and 3 positive samples, there is seriously sample imbalance that reduces the classification performance.

Table 1 The traditional ECOC encoding table for eleven classes with four SVMs

Class	SVM1	SVM 2	SVM 3	SVM 4
1	0	0	0	0
2	0	0	0	1
3	0	0	1	0
4	0	0	1	1
5	0	1	0	0
6	0	1	0	1
7	0	1	1	0
8	0	1	1	1
9	1	0	0	0
10	1	0	0	1
11	1	0	1	0

In order to solve the above problem, [12] build encoding table with Hadamard matrix which is generated by recursive method, and increases the hamming distance between each rows (columns) at the cost of more SVMs. For instance in tables 2, there are 11 classes to be classified with 15 SVMs. This method first builds 16*16 Hadamard matrix, and erases the first column which contains only code value “0”, then selects the first 11 rows form matrix as encoding table. But this encoding method has also shortcomings, e.g. the column of SVM8 contains 8 negative samples ”0” and 3 positive samples ”1”, so there will still have sample imbalance in training phase which reduces classification ability. Moreover, when treating with k class samples, the classes of Hadamard matrix increase only in accordance with the integer power over 2, so it is lack of adaptability to the number of class. Further more, because the encoding table is built with the first k rows, the rows selecting is casual.

Table 2 The Hadamard ECOC encoding table for eleven classes with fifteen SVMs

Class	SVM 1	SVM 2	SVM 3	SVM 4	SVM 5	SVM 6	SVM 7	SVM 8	SVM 9	SVM 10	SVM 11	SVM 12	SVM 13	SVM 14	SVM 15
1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
2	1	0	1	0	1	0	1	0	1	0	1	0	1	0	1

9	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
10	1	0	1	0	1	0	1	1	0	1	0	1	0	1	0
11	0	1	1	0	0	1	1	1	1	0	0	1	1	0	0

(2) Algorithm Description of Proposed Method:

From above two methods, we can conclude that one perfect encoding method should meet the following conditions:

1) Row separation, that ensures the minimum hamming distance between each rows is maximum, so as to obtain the strongest error correcting ability;

2) Column separation, that ensures the hamming distance between each columns (includes its complement) is maximum, so as to eliminate the correlation between columns (i.e. SVM classifiers);

3) The numbers of two types of code values in each column should be nearly equal, so as to reduce the sample imbalance.

Based on above analysis, this paper presents an optimized encoding table based on Hadamard matrix. The specific approach is as follows:

Hadamard matrix has the following properties [19]:

1) It is orthogonal between different rows, so there is no correlation between them.

2) It is orthogonal between different columns, so there is no correlation between them.

3) In m-classes Hadamard matrix, the hamming distance between each row (column) is $m/2$ and which is already the biggest interval.

The definition of 2-classes Hadamard matrix is as follows:

$$H_2 = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \tag{2}$$

By recursive method, the N-classes Hadamard matrix can be obtained as follows:

$$H_N = \begin{pmatrix} H_{N/2} & H_{N/2} \\ H_{N/2} & -H_{N/2} \end{pmatrix} \qquad N = 2^i (i = 2,3,4,...) \tag{3}$$

This the traditional method for getting Hadamard matrix, the number of class N can only increases in the order $N = 2^i (i = 2,3,4,\cdots)$, i.e. $N = 4,8,16,32,64,...$ etc, so it is lack of adaptability to the number of class.

In this paper we rebuild the Hadamard matrix through the method mentioned in [19], and the classes of matrix N only needs to be: ① $N = 4i(i = 1,2,3,...)$, ② $(N-1)$ is a prime number. For example, assuming there are 11 classes to be classified. We first build 12-classes Hadamard matrix according to following steps:

1) Build the finite field $D = \{0,1,2,3,4,5,6,7,8,9,10\}$;

2) Get the square element D_0 from D, $D_0 = \{1,3,4,5,9\}$;

3) Get D_1 by plus 1 to the corresponding element of D_0, $D_1 = \{2,4,5,6,10\}$;

4) And so on, we get all from D_0 to D_{10};

5) Thus we can get 12-classes Hadamard matrix.

The 12-classes Hadamard matrix we have got is normative matrix, so each element in first row and first column is 1; this is no use for classification, so they are erased. Finally the optimized encoding table is consisted of the remained 11 rows and 11 columns, which is expressed in table 3.

Compared with the method used in [12], the class number of optimized Hadamard matrix N increases in the order $N = 4i(i = 1,2,3,...)$, so we can obtain $N = 4,8,12,16,20,\cdots$, etc. Compare with the previous $N = 4,8,16,32,64,\cdots$, etc, the available adjacent classes of matrix are more close. So the proposed encoding table has higher coding efficiency, and has better adaptability to the number of classes. Compared with table 2, the proposed encoding table only needs 11 SVM classifiers. It reduced 4 SVMs than before, and reduced the computation overhead in training and classifying phase. At the same time, the minimum hamming distance between each row is 6, with only small loss compared to the previous distance 8, and keeps the error correcting ability in most possible. The code value of each column is very balanced, that helps improve the performance of the classifier.

Table 3 The optimized Hadamard ECOC encoding table for eleven classes with eleven SVMs

Class	SVM 1	SVM 2	SVM 3	SVM 4	SVM 5	SVM 6	SVM 7	SVM 8	SVM 9	SVM 10	SVM 11
1	0	0	1	0	0	0	1	1	1	0	1
2	1	0	0	1	0	0	0	1	1	1	0
3	0	1	0	0	1	0	0	0	1	1	1
4	1	0	1	0	0	1	0	0	0	1	1
5	1	1	0	1	0	0	1	0	0	0	1
6	1	1	1	0	1	0	0	1	0	0	0
7	0	1	1	1	0	1	0	0	1	0	0
8	0	0	1	1	1	0	1	0	0	1	0
9	0	0	0	1	1	1	0	1	0	0	1
10	1	0	0	0	1	1	1	0	1	0	0
11	0	1	0	0	0	1	1	1	0	1	0

Experimental Results

We conduct experiments to demonstrate the feasibility of the proposed method with10-fold cross-validation 10-fold cross-validation10-fold cross-validation10-fold cross-validation10-fold cross-validation. Three other classification methods are used to conduct comparisons with our proposed method; they are DDAG-SVM [10], Binary Encoding Classifier [11] and Hadamard ECOC [12]. Experiment data is selected randomly from the network traffic samples used in [14], and there are totally 11 classes including 4580 samples were chosen. The experiment data is divided into 10 equal parts; we choose one part in turn as testing set and the rest 9 parts as training set, and conduct classification. Then repeat the above experiment 10 times; the average classification accuracy of each method is recorded in table 4. Comparison result shows that the proposed method increases the classification accuracy in contrast with the previous methods.

Table 4 Average classification accuracy with each method

DDAG-SVM	Binary Encoding	Hadamard ECOC	Proposed method
86.54%	88.17%	90.35%	91.43%

Conclusion

In this paper, a new network traffic classification method based on optimized Hadamard matrix and ECOC-SVM is proposed. Through restructuring the Hadamard matrix and erasing the interference row and column, the ECOC encoding table is optimized while eliminating SVM sample imbalance and the error correcting ability for classification is reserved. The experiments results show that the proposed method outperform the other three multi-class methods in network traffic classification and improve the classification accuracy.

Keywords: blind extraction; independent component analysis; nonsubsampled contourlet transform

Abstract. Most existing watermark extraction algorithms were dependent on prior knowledge. This paper proposed a blind extraction method without relying on prior knowledge. According to constructing new observation based on nonsubsampled contourlet transform, which utilizes low frequency and directional components of watermarked image, more independent components are generated. We involve these components into watermarked image and resort this solution to multichannel blind source separation. Estimated watermark is recovered by ICA algorithm. Experiment results indicate that the proposed method can achieve better results in contrast with two existing algorithms.

Introduction

Digital watermarking plays an important role in information hiding and protection [1]. Watermark extracting methods can be divided in three categories depending on whether the host image and the watermarking image are known, i.e., blind extraction, semi-blind extraction and non-blind [2]. The less prior knowledge is needed, the harder watermark extraction algorithm is.

Yu D et al. used blind source separation to detect and extract digital watermark. PCA and ICA were utilized to extract watermark while the algorithm needed the original image and the key [3]. Lin Q H etc proposed a fast image decryption algorithm, which evaluated the mixed coefficient of key images, then eliminated the key images. The number of source signals was reduced by half [4]. Nguyen T V and Patra J C put forward a blind extraction algorithm aimed at embedding watermark in spatial domain, named WMICAI [5]. Ma X etc presented extraction method based on redundant discrete wavelet transform, but it needed key which generated in embedding process [6]. Above algorithms had to utilize more or less prior knowledge. Shi X F and Hong Liang presented two blind extraction algorithms which constructed observation vectors respectively, based on discrete wavelet transform and redundant discrete wavelet transform, then applied ICA algorithm to extract the watermark images [7]. While instability still existed for various watermarks.

In this paper, a blind extraction algorithm for watermark image embedded by Discrete Cosine Transform (DCT) is proposed, based on nonsubsampled contourlet transform (NSCT). The observation vectors are constructed by watermarked image and each subband components of NSCT. Then by using independent component analysis, estimated host and watermark images are extracted without any prior knowledge. Experimental results demonstrate that proposed method can efficiently extract the watermark image and have better performance.

A novel blind watermark extraction algorithm based on nonsubsampled contourlet transform

The embedding watermark model by DCT [8] without key can be depicted as

$$I_w = f_{em}(I, W) \tag{1}$$

where I is the original host image, W is the watermark image, I_w is the watermarked image, f_{em} is the embedded process. If a_1 and a_2 respectively correspond to the linear coefficient of I and W, $o(I,W)$ is the nonlinear unit and regarded as noise. Then I_w can be described as

$$I_w = a_1 I + a_2 W + o(I,W) \tag{2}$$

Assume if $o(I,W)$ is omitted, (2) can be simplify further as

$$I_w = a_1 I + a_2 W \tag{3}$$

From (3), we can find that the model is similar to the single channel blind source separate (BSS) problem written as $X = AS$. If we want to solve (3) by BSS, an available way is to turn (3) into multi channel BSS. Hence it is necessary to construct another observation vector by some transform methods.

Nonsubsampled contourlet transform (NSCT) [9] has better characteristic in multiresolution, directionality and translation invariance in contrast with contourlet transform and wavelet transform. It is constituted by nonsubsampled pyramid (NSP) and nonsubsampled directional filter bank (NSDFB). Low frequency component I_{W1}, intermediate and high frequency component I_{W2} can be obtained after one scale NSP, four directional components $\left\{I_{w2}^{d1}, I_{w2}^{d2}, I_{w2}^{d3}, I_{w2}^{d4}\right\}$ can be expressed after four directional NSDFB by

$$\{I_{W1}, I_{w2}^{d1}, I_{w2}^{d2}, I_{w2}^{d3}, I_{w2}^{d4}\} = f_{NSCT}(I_w) = f_{NSCT}(a_1 I + a_2 W) \tag{4}$$

where f_{NSCT} is NSCT algorithm.

For the watermark information is embedded in the intermediate frequency bin by DCT and $\left\{I_{w2}^{d1}, I_{w2}^{d2}, I_{w2}^{d3}, I_{w2}^{d4}\right\}$ are mainly composed of intermediate and high frequency information, it is crucial to enhance watermark information that involve $\left\{I_{w2}^{d1}, I_{w2}^{d2}, I_{w2}^{d3}, I_{w2}^{d4}\right\}$ into original observation. In this way, the number of observed signals constructed is $m = 5$. In fact, the number of source signals is $n = 2$. Therefore we assume three virtual source signals which are nonlinear approximation $\left\{I_W^1, I_W^2, I_W^3\right\}$ of two source signals. The mixing process is simplified to be linear.

$$\begin{aligned}
I_{W1} &= b_{11}a_1 I + b_{12}a_2 W + a_{13}I_W^1 + a_{14}I_W^2 + a_{15}I_W^3 \\
I_{w2}^{d1} &= b_{21}a_1 I + b_{22}a_2 W + a_{23}I_W^1 + a_{24}I_W^2 + a_{25}I_W^3 \\
I_{w2}^{d2} &= b_{31}a_1 I + b_{32}a_2 W + a_{33}I_W^1 + a_{34}I_W^2 + a_{35}I_W^3 \\
I_{w2}^{d3} &= b_{41}a_1 I + b_{42}a_2 W + a_{43}I_W^1 + a_{44}I_W^2 + a_{45}I_W^3 \\
I_{w2}^{d4} &= b_{51}a_1 I + b_{52}a_2 W + a_{53}I_W^1 + a_{54}I_W^2 + a_{55}I_W^3
\end{aligned} \tag{5}$$

where b_{pq} and a_{ij} are respectively mixed coefficients, $p = 1,\cdots,5, q = 1,\cdots,5$ .So the observation can be written as

$$\begin{cases}
X_1 = I_w + I_{W1} = a_{11}I + a_{12}W + a_{13}I_W^1 + a_{14}I_W^2 + a_{15}I_W^3 \\
X_2 = I_w + I_{w2}^{d1} = a_{21}I + a_{22}W + a_{23}I_W^1 + a_{24}I_W^2 + a_{25}I_W^3 \\
X_3 = I_w + I_{w2}^{d2} = a_{31}I + a_{32}W + a_{33}I_W^1 + a_{34}I_W^2 + a_{35}I_W^3 \\
X_4 = I_w + I_{w2}^{d3} = a_{41}I + a_{42}W + a_{43}I_W^1 + a_{44}I_W^2 + a_{45}I_W^3 \\
X_5 = I_w + I_{w2}^{d4} = a_{51}I + a_{52}W + a_{53}I_W^1 + a_{54}I_W^2 + a_{55}I_W^3
\end{cases} \tag{6}$$

Since the observed signals are independent of each other, the mixing matrix is full rank. Fast fixed-point algorithm (FastICA) [10] is used to separate source signals $\left\{I', W', I_W'^1, I_W'^2, I_W'^3\right\}$. Five source signals are classified into two kinds of groups, original image class C_1 and watermark image class C_2. The centers of each class $K_1 = S_e', K_2 = S_f', e \in Na, f \in Na, f \neq e,\ Na = \{1,2,3,4,5\}$ are two signals with distance d_{uv} between each other farthest. d_{uv} can be described by

$$d_{uv} = \left\| S_u^{'} - S_v^{'} \right\|, u, v = 1,2,3,4,5, \mathrm{u} \neq \mathrm{v} \tag{7}$$

where $\|\cdot\|$ is a norm. S_e' , S_f' are respectively $S_u^{'}$ and $S_v^{'}$ corresponding to maximal d_{uv}.

The rest signals $S_j^{'}$ would be classified into C_1 or C_2 according to minimum distances d_{ij}.

$$d_{ij} = \left\| S_j^{'} - K_i \right\|, i = 1,2; j = 1,2,3 \tag{8}$$

if $d_{1j} \le d_{2j}$ is correct, $S_j^{'}$ belongs to class C_1, otherwise it belongs to C_2.

Estimated image S_1' and watermark image S_2' can be recovered by a weighted average which can be described as

$$S_1' = \sum_i^{cnt_1} C_{1i} \Big/ cnt_1 , S_2' = \sum_j^{cnt_2} C_{2i} \Big/ cnt_2 \tag{9}$$

where C_{1i} and C_{2i} are images which respectively belong to C_1 and C_2, cnt_1 and cnt_2 are numbers of each class.

The algorithm description of proposed method

a) Watermarked image is decomposed at different scales and directions by NSCT.

b) The constructed observations X are accumulations of watermarked image I_W and each component $\{I_{W1}, I_{w2}^{d1}, I_{w2}^{d2}, I_{w2}^{d3}, I_{w2}^{d4}\}$ at step a).

c) Applying FastICA algorithm to separate signals $\left\{I', W', I_W'^1, I_W'^2, I_W'^3\right\}$.

d) The separated signals are classified into two categories, the original class C_1 and the watermark class C_2, Center of each class is chosen by the farthest distance between each other.

e) The rest sources $S_j^{'}$ are classified into C_1 or C_2 by (8).

f) Extracted host image evaluation S_1' and watermark evaluation S_2' can be obtained by (9).

Experimental results

The performance measurement of the estimated watermark image is measured by normalized correlation (NC) [11] described as $NC = \sum_i^{M_W} \sum_j^{N_W} W(i,j) \hat{S}_2(i,j) \Big/ \sum_i^{M_W} \sum_j^{N_W} \left[W(i,j)\right]^2$. A watermark image is utilized and shown in Figure1 (a). Watermark image and host image are mixed by DCT. Figure1 (b) is the watermarked image after embedding process. Figure1 (c) is the extracted result by proposed method. Figure1 (d) is the binary image of Figure1 (c).

Fig. 1. Blind extraction results

Table. 1 Performance comparison with proposed algorithm and some existing algorithms

Methods	Proposed method	DWT	RDWT
NC value	98.80%	89.75%	96.26%

We conduct performance comparison with DWT and RDWT methods [8] in Table.1. From Table.1, we can find that proposed method outperforms than the other two methods.

Conclusion

This paper presents a novel blind watermark extraction algorithm, which doesn't need prior knowledge. Single channel blind source separate turns into multichannel problem by constructing new observation vectors based on nonsubsampled contourlet transform. Redundant source signals are separate by the ICA algorithm, which can reduce or eliminate irrelevant information through weighted average. Experimental result demonstrates that the proposed method can extract watermark effectively.

Keywords: RFID; Tag Anti-collision; Binary Search Algorithm; Dynamic Binary Search Algorithm; Improved Dynamic Binary Search Algorithm

Abstract. With the development of Radio Frequency Identification (RFID) technology, it also exposed some problems in practical applications. Especially in multi-tag anti-collision problem, how to quickly identify multiple tags in the scope of the reader has become the key to solve the problem. On the basis of the Binary Search Algorithm (BSA) and Dynamic Binary Search Algorithm (DBSA), the paper proposed an Improved Dynamic Binary Search Algorithm. The simulation result proves that the improved method in multi-tag anti-collision is more efficiency than the previous two, which is a good solution to the shortcomings of the first two algorithms.

Introduction

Radio frequency identification (RFID) technology was a rising non-contact automatic identification technology at the beginning of the 1990s that it used radio-frequency to make two-way communication by the way of non-contact. The RFID system mainly consists of three basic components: the tag, the reader and the host data processing system. Every tag has a global unique identification code (ID). When a tag enters the reader's RF range, it is driven on by induction and sends the stored ID code or other data from its inner memory to the reader. Reader can identify all tags within the interrogation zone of its antenna via wireless RF communication technology and algorithms [1]. In recent years, the RFID system has developed dramatically and has been adopted in many fields such as traffic, logistic, security and management [2] [3].

However, in the RFID system, one of the largest disadvantages is its low tag identification efficiency caused by tag collision [4] [5], that is, multi-tag collision is produced by multiple tags appearing simultaneously within a reader's interrogator range. Tag anti-collision algorithm usually consists of the following four methods: SDMA (Space Division Multiple Access), FDMA (Frequency Domain Multiple Access), TDMA (Time Domain Multiple Access) and CDMA (Code Division Multiple Access). But for the low cost and ease of implementation, TDMA is most commonly used. Anti-collision algorithm using TDMA is divided into two ways: deterministic and non-deterministic anti-collision algorithm, and the latter is also called random anti-collision algorithm [6]. The latter was chosen, which was mainly based on the Binary Search Algorithm.

The paper described the Binary Search Algorithm (BSA) and the Dynamic Binary Search Algorithm (DBSA), and put forward an Improved Dynamic Binary Search Algorithm (IDBSA). MATLAB simulation is applied to compare the performance of these three algorithms.

Binary Search Algorithm (BSA)

Binary Search Algorithm (BSA) was comprised of the specified commands and rules between reader and multiple tags.

The following example illustrated the anti-collision principle and process of the BSA.

Assuming that there were four tags, Tag1 (10110010), Tag2 (11100010), Tag3 (10110011), Tag4 (10100010) and the length of every tag was 8 bits. Bits were defined as D7, D6, D5, D4, D3, D2, D1 and D0 from the high-order bit to the low-order one. The reader sent a request command (11111111), and all the tags were in response to this request. The reader received the sequence number 1?1?001?, ? represented the position of the collision. The reader switched the value of the collided highest bit to logic "0", the other low-order bits were changed into logic "1", that was, D6= 0, the sequence number was 10111111. Then the reader transmitted the request again to the tag. The tags that were less than 10111111 were in response to the reader's request. The reader received the returning serial number 101?001?, the highest position of the collision was transformed as logic "0", and the remaining low positions were 1, that is, D4=0. Then the reader repeated the above process. Finally, the reader recognized serial number 10100010(tag4) successfully, replying the select command and reading the data, and the tag was set in the unselected state. Unambiguous identification process was shown in the following table1.

Tab.1 The specific identification process of BSA

Req_count	First	Second	Third	Select	Read &Write
Req_com	11111111	10111111	10101111		
Returning data	1?1?001?	101?001?		10100010	
Tag1(10110010)		10110010			
Tag2(11100010)					
Tag3(10110011)		10110011			
Tag4(10100010)		10100010	10100010		10100010

From the workflow of the BSA (Req_count is short for Request count, Req_com is short for Request command), it can be seen that the more the tags are, the more the searching numbers that the reader identified the tag successfully are, the longer the time consumes. If the reader wants to recognize a tag from *N* tags, the numbers of commands requiring to send *f(N)* are:

$$f(N) = \log_2 N + 1 \tag{1}$$

So the numbers of all commands that the reader recognizes all tags are:

$$I = f(1) + f(2) + f(3) + \cdots + f(N-1) + f(N)$$

$$I = (\log_2 1 + 1) + (\log_2 2 + 1) + \cdots + \log_2 (N-1) + 1 + \log_2 N + 1 = N + \log_2 (N!) \tag{2}$$

Dynamic Binary Search Algorithm (DBSA)

After the tag received a request command from the reader, the sequence number was always transmitted in full. In practical applications, the tag serial number was very large, not only eight bits as mentioned above. Then it would waste a lot of time. So some researchers have put forward a Dynamic Binary Search Algorithm to deal with data-transmit load. In this algorithm, the reader only needed to transmit the bits of the ID which it already knew, and the tags were in response to the reader with the rest bits of the ID that the reader didn't know [7].

Its searching numbers were the same as the BSA, but it still couldn't efficaciously deal with the situation when there were huge numbers of tags.

An Improved Dynamic Binary Search Algorithm (IDBSA)

The principle (given the length of the tag is 8 bits.) is：

(1) Request——this command sends a set of serial numbers as a parameter to the tag. The tag makes a comparison between its sequence number and the received sequence number. The tag will transmit it to the reader when its own serial number is not greater than the received sequence number; otherwise, the tag will not respond to the reader's commands. This helps to narrow the range of prospecting tags.

(2) Select——the fourth prefix that the serial number collided is remained, and the bits collided are set as logic "1".The rest fourth bits are no use. Then the fourth prefix of the serial number sent by the reader is similar to the tags', which are identified successfully.

(3) Sleep——after completing the communication between the selected tags and reader, the reader run this command to make the tag to be in the sleep state, no longer respond to any commands. Then the reader repeats the above process.

For example, there were 8 tags in the interrogation area of the reader. Their serial numbers were tag1(11110001), tag2(11110011), tag3(11010001), tag4(11010011), tag5(10110001), tag6(10110011), tag7(10100001), tag8(10100011). Bits are defined as D7, D6, D5, D4, D3, D2, D1 and D0 from the high-order bit to the low-order one.

The first step: The reader sent a Request command (11111111) to all tags, which responded to this request. The reader received the sequence number 1???00?1, ? represented the position of the collision.

The second step: The collision bits D6, D5, D4 were set as logic "1", and then the reader transmitted the returning serial number 1111 to the tags. The tags that were well as receiving serial number were detected, that is, tag1and tag2 were identified. Then they were inactive and set in the sleep state.

The third step: The reader sent the Request command (1101). As same as the second step, tag3 and tag4 responded to the reader. Then they were set in the sleep state.

The fourth step: The reader sent the Request command (1011). As same as the second step, tag5 and tag6 responded to the reader. Then they were set in the sleep state.

The fifth step: The reader sent the Request command (1010). As same as the second step, tag7 and tag8 responded to the reader. Then they were set in the sleep state. Until now, all tags were identified successfully.

The workflow was shown as the following table2.

Tab.2 The workflow of IDBSA

Req_count	First	Second	Third	Forth	Fifth
Req_com	11111111	1111	1101	1011	1010
Ret_ data	1???00?1	111100?1	110100?1	101100?1	101000?1
Tag1(11110001)		11110001			
Tag2(11110011)		11110011			
Tag3(11010001)			11010001		
Tag4(11010011)			11010011		
Tag5(10110001)				10110001	
Tag6(10110011)				10110011	
Tag7(10100001)					10100001
Tag8(10100011)					10100011

As showed in the table (Req_count is short for Request count, Req_com is short for Request command), the number of tags within the asking range of the reader is two when the collision bit number is one, the total searching times $S(N)$ $(N=2^n)$ can be expressed as:

$$S(N) = 2^{n-1} + 1 = 2 \quad (n = 1) \tag{3}$$

The number of tags within the asking range of the reader is less than four when the collision bit number is two, the total searching times are:

$$S(N) = 2^{n-1} + 1 = 3 \quad (n = 2) \tag{4}$$

According to the mathematical induction, when there are n collision bits and the number of tags is N, the total searching times are:

$$S(N) = 2^{n-1} + 1 \quad (n \geq 1) \tag{5}$$

So, the average searching times $L(N)$ $(N=2^n)$ for every tag are:

$$L(N) = S(N) / N = (2^{n-1} + 1) / 2^n \quad (n \geq 1) \tag{6}$$

Simulation result

Put the calculation formula (2) and (5) into MATLAB simulation, assuming the total numbers of tag N is from 2 to 256, the results are shown in Figure2. The solid line represents the searching time of BSA and DBSA and the dashed line represents the searching time of IDBSA.

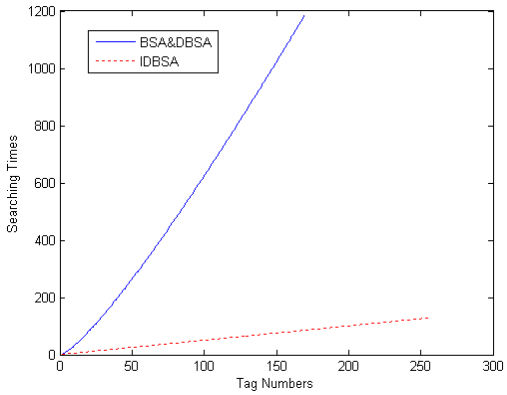

Fig.1 Simulation results

Known from the above figure1, when the number of tags is certain, the average searching times of the Improved Dynamic Binary Search Algorithm are quite less than Binary Search Algorithm and Dynamic Binary Search Algorithm. With the increase in the number of tags, this effect is more pronounced.

Conclusion

Based on the analysis of the principle and the simulation results, it is concluded that the ability of dealing with multiple tags of the Improved Dynamic Binary Search Algorithm is stronger than Binary Search Algorithm and Dynamic Binary Search Algorithm. So Improved Dynamic Binary Search Algorithm overcomes multi-tag collision to a great extent.

Keywords: Nonlocal Nonlinearity; Optical Beam; Beam Propagation; Interaction

Abstract. The interaction of two four-petal Gaussian beams propagating in strongly nonlocal nonlinear media is investigated. The results show that the intensity evolution of two beams during their propagation is periodical, which is similar to that of a single beam propagation. However the combined optical field of two beams during propagation is more complicated than that of a single beam. During propagation, the two beams are attracted each other, and at the superposed region of two optical fields, the interference fringes appear. The influences of different beam orders and different input powers on the propagation properties are also discussed.

Introduction

Since 1997, the nonlocal soliton was proposed, various nonlocal solitons are found, such as Gaussian solitons, Hermite and Laguerre Gaussian solitons, complex-variable-function-Gaussian solitons, Ince-Gaussian solitons, vortex solitons, surface soliton and so on. These new types of solitons do not exist in local nonlinear media. Nonlocal solitons exhibit many unique properties, such as the attraction between two out-phase solitons [1, 2], the large phase shift [3, 4], the long-range interactions between nematicons [5]. Nonlocality is ubiquitous in nature, many media demonstrate this property such as atomic vapors, photorefractive media, Bose-Einstein condensates etc. Up to now, peoples have found that the lead glasses and the nematic liquid belong to the strongly nonlocal nonlinear media. In recent years, the propagation properties of optical beams in nonlocal nonlinear media have attracted sufficient attention. Some nonlocal optical beams are investigated.

On the other hand, the propagation properties of four-petal Gaussian beams in various optical systems are studied since it is proposed by Duan et al in 2006 year [6]. Zhou et al analysed the vectorial structure of the far-field of an apertured four-petal Gaussian beam [7] and given M^2 factor of four-petal Gaussian beam [8], Tang et al studied the propagation of four-petal Gaussian beams in apertured fractional Fourier transforming systems [9]. In addition, the propagation properties of a single four-petal Gaussian beam in strongly nonlocal nonlinear media are investigated in detail [10]. However, to the best of our knowledge, the interaction between two four-petal Gaussian beams remains unexploited. In this paper, the interaction of two four-petal Gaussian beams propagating in strongly nonlocal nonlinear media is investigated in theory. Some numerical simulations are performed, and the intensity evolutions of the combined optical field of two beams are given. Furthermore the influences of beam order and input power on the intensity evolutions are discussed.

Theory

In strongly nonlocal nonlinear media, the nonlocal nonlinear Schrodinger equation can be deduced to the Snyder–Mitchell linear model which is expressed as the following equation in Cartesian coordinates [1, 3, 10].

$$2ik\frac{\partial \Phi}{\partial z}+\Delta_{\perp}\Phi-k^2\gamma^2P_0\left(x^2+y^2\right)\Phi=0, \tag{1}$$

where k is the wave number in the media without nonlinearity, Φ is the complex amplitude of the paraxial optical beam, $\Delta_\perp = \left(\partial^2/\partial x^2 + \partial^2/\partial y^2\right)$ is the two-dimensional transverse Laplacian operator, γ is a material constant associated with the nonlocal response function of the media, $P_0 = \iint |\Phi|^2 \, dxdy$ is the input power of the beam.

The four-petal Gaussian beam proposed by Duan and Lü [6] at the source plane is expressed as,

$$\Phi(x_0, y_0, 0) = C_0 \left(\frac{x_0 y_0}{w_0^2}\right)^{2n} \exp\left(-\frac{x_0^2 + y_0^2}{w_0^2}\right), \tag{2}$$

where C_0 is a normalized constant and ensures the input beam power equals P_0, w_0 is the waist width of a Gaussian beam at the initial plane, n is the beam order. For a single beam propagating in strongly nonlocal nonlinear media, it can be regarded as a self-induced fractional Fourier transform [11, 12]. As a result, the expression of a four-petal Gaussian beam in strongly nonlocal media can be obtained using the following integral formula

$$\begin{aligned}\Phi(x, y, z) = &\frac{ik\sqrt{\gamma^2 P_0}}{2\pi \sin\left(\sqrt{\gamma^2 P_0} z\right)} \exp\left[-\frac{ik\sqrt{\gamma^2 P_0}\left(x^2 + y^2\right)}{2\tan\left(\sqrt{\gamma^2 P_0} z\right)}\right] \\ &\times \iint \Phi(x_0, y_0, 0) \exp\left[\frac{ik\sqrt{\gamma^2 P_0}}{2\tan\left(\sqrt{\gamma^2 P_0} z\right)}\left(x_0^2 + y_0^2\right) - \frac{ik\sqrt{\gamma^2 P_0}}{\sin\left(\sqrt{\gamma^2 P_0} z\right)}\left(x x_0 + y y_0\right)\right] dx_0 dy_0\end{aligned} . \tag{3}$$

Based on Eqs. (1)-(3), the propagation of a single four-petal Gaussian beam in strongly nonlocal media can be investigated, and the propagation properties can be found in Ref. [10]. However the interaction between two four-petal Gaussian beams remains unexploited in Ref. [10]. We assume the beam centers of two four-petal Gaussian beams at the initial plane are located at $(\pm d, 0)$, namely

$$\Phi_\pm(x_0, y_0, 0) = C_0' \left[\frac{(x_0 \pm d) y_0}{w_0^2}\right]^{2n} \exp\left[-\frac{(x_0 \pm d)^2 + y_0^2}{w_0^2}\right]. \tag{4}$$

Because the beam propagation in strongly nonlocal media can be regarded as a self-induced fractional Fourier transform, the interaction of two beams co-propagating in such media can be discussed by using the linear rule and the shift rule of the fractional Fourier transform [11, 12], i.e.

$$\hat{F}_\alpha\left\{C_1 g(\xi) + C_2 h(\xi)\right\}(x) = C_1 \hat{F}_\alpha\left\{g(\xi)\right\}(x) + C_2 \hat{F}_\alpha\left\{h(\xi)\right\}(x) \tag{5}$$

$$\hat{F}_\alpha\left\{g(\xi + C_3)\right\}(x) = \exp\left[iC_3 \sin\alpha\left(x + \frac{C_3 \cos\alpha}{2}\right)\right] \hat{F}_\alpha\left\{g(\xi)\right\}(x + C_3 \cos\alpha) \tag{6}$$

where $\hat{F}_\alpha$ represents the fractional Fourier transform, C_1, C_2, and C_3 denote constants, α is the fractional order of the fractional Fourier transform. In the following, based on Eqs. (2)-(6), some numerical simulations are performed, and the interaction of two four-petal Gaussian beams in the strongly nonlocal media is investigated, especially the transverse intensity distributions on different propagation distances.

Numerical Simulations

Fig. 1 gives the transverse intensity distributions of two four-petal Gaussian beams co-propagating in strongly nonlocal media with the input power being ciritical power P_c. It is found that the evolution of two beams is periodical. The period is πz_p, where $z_p = \sqrt{P_{gc}/P_0}\, z_R$, P_{gc} is the critical power of a Gaussian beam [3], z_R is the Rayleigh distance of a Gaussian beam.

With the propagation distance increasing, the energy converges to the beam center gradually. Some intensity peaks appears at $z = 3\pi z_p/6$, and the shapes of the intensity peaks is similar to a single four-petal Gaussian beam. Then the beam evolves as an inverse process from $z = 0$ to $z = 3\pi z_p/6$. These properties are similar to a single four-petal Gaussian beam. However the combined optical field of two beams during propagation is more complicated than that of a single beam. During propagation, the two beams are attracted each other, and at the superposed region of two optical fields, the interference fringes appears.

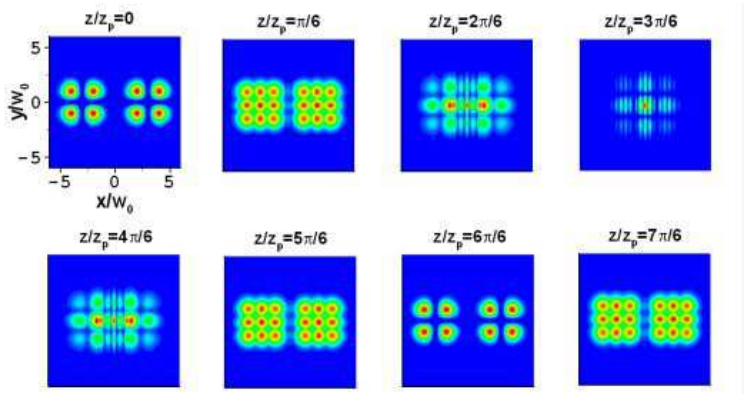

Fig.1. Transverse intensity distributions of two four-petal Gaussian beams co-propagating in strongly nonlocal media at different propagation distances given on the top. Parameters: $d = 3w_0$, $n = 1$, $P_0 = P_c$.

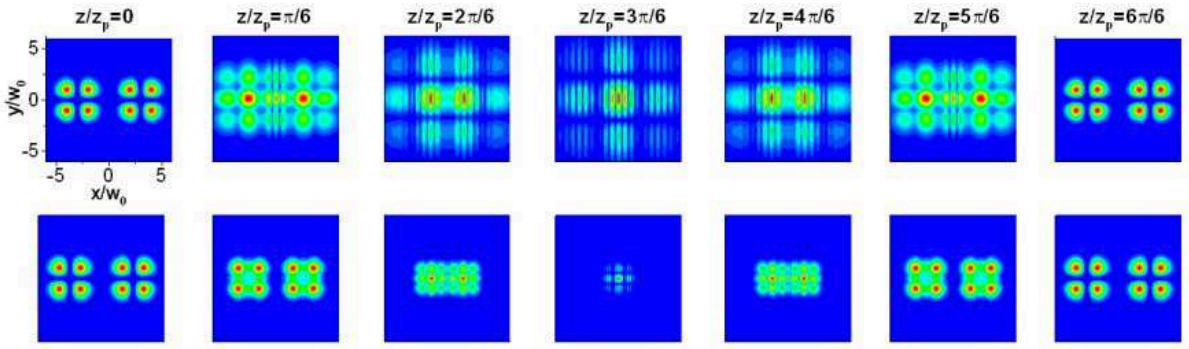

Fig.2. Influence of the input power on the transverse intensity distributions. Top row: $P_0 = 0.5P_c$, Bottom row: $P_0 = 2.0P_c$. The other parameters: $d = 3w_0$, $n = 1$.

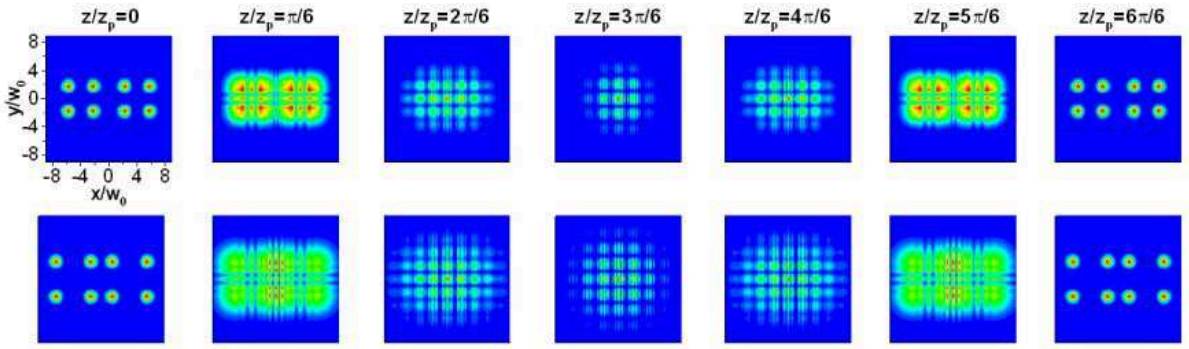

Fig.3. Influence of the beam order on the transverse intensity distributions. Top row: $n = 3$, Bottom row: $n = 6$. The other parameters: $d = 4w_0$, $P_0 = P_c$.

Figs. 2 and 3 illustrate, respectively, the influences of the input power and the beam order on the transverse intensity distributions. It is found that from Fig. 2 that the beam is broadened when the input power is weaker than the input power, and it is compressed when the input power is higher than the critical power, because the higher input power provides a stronger nonlinearity. In Fig. 3 the input power each beam equals its own critical input power. Fig. 3 shows that for a higher beam order, the combined optical field of the two beams becomes more complicated during propagation and more intensity peaks appear at $z = 3\pi z_p / 6$.

Conclusion

In conclusion, the interaction of two four-petal Gaussian beams in strongly nonlocal media has been studied. The results show that the propagation properties of two four-petal Gaussian beams co-propagating in strongly nonlocal media is similar to those of a single beam, but the combined optical field of two beams is more complicated than that of a single beam. During propagation, the two beams are attracted each other, and at the superposed region of two optical fields, the interference fringes occurs. The influences of different beam orders and different input powers on the transverse intensity distribution are discussed.

Keywords: Sentiment Tendency; Analysis; Sentiment dictionary; Support Vector Machine

Abstract. With the rapid development of network, texts which contain position, views and opinions of events are exploding. Texts of review contain author's feelings, views and tendencies the author wants to express. People need to analyze these texts automatically to acquire sentiment tendency of the author. This paper presents a model for automatic text analysis about sentiment tendency on comment text. The model combines algorithms based on emotional dictionary and Support Vector Machine learning algorithm together, which takes advantage of both algorithms.

Introduction

Information on the internet is increasing. More and more users are willing to share opinions on microblogs, blogs, forums and other platforms to exchange ideas and emotions which include a large number of users' comment on events, products, people and other objects. Government agencies can master social group psychology after emergencies to monitor public opinions. What's more, sentiment analysis can be used to provide psychological counseling for high-pressure groups. The way to mine semantic information from massive unstructured comment texts revealing the author's views and feelings has become a hot research direction. So that people quickly get the author's sentiment tendency.

In previous studies, sentiment classification is also known as opinion mining. Text sentiment classification is defined by mining and analyzing subjective information such as position, viewpoint and emotion in texts to judgment sentimental category. From the present studies, literatures on sentiment classification methods are broadly divided into two categories.

(1) Use sentiment dictionary to analyze text sentiment.

A sentimental word has sentiment tendency in the text, which is an important basis for judging the sentiment tendency. Sentimental words can be divided into positive and negative sentimental words generally, which also be called commendatory and derogatory term. Sentiment dictionary is a collection of sentimental words, consisting of two parts: commendatory and derogatory term dictionary. There exists sentiment dictionary such as HowNet, Student Judgments Justice Dictionary, Synonyms Cilin, NTUSD and so on.

Studies of text sentiment analysis abroad began in the late 1990s. Riloff and Shepherd researched how to build a semantic dictionary based on corpus database[1]. Turney used mutual information method to extend basic judgments vocabulary, and polar emotional semantics (ISA) algorithm was used to analyze the sentiment in texts. Their accuracy reached 74% when dealing with common corpus data[2]. Yang Chao, Feng Shi put forward a network public opinion analysis method based on sentiment dictionary expansion technology[3]. HowNet sentiment dictionary and NTUSD were extended respectively. Wang Suge put forward a text classification method based on emotional empowerment of rough membership, which utilized characteristic tendency strength and defined empowerment rough membership[4].

(2) Use machine learning methods to analyze text sentiment.

B.Pang used machine learning techniques to determine sentiment tendency. Three methods contained Support Vector Machine (SVM), Naive Bayes (NB), Maximum Entropy were used to judge the effect of sentiment tendency. However, experimental results showed that the SVM classification behaved best[5][6]. As we all know, the basic machine learning algorithms includes Support Vector Machine (SVM), Naïve Bayes, K nearest neighbor (KNN), simple linear classifier

(SLC), the maximum entropy (ME), etc[7][8]. Xia Huosong calculated rights by TF-IDF, used SVM classifier based on RBF kernel function to do analysis on network customer comments. Effects of stop words in sentiment classification were studied in his paper[9]. Qiao xiangjie got the reasoning about students' expectations on learning events based on fuzzy reasoning methods. What's more, he did experiments on his model throw Bayes network to test the reasonableness of the model[10].

The advantage of using sentiment dictionary to analyze the text sentiment is the precise fine-grained classification on word level and sentence level. However, limited by natural language processing techniques and related extracting technologies, this method is easy to lose important hidden mode in data sets. The key of machine learning method is located on extracting feature information effectively. Its advantage is objective knowledge acquisition, high accuracy. In the opposite, the disadvantage is the relatively high dependence of training corpus and longer training cycle.

Design of the model on sentiment tendency analysis

According to different levels, sentiment tendency analysis can be divided into the following four levels which are words and phrases level, sentence level, chapter level, as well as the overall sentiment tendency of vast amounts of information. This paper mainly analyzes the tendency for sentence level sentiment, and extracts kinds of subjective information in sentence. A model of sentiment tendency analysis is introduced below.

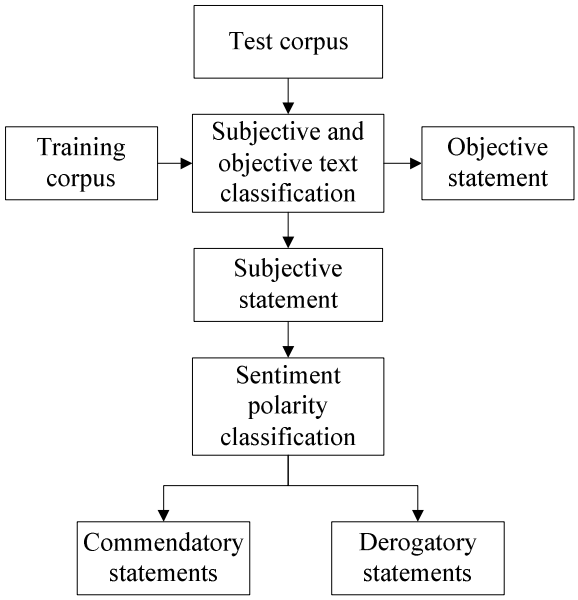

Fig.1. Model of sentiment tendency analysis

Task of this paper is to judge author's sentiment into three categories including praise, derogatory, neutral position based on the sentiment tendency of statements. Usually two programs are taken in previous studies. The one program is using classifier to classify test corpus directly. The other one is calculating the sentiment weight of each statement under considering the case of context. It sets the threshold value according to the size of sentiment weight, and divides sentence into positive, neutral, negative sentiment according to whether the sentiment weight is greater than the threshold value. Both programs have their advantages and disadvantages. Therefore, we propose a hierarchical model for sentiment classification. In the first layer we make subjective and objective dichotomous on texts, extracting subjective sentences. In the second layer we make sentiment polarity classification of the subjective sentence, namely the commendatory derogatory classification, and calculate the intensity of sentiment. Different classification algorithms are adopted in each layer to ensure the accuracy of the respective layers.

The detailed algorithm

(1) Subjective and objective text classification:

Support Vector Machine (SVM) was proposed by Vapnik since 1995, which was subjected to double emphasis on theory and applications areas. It has a solid statistical theory foundation and demonstrates the effectiveness of good practice in many practical applications. When carrying out subjective and objective text classification, we choose SVM algorithm to divided statements into two categories that is subjective statements, objective statement. The algorithm process is introduced as follows.

Step 1: Corpus preparation. Collect and label training data and test corpus, requiring that the scale of different types of training corpus should be roughly equal due to the characteristics of SVM classification algorithm.

Step 2: Corpus pretreatment. This section includes corpus segmentation, tagging, deleting stop words and so on.

Step 3: Select feature vectors. In this paper document frequency (DF) is applied to choose feature vectors.

Step 4: Make training documents into vector representation depending on selected features.

Step 5: Take the document of vector form into SVM classifier for training, deriving the training model.

Step 6: Represent corpus to be classified into vector format according to the optional feature vector by training corpus.

Step 7: Put the document of vector form into the SVM classifier for classification according to the training model.

Step 8: Output classification results. Calculate precision and recall rate.

(2) Sentiment polarity classification

The algorithm flow chart is shown as following.

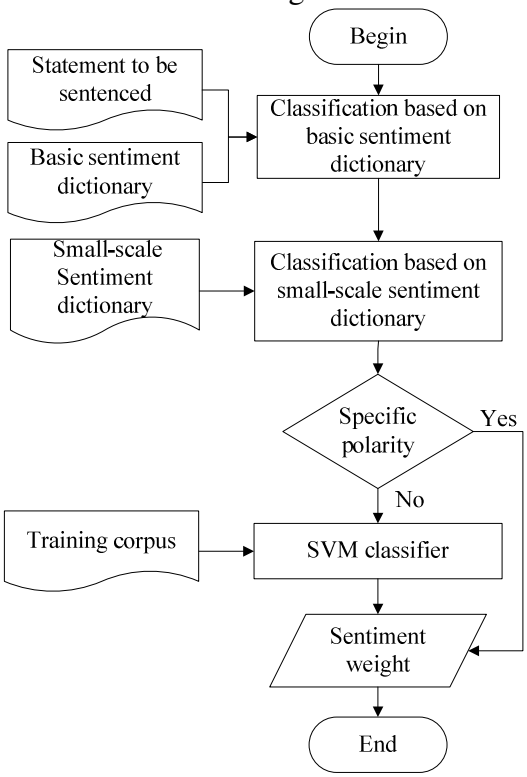

Fig.2. Flow chart of sentiment polarity classification

The core idea of sentiment polarity classification about statements is applying a variety of classification methods on test corpus, putting the higher accuracy algorithm on the top surface. The sentence that has already owned results of separation is outputted immediately. Statement that can't be classified in the layer classification algorithm should be pushed to the next layer for

classification. This paper combines sentiment dictionary algorithm and SVM machine learning algorithms together, which tries to take advantage of a variety of algorithms.

Step 1: Build basic sentiment dictionary throw integrating existing dictionary and constructing areas sentiment dictionary. Basic sentiment dictionary contains commendatory and derogatory dictionary.

Step 2: Treat statements into segmentation using existing segmentation software. Then extract basic sentimental words in statements and match the words in sentiment dictionary. Get its sentiment polarity and corresponding weights.

Step 3: In addition to sentiment words themselves, there are negative words, degree adverbs, turning words, interjections, punctuation, emoticons which influence sentiment tendency greatly. Construct all types of small-scale sentiment dictionary, marking sentimental words and its corresponding sentiment weight.

Step 4: Use small-scale sentiment dictionary to process context semantic information, and extract modifier word, emoticons appearing within a certain range of sentimental words. Calculate its sentiment weight based on constructed small-scale sentiment dictionary which contains modifiers, emoticons. At last, weight the value with result of Step2 and get final sentiment value.

Step 5: Determine sentence tendentiousness based on the calculated final sentiment value. Push the statement into next level of classification algorithms if sentiment tendency intensity of the statement is too weak to definite its tendentiousness.

Step 6: Adopt SVM classifier for the final classification about sentiment statements that all above algorithms can not determine its sentiment tendency.

Sentiment tendency weighted calculation method is introduced as follows:

Divide a text into n sentences named S_1, S_2, …,S_n , and then extract a sentimental word w_i.

(1) If a degree adverb or turning word w_a appears around w_i to qualify the sentimental word, weight of the sentimental word O_{w_i} is calculated by the following formula.

$$O_{w_i} = M_{w_a} \times S_{w_i} \tag{1}$$

Among it, M_{w_a} stands for the weight of degree adverbs or turning words, and S_{w_i} represents the weight of sentimental word w_i.

(2) If a negative word w_b appears around w_i to qualify the sentimental word, judge whether to invert the polarity of w_i according to number of negative words. Weight of the sentimental word O_{w_i} is calculated by the following formula.

$$O_{w_i} = M_{w_b} \times S_{w_i} \tag{2}$$

Among it, M_{w_b} stands for the comprehensive weight of negative words.

(3) When a emoticon w_e appears around w_i, put the sentiment weight of w_e to the weight calculation of w_i as following formula.

$$O_{w_i} = M_{w_e} \times S_{w_i} \tag{3}$$

Among it, M_{w_e} stands for the weight of the emoticon w_e.

(4) The statement S_i probably consists of k sentimental words named W_1, W_2, ...,W_k. So the weight of sentiment tendency about S_i is calculated by the below formula.

$$O_{s_i} = \sum_{i=1}^{k} O_{w_i} \tag{4}$$

(5) If a text d_i include n sentences, its final sentiment tendentious is computed by the following formula.

$$O_{d_i} = \sum_{i=1}^{n} O_{s_i} \tag{5}$$

$$O_{d_i}\begin{cases} > 0; d_i \text{ presents positive sentiment.} \\ = 0; d_i \text{ presents neutral sentiment.} \\ < 0; d_i \text{ presents negative sentiment.} \end{cases} . \quad (6)$$

Conclusion

This paper puts forward an approach of sentiment tendency analysis for comment texts, which mainly adopts the idea of layering. At first, the method uses SVM classification method to classify corpus into subjective and objective statements. And then we combine sentiment dictionary algorithm and SVM machine learning algorithms together to do sentiment polarity classification about subjective statements from the prior layer, obtaining author's sentiment tendency. Considering impacts of semantic information on sentiment calculation, the method makes full use of the modified relation of sentence structure, which makes the analysis process more scientific and reasonable. However, the disadvantage of this method is that inaccuracy is accumulated from one layer to the next layer. We will try our best to reduce the inaccuracy transformation in the future.

Keywords: Process Mining; Namesake Task; Repetitive Task; Complex Structure

Abstract. Process mining is helpful for deploying new business processes as well as auditing, analyzing and improving the already enacted ones. The business process system log often has a large number of the namesake task and repetitive task. The existing alpha algorithm of the mining algorithm cannot distinguish them very well. It leads to the results that the process mining often produce inaccurate flow model. In order to improve the accuracy of the process mining, the paper puts forward an improved method. The new method not only can dig the complex structure, such as circulation structure, free choice structure and so on, it still can dig the eponymous task and repeat task in the log.

Introduction

With the rapid development of information technology nowadays, workflow technologies have been widely used. Among them, enterprise modeling is an important field in workflow technology application. Process mining is an important method of Enterprise modeling. Research on process mining are mainly focused on mining the heuristic rules based on the binary sequence relationship which was recorded in the logs, and then extract the process model based on these rules. But the structures exist in actual workflow models have many complex structures which increase the difficulty of process mining, such as duplicate tasks, hidden tasks, implicit places, non-free-choices.

The scholars at home and abroad have done a lot of work in the process mining [1][2]. So far, experts have put forward many meaningful and understanding languages to definite the model. In the process mining, Agrawal firstly use the process mining algorithm applied to workflow management system. Initially, this algorithm requirements process does not exist circulation, the model dig out by the process illustrate by diagram which has direction but no circulation. But Agrawal disposed part of the circulation problem when he improved the algorithm. Herbst and others proposed another algorithm [7][8] based on the ADONIS language. This algorithm deal well with the structure which containing the same activity name in the process, and find simple circulation structure. But to finding hide structure it haven't realized. Aalst and Weijter posed α algorithm [10][11] that based on the extended Petri nets to find equivalent substitution with And-split, And-join structure. But it only uses for the relationship between each activity relationship. Thus, it cannot find the structures which need considering the global structure like NFC (no-free-choice) structure. And also it is helpless in two conditions that the same process contains the same activity name or complex circulation structures.

Paper [9] puts forward α algorithm in mining workflow model and proves it can label the model species accurately. Because α algorithm utilizes set to define the relationships between tasks. α algorithm regards the repetitive task as the same task when it judges the repetitive tasks, so it always dig out the error process model. Paper [3] puts forward a new algorithm which can dig out complex structure in logs such as invisible task, circulation structures and the uncertain parallel

choice structures. But because of this algorithm is on the basis of the α algorithm just improved, so it still can't solve the problem of namesake task and a repetitive task. Here will be proposed an improved method on the basis of the algorithm in paper [3] by which can not only solve the above problems but also improve the accuracy of the process mining.

Related Work

A task might appear in the same workflow model in many times. At this time, multiple tasks with the same name, this task is the repetitive task. In actual work, a repetitive task generally exists in the flow model. So, at first this paper gives a few necessary definitions. In order to ensure that the structures in the mining results weren't be lost by the loss of the log, so the log used here is completely. Therefore, the following are the completeness definition of log:

Definition l: set w is composed of task set T business process produces event logs, σ is task track product by business process execution once. $\sigma \in W$. W is completeness, iff:

(1) the task set for the business process consist T produces any event log W', there is $W' \in W$。

(2) For any$t \in T$, exist $\sigma \in W$ make$t \in \sigma$.

(3) For the event log W', if W' have σ'_1=…xy…, σ'_2=…xay…, σ'_3=…xaay…, and $a, x, y \in T$, then there must be$\sigma_1, \sigma_2, \sigma_3 \in W$and σ_1=…xy…, σ_2=…xay…, σ_3=…xaay….

Circulation task has been defined in [3]. The follow will definition repetitive task.

Definition 2: Set W is the event log produces by the business process consists of by the task set T. iff exit $\sigma \in W$, $\sigma=t_l \cdots t_i \cdots t_j \cdots t_m$, $t_i=t_j$, $t_i \notin Loop1(t_i)$and$t_i \notin Loop2(t_i)$, then says t_i for a repetitive task. The repetitive task t set recorded as D(t).

A repetitive task may appear in the sequence structure, parallel structure or choose structure, below Figure 1 (a) to (f) give a repetitive task appear of 6 combinations of structure.

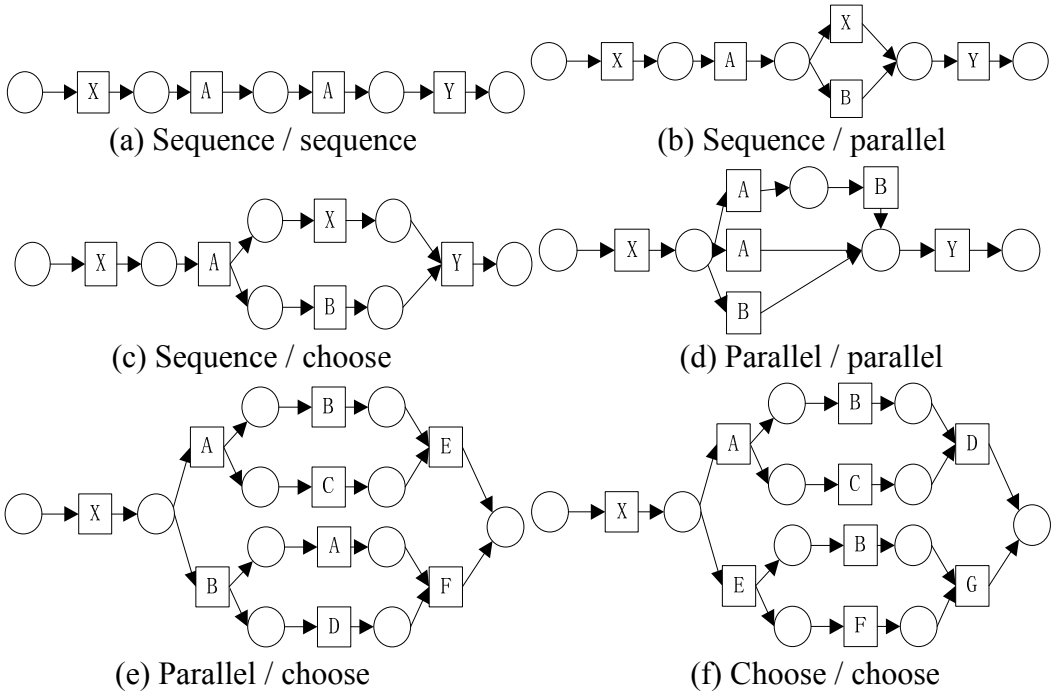

Fig.1. The sequence structure

Definition 3 (definition namesake task): Set W is the event log produces by the business process consists of by the task set T. Iff exit $\sigma_1, \sigma_2 \in W$, $\sigma_1=t_l \cdots t_i \cdots t_j \cdots t_m$, $\sigma_2=t_l \cdots t_i \cdots t_j \cdots t_m$,$i \in [1, m]$and $j \in [1, n]$, if t_i, t'_j generated by the same activity which in the same position in business process, Then t_i, t'_j are the same task. The repetitive task t set recorded as S(t).

Foundation Work

When business process contains circulation task and a repetitive task, a task will repeat many times in the produced event log. In order to determine the task of been repeated from circulation tasks, a repetitive task or the same tasks, need to justify the repetitive task.

Determine the same tasks and a repetitive task.

Definition 1: Set W is the event log produces by the business process consists of by the task set T.σ，$\sigma' \in W$，t，$t' \in T$，i，$j \in [1，n]$，if $t(\sigma,i) = t(\sigma',j)$then$\{t(\sigma,i),t',j)\} \in S(t)$.

This attribute is easy to prove.

Theorem 1: Set W is the event log produces by the business process consists of by the task set T. $\sigma \in W, t \in T$, $t \notin Loop2(t)$ and $len(\sigma)$ =n(n>1). If exit $i,j \in [i,n], i \neq j, t(\sigma,i) \neq t(\sigma,j)$, then$\{t(\sigma,i),t(\sigma',j)\} \in D(t)$.

Proof: Assuming$\{t(\sigma,i),t(\sigma,j)\} \in D(f)$. because $t(\sigma,i),t(\sigma,j) \notin Loop2(t)$, so$t(\sigma,i),t(\sigma,j) \in S(t)$, then there are $t(\sigma,i) = t(\sigma,j)$and i=j This is conflict with the known condition i≠j, $t(\sigma,i) \neq t(\sigma,j)$, so $\{t(\sigma,i),t(\sigma,j)\} \in D(t)$. End.

Theorem 1 had guaranteed the repetitive task in the same task path can be discovered.

Theorem 2: Set W is the event log produces by the business process consists of by the task set T. $\sigma,\sigma',\sigma'' \in W$. $A,A' \in sub(\sigma) \vee sub(\sigma)$.X, Y ∈ T, then

(1) if exit$A \parallel A'$, Also is$AA'\Theta(\sigma,[X,Y])$ and $A'A\Theta(\sigma',[X,Y])$, then

$\{A[XAA'Y],A[XA'AY]\} \in S(A)$; (1)

$\{A'[XAA'Y],A[XA'AY]\} \in S(A')$; (2)

$\{X[XAA'Y],X[XA'AY]\} \in S(S)$; (3)

$\{Y[XAA'Y],Y[XA'AY] \in S(S)$. (4)

(2) if exit$A \oplus A'$, also is $A\Theta(\sigma,[X,Y])$and $A'\Theta(\sigma,[X,Y])$, then

$A[XAY] \in S(A)$; (5)

$A'[XA'Y] \in S(A')$; (6)

$\{X[XAY],X[XA'Y]\} \in S(X)$; (7)

$\{Y[XAY],Y[XA'Y] \in S(Y)$. (8)

(3) if exit$A \propto A'$, also is $A\Theta(\sigma,[X,Y])$ and $AA'A\Theta(\sigma',[X,Y])$,then

$\{A[XAY],A[XAA'AY]\} \in S(A)$; (9)

$A'[XAA'AY] \in S(A')$; (10)

$\{X[XAY],X[XAA'AY]\} \in S(X)$; (11)

$\{Y[XAY],Y[XAA'AY]\} \in S(Y)$. (12)

(4) If exit$A\infty$, also is$\emptyset\Theta(\sigma,[X,Y])$, $A'\Theta(\sigma',[X,Y])$ and $AA\Theta(\sigma'',[X,Y])$, then

$\{A[XAY],A[XAAY]\} \in S(A)$; (13)

$\{X[XY],X[XAY],X[XAAY]\} \in S(X)$; (14)

$\{Y[XY],Y[XAY],Y[XAAY]\} \in S(Y)$. (15)

Proof (1): Because $\sigma = \cdots XAA'Y\cdots, \sigma' = \cdots XA'AY\cdots$, so $X > A, A > A', A' > Y, X > A', A' > A, A > Y$. Because $A \parallel A'$, so there are$X \to A, A' \to Y, X \to A', A \to Y$. use the improved algorithm can get work parameters N_P. Thus can get a conclusion that:

$\{A[XAA'Y],A[XA'AY]\} \in S(A)$; (16)

$\{A'[XAA'Y],A'[XA'AY]\} \in S(A')$; (17)

$\{X[XAA'Y\},X[XA'AY]\} \in S(X)$; (18)

$\{Y[XAA'Y],Y[XA'AY]\} \in S(Y)$. (19)

The proof (2)～(4) are similar with proof (1). End.

Theorem 3: Set W is the event log produces by the business process consists of by the task set T, $t \in T, \sigma,\sigma' \in W$. If the task t and t' in the task path exit relation $tRt'(R \in \{>,\parallel,\oplus,\propto,\infty\})$, in the task path σ' the task t and t' exit relation$R't'(R' \in \{>,\parallel,\oplus,\propto,\infty\})$ and R≠R', then

$\{t(\sigma,[tRt']),t(\sigma',[tR't'])\} \in D(t)$; (20)

$\{t'(\sigma',[tRt']),t'(\sigma',[tR't'])\} \in D(t)$. (21)

Proof: assuming $\{t(\sigma,[tRt']),t(\sigma',[tR't'])\} \notin D(t)(R \neq R')$ and $\{t'(\sigma,[tRt']),t'(\sigma',[tR't'])\} \notin D(t)(R \neq R')$, can get $\{t(\sigma,[tRt']),t(\sigma',[tR't'])\} \in S(t)$, $\{t'(\sigma,[tRt']),t'(\sigma',[tR't'])\} \in S(t)$, use the theorem 2 can get R=R', this is conflict with R≠R' , so we can draw a conclusion that:

$$\{t(\sigma,[tRt]),t(\sigma',[tR't'])\} \in D(t); \quad (22)$$

$$\{t'(\sigma,[tRt]),t'(\sigma',[tR't'])\} \in D(t). \quad (23)$$

Proof end.

The circular task and repetitive task in business process are extremely easy to confusion, but the two kinds of structure are really and respectively exit. In order to dig out the correct flow model, we must criterion them carefully.

Algorithm

Here, process mining is divided into preprocessing, processing and post processing. The pretreatment stage basically filters a repetitive task and namesake task. The processing stage mainly analysis the complex structure, such as circulation structure, the unfreedom parallel choice, invisible task and so on, and dig out the preliminary workflow model. The later stage of processing is main reduction the task's original name which renamed and change the connection relationship of connection library in relations sets.

Based on the attribute 1 and theorem front 1-3, and combined with the improved algorithm in literatures [3], this paper puts forward another kind of the improved algorithm to dig the repetitive task. T is the task set, W is the workflow log on task T. σ and the partial order relation between tasks reference the definition in literature [3]. Specific algorithm is described below.

Step 1: filter the repetitive task and the namesake task

According to the workflow log W calculated all appeared task in W composition set D(t).

Using attribute 1 and theorem 1 ~ theorem 3, identify the namesake tasks and the repetitive task, and put the repetitive task T into D(t). Rename the tasks by adding subscript in D(t),Updated the log after rename and get new event log T_{log}.

Step 2: Mining the T_{log} use the new mining algorithm in literature [3]. The library of ultimately result set named W^{DT}.

1) $LIL = \{t \in T_{log} | \exists \sigma = e_1, e_2, \dots, e_j, \dots, e_n \in W[e_i \cdot task = e_j \cdot task = e_k \cdot task = t \wedge l = k+1 = i+2 = j+3]\}$

2) $T' = T_W | L1L, L2L = \Phi;\ F_{L1L} = 0.$

3) $For\ each\ t \in L1L, do$

$A = \{a \in T' | a >_w t\};\ B = \{b \in T' | t >_w b\};$

$if\ \forall a_1 \in A, b_1 \in B\ \ a_1 >_w b_1 \Rightarrow$

$F_{L1L:} = F_{L1L} \cup \{(t, p(A|B, B|A)), (p(A|B, B|(L1L: = L1L - 1) \wedge (L2L = L2L \cup t)$

$\wedge F_{L1L:} = F_{L1L} \cup \{(tjump, p(A,t)), (p(t,B), tkump)\}$

4) $W^{-L1L} = \Phi$

5) $For\ each\ \sigma \in W, do\ \sigma' = \sigma$

$For\ each\ t \in L1L, do\ \sigma' = remove\ Task\ (\sigma', t), TW = TW - t;$

$For\ each\ t \in L2L, do\ \sigma' = remove\ Task\ (\sigma', t, 1); W^{-L1L} = W^{-L1L} \cup \sigma'.$

6) $W = W^{-L1L}$

7) $X_W = \{< ps, ss, op > | ps \subseteq T_W \wedge ss \subseteq T_W \wedge op \in op\ \wedge\ \forall a \in ps\ \ \forall b \in ss\ \ a \rightarrow_w b\ \ op = default\ \}.$

8) $D_S = \left\{ \left(t_{(P_{in};P_{out})}; t_{(P'_{in};P'_{out})} \right) \middle| (P_{in}; P_{out}); (P'_{in}; P'_{out}) \in Y_I \cup Y' \wedge P_{out} \cap P'_{in} \neq \Phi \right\} \cup \{(a, t_{(P_{in};P_{out})}) | (P_{in}; P_{out}) \in Y_I \cup Y' \wedge \exists (A,X) \in P_{in}: a \in A\} \cup \{(t_{(P_{in};P_{out})}; b) | (P_{in}; P_{out}) \in Y_I \cup Y' \wedge \exists (Y,B) \in P_{out}: b \in B\}$

9) $D_P = \left\{ \left(t_{(P_{in};P_{out})}; t_{(P'_{in};P'_{out})} \right) \middle| (P_{in}; P_{out});\ \ (P'_{in}; P'_{out}) \in Y_I \cup Y' \wedge \forall (A,X) \in P_{in};\ \ (A'; X') \in P'_{in}: \exists a \in A;\ a' \in A';\ x \in X;\ x' \in X': a \| W\ a' \vee x \| w x' \right\} \cup \{(t; t_{(P_{in};P_{out})}) | t \in T_W \wedge (P_{in}; P_{out}) \in Y_I \cup Y' \wedge \forall (A,X) \in P_{in};\ \exists a \in A;\ x \in X;\ a \| W\ \ t \vee x \| w\ t\}$

10) $T_W = T_W \cup \{t_{(Pin;Pout}|(P_{in};P_{out}) \in Y_I \cup Y_1'\}$

11) $(W^{DT}) = (T_W;T_I;T_O;D_S;D_P)$.

Specific algorithm introduces reference the algorithm [3] description.

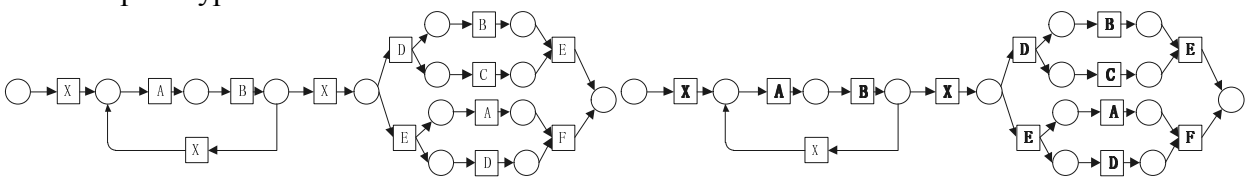
Step 3:post-processing

1) Take the repetitive task in T_W which renamed to their original names and then save it into T_W.
2) Take the arc which is relevant with the rename repetitive task in D_P connection to the original names task and then save it into D_P.
3) Set $N = (W^{DT}) = (T_W;T_I;T_O;D_S;D_P)$.

Algorithm end.

Experiment

The algorithm used in experiment program is written in C language, it realizes the Experimental prototype include the algorithm in [3]. In the experiment we use CPN Tools (color petri net tools) establishes five workflow models which contains repetitive task [12][13]. Firstly we randomly generated a workflow log which contains 1,000 event tracks for each model, and then analysis the log file. The following Figure 2 (a) and (b) give the compare which using experimental prototype and using an improved algorithm for mining between the results of the model. Owing to space restrictions only give one group of model contrast here. Through the experiment we can know that the improvement algorithm can recognition repetitive task, and get workflow model which is the same with prototype.



(a) Prototype model N2 (b) The mining model

Fig.2. Model contrast

Experimental results show that the improved algorithm can effectively distinguish and mining the namesake task and repetitive task. According to the improved algorithm written the ProM plug-in, this paper selects five groups of examples log as experiment logs. Running the improved mining algorithm get experimental results shows as following Figure 3.

The Experiments show that the improved algorithms can effective mining invisible task, circular structure and unfreedom choice structure.

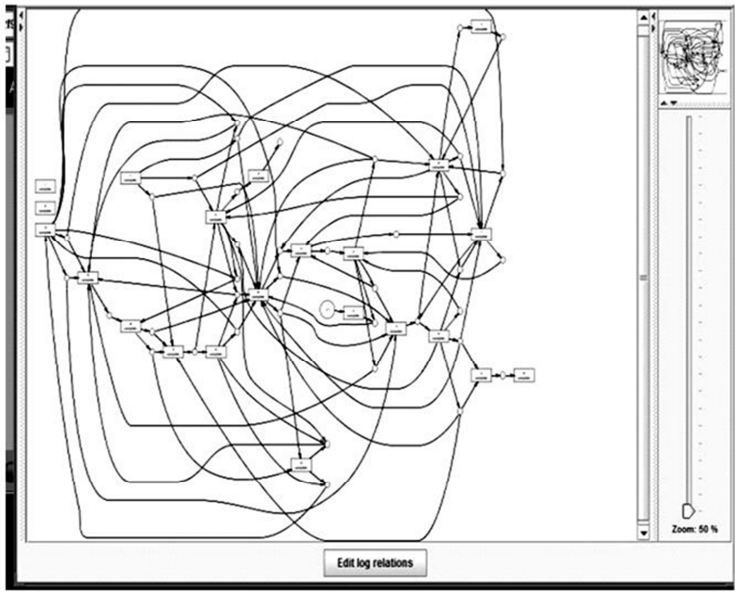


Fig.3. Mining result

Conclusion

The improved algorithm overcomes the mining limitation of α algorithm. Analysis from the experiment, the improvement in this paper can effective mining the namesake task, repetitive task, circulation structure, unfreedom choice structure and so on, which structure exit in system log. But the algorithm does the experiment with the completed log. The experiment does not consider the influence of the noise, and the mining accuracy of complex structures which have some reduce.

Keywords: process mining; log; algorithm

Abstract. Process mining is helpful for deploying new business processes as well as auditing, analyzing and improving the already enacted ones. This paper summarizes the scholars' main studies in workflow mining, introduces the modeling process of two different kinds of mining algorithms in detail, compares and analyzes their performances, and explains the modeling process with an actual example.

Introduction

Workflow is a kind of business process that can be fully or partially automated implemented [1], which realize the automated integration and business process management by defining the relationships between activities. Workflow modeling is usually defined by the enterprise workflow modeler based on documents, or participants in the process models consultation, which is simple, intuitive, easy, and is the primary means of current modeling. However, the modeling way was very susceptible to the individual ability and the subjective experience of the participants, which makes the model only express the process "should" look, rather than its "real" look. In the meantime, the modeling method which relies solely on the modeler not only inefficient but also has high cost.

Based on this regard, some experts propose a new workflow modeling method- work flow log based automation process modeling known as workflow mining. This modeling approach uses data mining thinking through the analysis of business interaction records, i.e., workflow logs, and then automated derive the enterprise workflow model through mining algorithms. Most companies have established ERP, CRM, SCM and WFMS systems in real life. With the implementation of these business workflow systems, the log records provide a large data base for the enterprise workflow mining. The model established by such modeling methods can reflect the actual enterprise business execution processes, and the modeling process is automated implemented, which not only reduces the impact of modeler and participants, but also can improve the modeling efficiency.

Related works

"Workflow mining" first appeared in the field of software engineering, proposed by USA Joanthan E. Cook in 1995, a professor of computer science at New Mexico State University [2]. In 1998, Rakesh Agrawal of IBM Almaden Research Center in the United States applies it to enterprise workflow modeling for the first time [3].

Joanthan E.Cook and Alexander Wolf designed three kinds of workflow mining method in literature [2], in which KTail and Markovian approach is practicality stronger than RNet. But these three methods all use finite state machine (FSM) model as their formal description, which restricted its ability that can only represents the sequential structure workflow model because the FSM describe limitation.

Rakesh Agrawal et al. designed two workflow mining algorithms and use “directed graph” to describe workflow model [3]. Both algorithms can be deduced from the workflow model with causal and cycle relationship, but difficult to handle process with synchronous and selection relationships, i.e., the And-join/split and OR-join/split structure.

Gudio Schimm designed a workflow mining algorithm that can be used to deal with a hierarchical structure [4], and developed its mining tool (Process Minner).But the algorithm difficult to deduce the workflow business process models with cyclic structures.

Joachinm Herbst and Karagiannis applied the inductive method in workflow mining [5][6]. But the method in literature [5] can only deduce sequence workflow structure. The mining method in literature [6][7] considered the problems of process synchronization, but it is difficult to deal with the selection and circulation relationships. In addition, because the workflow model of these two mining methods can only use “random activity diagram”, which also has their limitations.

The mining algorithms Aalst designed can mainly divide into two categories: formal and non-formal mining algorithms [8][9], and both use WF-net to represent the workflow mining results. Between these two methods, the formal algorithm requires complete workflow logs without noise, and can only deduce reasonable workflow structure model which cannot handle non-freedom choice structure; the non-formal algorithm has no specific workflow log requirements, but it is difficult to deal with short- cycle workflow structure.

Definitions

In this part, the basic workflow concepts that used in the process mining are been defined and explained.

Definition 1(workflow log): Let T be the set of activities. $\sigma \in T^*$is called the workflow traces. $W \in P(T^*)$ is the workflow log, which $P(T^*)$ is theset of T^*.

Definition 2(Petri nets): Petri net PN is a triple (P, T, F):

- P is a finite set of places;
- T is a finite set of transitions,$P \cap |\cdot t| = 1$;
- $F(P \times T) \cup (T \times P)$ is a set of arcs (or flow relations).

Definition 3(WF-net): Petri net PN is a workflow net N where:

1) PN has two special places: I and o. i is a start place, i.e., i = Φ; place o is the end place, i.e., $o \cdot = \Phi$.

2) Each node $x \in P \cup T$is on one path from i to o.

Definition 4 (structured workflow net SWF-net): workflow net N = (P, T, F) is a SWF-net where:

1) $\forall p \in P, t \in T$, there is $(p, t) \in F$, then $|\cdot t| = 1$ when $|p \cdot| = 1$;

2) $\forall p \in P, t \in T$, there is $(p, t) \in F$, then $|\cdot p| = 1$ when $|t \cdot| > 1$;

3) There are no hidden places.

Definition 5 (basic relationships between activities): Let W be the workflow log, the activity set T, there is $W \in P(T^*)$, assume$a, b \in T$:

1) a and b has the direct sequence relationship $a >_w b$ where: $\exists \sigma = t_1 t_2 \dots t_{n-1} i \in \{1,2, \dots n\}, \sigma \in W, and\ t_i = a, t_{i-1} = b$

2) a and b has the casual relationship $a\#_w b$ where: $a \not> _w b\ and\ b \not> _w a$;

3) a and b has the parallel relationship $a //_w b$ where: $a >_w b\ and\ b >_w a$;

Define 6 (∈, first, last): Let T be the active set, $a \in T$ and $\sigma = a_1 a_2 \dots a_n \in T^*$ is the workflow track of length n.

1) $a \in \sigma$where:$a \in \{a_1 a_2 \dots a_n\}$;

2) $\text{first}(\sigma) = a_1$

3) $\text{last}(\sigma) = a_n$

Definition 7 (complete workflow log): Let N = (P, T, F) is reasonable WF-net:

1) W is the workflow log of N where: $W \in P(T^*)$ and Each group workflow trace$\sigma \in W$ is a sequence that begins from the initial state [i] to the end state [o], i.e., $(N,[i])[\sigma > (N,[o])$

2) W is a complete workflow log of N where:

a) For any workflow log W' of N, there is $>_{w'} \subseteq >_{w}$;

b) $\forall t \in T, \exists \sigma \in W,$ there is $t \in \sigma$.

Algorithms and Compares

The current workflow mining algorithms can be divided into two categories: formal mining algorithms mining algorithms and heuristics mining. Formal algorithms derive the workflow model from the workflow logs through formalization method. The heuristic mining algorithms first derive the basic logical rules between activities based on the heuristic rules, and then build the workflow model.

A. Formal mining algorithm - α algorithm

α algorithm recognizes the basic relationships between workflow log activity by formal methods, and then establish the workflow model based on the relationships. The specific algorithm is as follows:

Let W be the workflow log, T is the activity set, α(W):

(1)$T_W = \{t \in T | \exists_{\sigma \in W} t \in \sigma\}$

(2)$T_I = \{t \in T | \exists_{\sigma \in W} t \in first(\sigma)\}$

(3)$T_O = \{t \in T | \exists_{\sigma \in W} t \in last(\sigma)\}$

(4)$X_W = \{(A,B) | A \in T_W \wedge B \in T_W \wedge \forall_{a \in A, b \in B} a \rightarrow_W b \wedge_{a1,a2} a1 \#_W a2 \wedge_{b1,b2} b1 \#_W b2\}$

(5)$Y_W = \{(A,B) \in X_W | \forall_{(A',B' \in X_W)} A \subseteq A' \wedge B \subseteq B' \Rightarrow (A,B) = (A',B')\}$

(6)$P_W = \{p(A,B) | (A,B) \in Y_W\} \cup \{i_W, o_W\}$

(7)$F_W = \{(a, p(A,B)) | (A,B) \in Y_W \wedge a \in A\} \cup \{(p(A,B), b) | (A,B) \in Y_W \wedge b \in B\} \cup \{(i_W, t) | t \in T_I\} \cup \{(t, o_W | t \in T_O)\}$

(8)$\alpha(W) = \{T_W, P_W, F_W\}$

The specific steps of α algorithm are as follows:

Step 1 establishes the current log collection T_w; step 2 and step 3establish the input transition set T_i and output transition set T_o; step 4derivesthe transition set X_w with causal relationship, the transition in set A has causal relationship with the transition in set B, but the transition within A and B has no causal relationship. We can discover AND(OR)-Split/Join structure by limiting the set of A and B; step 5 redefines X_w by establish the largest collection of A and B; step 6 is used to establish the places of transitions; step 7 establishes the flow relationship between the place and the transition. Step1 to step7can derive the process model from the workflow log, and represents it by WF-net.

This formal mining algorithm is simple and easy to understand, but has certain limitations in the application as follows:

(1) The algorithm requires a complete workflow log, otherwise the model been derived may lost some relationships between the activities. Obviously, this formal mining algorithm is only suitable for simple structure and complete workflow log process.

(2) The log noise will affect the derivation of the basic relationship between activities which makes the algorithm has lower robustness of noise.

(3) The algorithm is difficult to identify the one-step and two-step cycle structure, and can only create model with SWF-net. The adaptability of the algorithm is not strong.

B. Heuristic Algorithm

Heuristic mining method derives the basic relationship between activities by heuristic rules from the workflow log is divided into three steps:

(1) Create dependency/frequency table (dependency/frequency table, D/F table) (As shown in Table 1)

For the activity a and activity b, we can have the following information from the log:

1) the appear frequency of activity a and b, i.e., #a, #b; 2) the frequency that b directly before a, i.e., #b<#a; 3) the frequency that b directly inherit a, i.e., #a>#b; 4) the total frequency that b before a, i.e., #b<<<#a; 5) the total frequency that a before b, i.e., #a>>>#b; 6) the dependencies between a and b, i.e., #a→#b.

Table 1 The D/F table from b to a

#a	#b	#a>#b	#b<#a	#a>>>#b	#b<<<#a	#a→#b

(2) Derive the basic relationship between activities according to the D/F table.

Define the heuristic rules, and derive the basic relationships based on the D/F table ($a \rightarrow_w b$, $a \#_w b$, $a \,//\, _w b$).

The heuristic rules of causal relationship are as follows:

IF $(\#a \rightarrow b \geq N)$ *AND* $(\#b < \#a \leq \theta)$ *AND* $(\#a > \#b \geq \theta)$

THEN $a \rightarrow_w b$

N is the noise factor, the default value N = 0.05, the N increases with the increasing of log noise. The threshold $\theta = (1 + \mathrm{ROUND}(\mathrm{N} \times \#\mathrm{L})) / (\#\mathrm{T})$.

Which tracks the total number of rows workflow # L on behalf of the log, # T represents the total number of activities.

(3) After the basic relationship between activities been clearly discovered, then create the workflow model based on α algorithm.

Heuristic algorithm improves the application limitations of α algorithm. First, the parameters N and θ can effectively handle the log noise, i.e., the algorithm is robust. Second, since the algorithm is deriving the basic activity relationships based on the heuristic rules, so the integrity of the log is not strictly required. But because it is often difficult to accurately setting the value of θ and N before digging, so the mining quality maybe affected by different θ and N.

C. Comparative analysis of algorithms

The previous sections respectively introduced two types of workflow mining algorithms, which have their own application conditions and domains. Table 2 compares and analyzes the two algorithms from different angles.

Table 2 The comparative analysis of the α algorithm and heuristic algorithm

	application condition	WF-net structures can be mined	robustness for noise	Process model structure	advantage	disadvantage
αalgorithm	complete log with no noise	SWF-net(except one-step cycle and two-step cycle)	low	Figure	Simple, easy to understand, high operability	Unsuitable for complex workflow Process structure
Heuristic algorithm	/	SWF-net and most WF-net	high	Figure	Suitable for mining complex workflow process	The values of N and θ are not easy to determine

Case study

The workflow log (assuming that the log is complete and without noise) is shown in Table 3, which contains five workflow instance case1-case5. We use α algorithm to establish the workflow model.

Table 3 Workflow log

case	activity	case	activity	case	activity	case	activity
Case1	A	Case1	C	Case5	E	Case4	B
Case2	A	Case2	C	Case4	C	Case5	F
Case3	A	Case4	A	Case1	D	Case4	D
Case3	B	Case2	B	Case3	C		
Case1	B	Case2	D	Case3	D		

(1) Definite the basic relationships between the activities.

There are five workflow cases in the Log:

σ_1 = {A, B, C, D},

σ_2 = {A, C, B, D},

σ_3 = {A, B, C, D},

σ_4 = {A, C, B, D},

σ_5 = {A, B, C, D, E}.

By definition 5 we can have:

a) Direct relationship:$A >_W B, B >_W C,\ C >_W D,\ A >_W C,\ B >_W D,\ C >_W B,\ E >_W F$

b) Causal relationship: $A \rightarrow_W B,\ C \rightarrow_W D,\ A \rightarrow_W C,\ B \rightarrow_W D,\ E \rightarrow_W F$

c) Parallel relationship: $B||_W C,\ C||_W B$

(2) Use α algorithm to mine the process.

a) T_w= {A, B, C, D, E, F};

b) T_i= {A, E};

c) T_o= {D, F};

d) X_w= {(A, B) (C, D) (A, C) (B, D) (B, F)};

e) Y_w= X_w;

f) P_w= {p(A, B), p(C, D), p(A, C), p(B, D), p(E, F)} ∪ {i_w, o_w};

g) F_w= {(A, p(A, B)), (p(A, B), B), (C, p(C, D)), (p(C, D), D), (A, p(A, C)), (p(A, C), C), (B, p(B, D)), (p(B, D), D), (E, p(E, F)), (p(E, F), F), (i_w, A) (i_w, E) (D, o_w), (F, o_w)};

h) α(W)= {T_w , P_w , F_w};

(3) The process model describes with WF-net is shown in Figure 1.

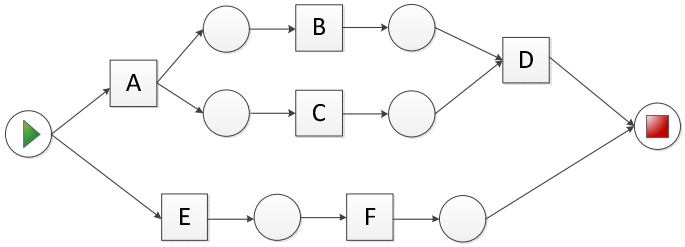

Fig.1.TheWF-net model of the process

Conclusion

This paper summarizes the status of the workflow mining technology research, detailing the two different types of mining algorithms -α algorithm and heuristic algorithm and its comparative analysis. Then in the following chapters, this paper points out their respective use conditions and the advantages and disadvantages, and explains the mining steps of αalgorithm with an example.

Keywords: Cloud Computing; P2P; Resource Management

Abstract. The technology of cloud computing has become a hot issue of research in the service of network in recent years. Cloud computing platform provide computing and storage services to customers. And it has been widely applied in e-business, e-education and etc.. While Cloud systems are usually hosted in large datacenters which may become a bottleneck to the system. In this paper we describe the design of a double-layer P2P model based on cloud computing. In the model, user nodes grouped into clusters form the Extended Cloud layer, and transfer file to each other without participation of the Core Cloud layer. The new model has better scalability and efficiency.

Introduction

Cloud computing is an extension of parallel computing, distributed computing and grid computing[1]. It has been one of the hottest issues of research. Major players of the IT industry have increasingly concentrated resources on Cloud schemes[2], such as the cloud computing platform and supporting apps from Google, the Blue Cloud platform from IBM[3][4], and the Elastic Compute Cloud (EC2) from Amazon[5][6]. And on such issues the academia is making progress in parallel. Google File System (GFS) [7][8]as a typical dynamic-content managing cloud is designed specifically for the intensifying demand of data processing by Google. A master server deployed to manage the information of all servers and to respond the users' inquiries, which represents a centralized index structure shared by many cloud computing systems, may become a bottleneck to the system extensibility. Researchers seeking counteract proposed to introduce in the P2P technology by substituting the master server of a GFS with a DHT to organize the servers directly[9], or by replacing the single master server of a GFS with a cluster of major servers[10], or by connecting individual components of the cloud computing platform via P2P technology[11]. However, all these P2P-based modifications confine their effort in optimizing the internal structure of the cloud computing platform, instead of mobilizing the equivalent features of the P2P technology.

This paper presents a P2P resource management model based on cloud computing, completed by an Extended Cloud structure derived from a Core Cloud from the service provider, with part of the Core Cloud load transferred to the Extended Cloud, in order to relieve the load of the core server, to improve the service quality of the Core Cloud, and to reduce the system cost.

Resourse Management Model

The proposed resource management model is a double-layer structure, as shown in Figure1. With the lower layer of a Core Cloud from the service provider, and the upper layer of an unstably-gathered Extended Cloud composed by users' computers. The Extended Cloud transfers the resources by transferring resources directly, grouping user nodes into clusters via the self-organization, and providing the low-cost content management. A user node requested resource will receive the replica node list from Core Cloud, and then communicate with the corresponding replica node in the Extended Cloud to transfer the file. User nodes communicate inside the Core Cloud, and release the load of Core Cloud.

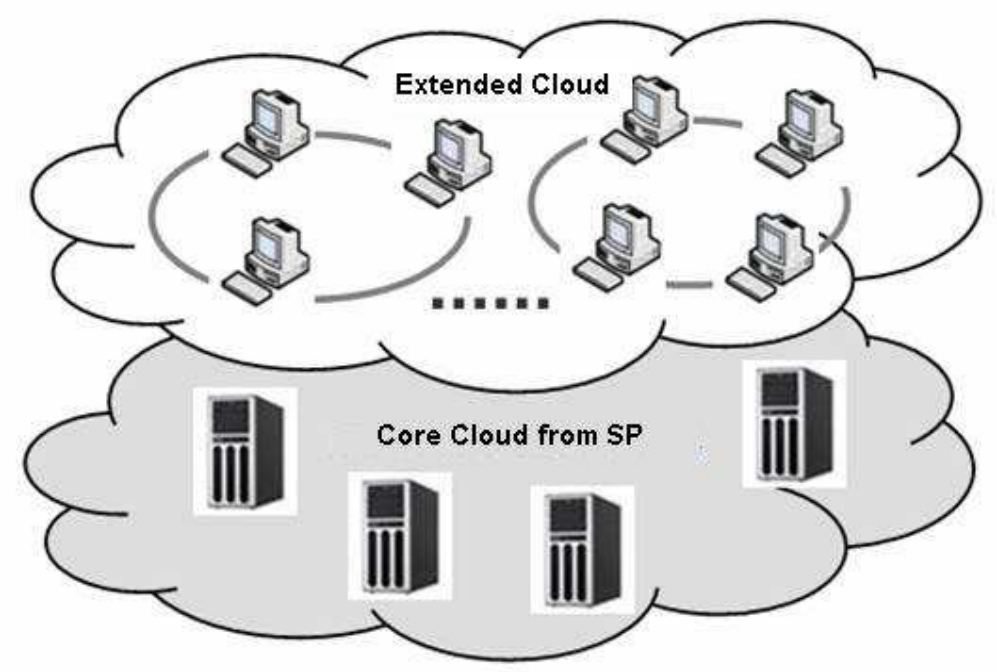

Fig.1. Resource management model

In the Extended Cloud, user nodes are grouped into clusters according to their communication condition. In order to consider Extended Cloud connectivity between the nodes, user nodes are grouped into clusters according to the latency of real world. We thus choose to use network latency because latency is often a direct indicator of the performance seen by end-host nodes and can be easily measured in a light-weight, end-to-end and non-intrusive manner.

We need M well-known landmark machines [12] to spread across the Internet. A user node measures its distance, i.e. round-trip-time, to this set of known landmarks and orders them by distance. This scheme is simple, requiring little support from the infrastructure. The only infrastructure requested is a small number (internet trace data indicates that 8-12 machines should suffice for the current scale of the internet) of relatively stable landmark machines. Little work is requested of these landmark machines – they need only echo "ping" messages – and landmarks could in fact be unsuspecting participants in the network. Landmarks neither actively initiate measurements nor gather or disseminate measurement information. Binning is scalable because nodes independently discover their bins without communicating or coordinating with other application nodes.

We constructs M clusters based on these landmarks and names them by landmarks' number, called CID. All nodes measure their round-trip-time (RTT) to each of these landmarks and initialize the value of CID according to Theorem 1.

Theorem 1: Let L={l0, l1, …lm-1} be the set of M landmarks, then a node A creates an ordering La on L. For example, i appears before j in La if RTT (A, li)<RTT (A, lj) or RTT (A, li)=RTT (A, lj) and li<lj. Node A initializes the value of A.CID using the first landmark in La.

Thus, based on its delay measurements to the different landmarks, every node has an associated ordering of landmarks and CID. User nodes that have the same CID are grouped into one cluster.

Note that with the above cluster scheme, node only needs to discover the distance between itself and the landmarks and can measure these distances itself. Nodes need not know the distance of other nodes from the landmarks. Also, cluster scheme is robust to the failure of one or more landmark nodes. In the case of landmark failures and performance degraded, new nodes will substitute for the old ones. And the corresponding clusters remain unchanged.

In the Core Cloud, each resource maintains a replica node list. The number of the replica nodes of each resource is determined by the intensity of resource inquiry (i.e. the frequency of inquiry for a certain resource), which means the more intensive the resource is requested, the more replica nodes will be attributed accordingly. When a node send request to the Core Cloud, the server will verify the node at first, and then answer the request with a replica node list. Then the Core Cloud

will verify the credibility of the node and the cluster where the node is located, and determine whether to designate such node as a new replica node according to the number of replicas for the requested resource. Once the credibility and the designation are confirmed, the information will be written in the replica node list of the resource. The replica nodes should be distributed into different clusters, with individual nodes available to be added or deleted according to the dynamic intensity of inquiry.

The user node receiving the replica node list will request the node in the same cluster, because the communication is more efficient among nodes in the same cluster. If all replica nodes are invalid, the user node will acquire the information directly from the Core Cloud.

Self-organized Mechanism

In a dynamic network, nodes can join (or leave) at any time. As shown in Figure 2, a new user node firstly obtains its CID by measuring RTT to each of landmarks, then send request to the Core Cloud including file's message, cluster number, and node's credit message. After received replica node list from the Core Cloud, user node should check whether there is node in the same cluster, and then send a request to it. If not, user node will request to the node in the neighborhood cluster. Then download the files from the replica node directly. If all nodes on the list are failure, it will send a notice to the server, and download from Core Cloud directly. Finally, the node checks whether it has been chosen as a replica node by server and save the message.

Nodes in the network may fail or depart without warning. If it is a replica node，it should issue a departure request into the system before its departure. The Core Cloud will update the replica node list, and then choose a new one. The absence of the non-replica nodes has no impact to the network, thus no status update is requested from such nodes.

In the real network, nodes change dynamically. The system needs to deal with nodes joining the system concurrently and the nodes that fail or leave voluntarily. The replica nodes in the Extended Cloud will regularly update their status to the Core Cloud. Any replica node failed to update its status for 3 cycles will be deleted.

```
// node N joins the network
N.join ( )
    //compute CID by measuring their RTT
    CID = N.find_cluster_num(N);
    //send a source request to Core Cloud
    //receive the replica list of the source
    R_List = N.send_request(SERVER);
    //if there are any available nodes
    //then send a load request to the node
    //and download the resource
    if (R_List is not NULL)
        CN=N.choose_node(R_List)
        N. load_request(CN)
    //if all the nodes on the list are failure
    // then request to download from Core Cloud directly
    else
        N.load_request(SERVER)
    // checks whether it has been chosen as a replica node
    RE=N.replica_node(CID,CM)
    if (RE) N.update_info()
```

Fig.2. Pseudo code for the node join

Performance Analysis

The resource management model presented in this paper is superior for:

Better Balanced Load: Unlike the traditional Cloud Computing-based models, this model separates the file replicas among the nodes of the Extended Cloud, in which the user node works as

both the client and the server of the resources without participant of Core Cloud, and significantly relieves the load of the Core Cloud.

Better Efficient File Transmission: The nodes in Extended Cloud are clustered by the landmarks, and choose the node in the same cluster for file transmission, which helps improve the transmission speed and avoid the bottleneck nodes.

Better Robustness: The file information is stored in the Core Cloud server and multiple replica nodes in the Extended Cloud. The number of the replicas is adjusted according to the inquiry intensity of the resource, by which the risk of single point failure is circumvented.

Conclusion

This paper presents a P2P resource management model based on cloud computing. It utilize the resources of user nodes by grouping such nodes into Extended Cloud, which is above the traditional Core Cloud. The Extended Cloud shares the file transmission load of the Core Cloud and maintains the efficient transmission through the clusters, and further reduces risk of transmission bottleneck and single point failure.

Architecture Research and Design of Cloud Computing Service Based on REST

Kun HUANG

Computer science and Technology Specialty of Sichuan TOP Vocational Institute, Chengdu 611743, China

e-mail: 83100024@qq.com

Keywords: architecture; cloud computing; REST;WASL; REST-style

Abstract. Cloud computing deployment model has: IAAS, PAAS, SAAS, and they can provide calls for the clients by web services. REST-style cloud computing architecture represents resource by the URI, and operates resources by standard HTTP methods GET, PUT, POST, DELETE, etc. In this paper, the e-city website as example, using REST methods to architect website, logistics, customer, the pay bank. The architecture fully reflects the REST architectural style is simple and convenient. But REST flaw is that the limited transaction-oriented processing capabilities. In order to solve this problem, WASL (Web Application Description Language) is used to describe the REST API.

Cloud Computing Architecture

Cloud computing is not a single technology, nor is it a combination of all kinds of technology; its core philosophy is to achieve on-demand services. It is a service that enables users to get required infrastructure, platform, application and other resources by the method to expanse easily, in accordance with their needs by network. Cloud computing architecture is shown in Figure 1:

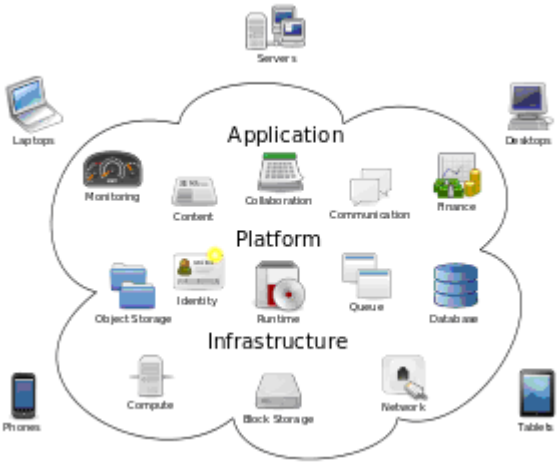

Fig. 1. Cloud computing architecture

Cloud computing services have three levels: IAAS (Infrastructure as a Service), PAAS (platform as a service), and SAAS (software as a service). Service is the foundation for cloud computing.

Main Solutions of Cloud Computing Services

In the cloud computing service architecture, usually three ways to provide services to clients. XML-RPC: XML (Extensile Markup Language) Remote Procedure Call Protocol; SOAP: Simple Object Access Protocol; REST: Representational State Transition.

XML-RPC: a remote procedure call (remote procedure call, RPC) protocol for distributed computing, the function package will be called by XML and use the HTTP protocol as a transport mechanism. Later, because the new features constantly being introduced, this standard slowly evolved into SOAP protocol today.

SOAP (Simple Object Access Protocol) is a standardized communication specification, SOAP based on HTTP protocol; put REQUEST parameters in written XML into HTTP BODY, and submit them to web service server to process; and then the results are written in XML as a response back to the client. In order to make that the client and WEB SERVICE can correspond with each other, you can use WSDL (Web Services Description Language) as the description file to describe this means of communication. SOAP has the ability to tie the complex objects serialized into XML. SOAP requires a series of complicated encapsulation; Even so, SOAP still can not reach the consistency of the interface, different vendors have their own interface.

REST (Representational State Transfer), use standard HTTP methods that is used by web service (GET/PUT/POST/DELETE), abstract all the web service as resources, REST observe the entire network from the perspective of resources, and all the resources determined by the URI, and the client application to get the characterization of resources through URI.

REST constraints

(1) Client / server mode: All Web services are required to meet this constraint.

(2) Stateless. The HTTP protocol is stateless.

(3) Cached response capabilities: for example, when a client requests information, if this information does not change the product within a day in the past, then you can find information on this product in a reverse proxy, the information is presented in cache and is returned directly cached statements, omitting the service execution.

(4) Uniform HTTP interface. REST HTTP specification must be strictly in accordance with the method to use the service. Thus, a POST to perform all rely on logic operation is not REST-style API.

Architecture Instance

REST architecture style, URI represents the resource, so order is a resource. GET can execute query an order; PUT can created an order; POST can modify an order; DELETE can delete an order, as shown in Figure 2 .

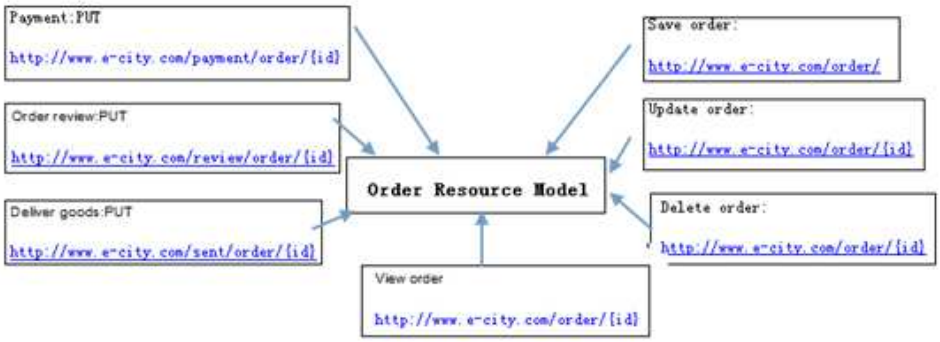

Fig. 2. Orders resource model

The architecture is designed to integrate the three systems, namely e-city reception sites, e-city background is ERP systems responsible for warehousing, shipping and logistics into , and ERP system of outsourcing logistics. Three systems each have their own processing, end to end processing of the entire order is complete together by three systems.

When we submit an order in e-city, a message is sent back to the background ERP system; the news triggered a flow of goods out of the warehousing and on the meanwhile a flow of parcel delivery in the logistics company. When we complete to pay to the distribution staff, the shopping process has ended for our customers. The distribution staff backs their money, a message is sent back to the backstage ERP, logistics and parcel delivery company's process ends, and this e-city order processing is complete.

In these interactions, the most important thing is that we achieved “hypermedia as the engine of application state” which is called by REST community through workflow. W Workflow responsibility is to manage the lifecycle of orders, At different stages of their life cycle, we have different players, different operating authority for the order.

More simply, URI represents the state transition in the state machine. The <squence>, <activity> and <xor> tabs allows clients to operate the state machine transfers by the way to follow links.

In this architecture, join the business process management system. Responsibilities of business process management system are that: First, it manage the integration between the various systems, thus avoiding from, a lot of the coupling between the various systems; Second, by tracking order status, complete the order visualization throughout the process.

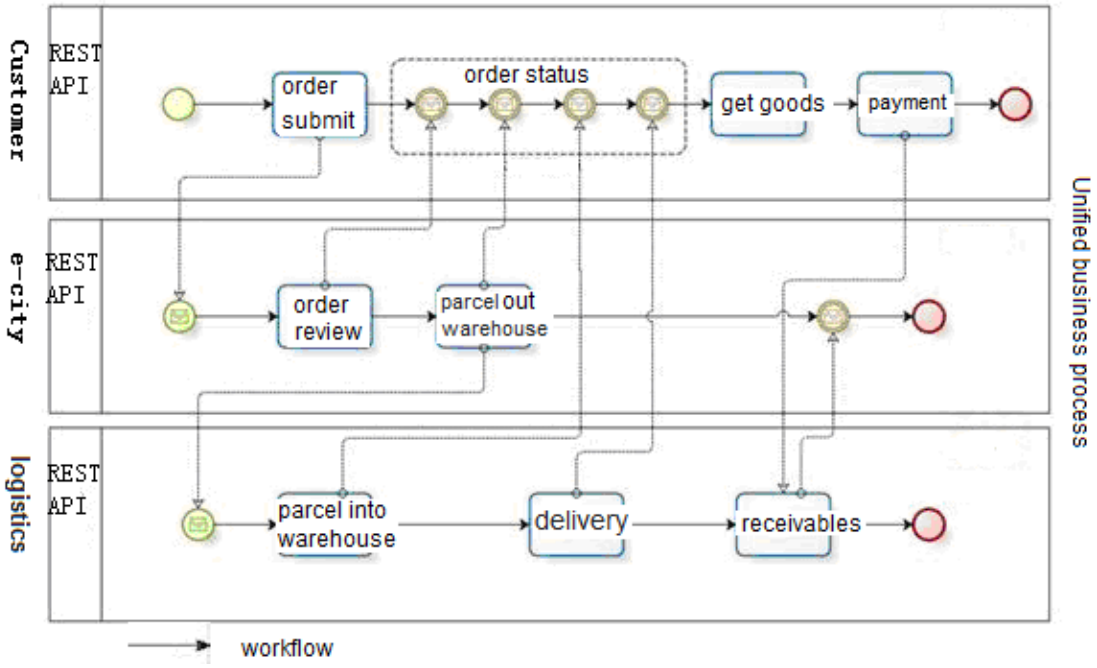

Fig .3. The entire process of orders from submission to completion

Problems and Optimization

REST API follows the model of cloud computing architecture, software architecture based on Web services usually use it for integration purposes via XML or JSON. This means that they are using an Internet browser or Web server.

REST proponents claim that REST request and response data is simple and readable. But SOAP requires a series of complicated encapsulation. Even so, SOAP still can not reach the consistency of the interface; different vendors have their own interface. But REST only uses standard HTTP method. This is indeed the case?

To solve this problem, a WASL (Web Application Description Language) to describe the REST interface. WADL is similar to REST WSDL version , with REST being applied to complex areas ,SOAP is necessary especially for transaction-oriented applications.

Keywords: Finite differencing; Complex-Step Differentiation; precision

Abstract. Finite differencing is a very commonly method used in numerical algorithms to compute derivatives, which is well known for its accurate precision. Besides, the best advantage of this method resides in the fact that it is extremely easy to implement. But the finite differencing may be in a dilemma. The reason is that if the step size is large, the precision is not satisfying, but if the step size is small, the error is increased due to subtractive cancellation. In this manuscript, a new method for differential, complex-step differentiation (CSD) is proposed, which uses complex computations to compute derivatives. We first give a detailed account of the principles of the complex-step differentiation. Then analyze the CSD method from two sides, error and efficiency. At last, the implementation of CSD in MATLAB is presented. Simulating results indicate that they are fitting well with the theoretical analysis.

Introduction

Analytic functions, such as Polynomial functions, exponential functions, trigonometric functions, are very common type of functions in Mathematics [1] [2]. Analytic function differentiations are common operations in mathematical calculations. In computer programs, only Programmable method can be used to compute derivatives approximately. One method that is very commonly used in numerical algorithms to compute derivatives is finite differencing. It is known for being accurate to some extent and extremely easy to implement [3]. However, this approach has an obvious shortcoming: if the step size is large, the precision is not satisfying, but if the step size is small, the error is increased due to subtractive cancellation. For these reasons, Another method was invented, which use Complex calculation to compute derivatives. This method is called CSD(Complex-Step Differentiation) [4] [5]. For there is no finite differencing in CSD, we can make the step size small enough to get satisfactory accuracy. Besides, the efficiency of this method is relatively higher.

In this article, we first give a detailed account of the principles of the complex-step differentiation. Then analyze the CSD method from two sides, error and efficiency. At last, the implementation of CSD in MATLAB is presented.

Principals

Finite differencing formulas are a common method for estimating the value of derivatives, for the different choices of the proximal point, Finite differencing can be divided into forward difference, backward difference and central difference as follows.

Forward-difference formula:

$$f'(x) = \frac{f(x+h) - f(x)}{h} + O(h). \tag{1}$$

Backward-difference formula:

$$f'(x) = \frac{f(x) - f(x-h)}{h} + O(h). \tag{2}$$

Central-difference formula:

$$f'(x)=\frac{f(x+h)-f(x-h)}{2h}+O(h). \quad (3)$$

Whichever the formula is, the truncation error is Inevitable. Theoretically, The smaller the value of step size(h), the smaller the truncation error is. But another problem which called Subtractive Cancellation will appear if the value of step size is too small. Consider function $f(x)=x^2$, now we use finite differencing to calculate the derivative of it at $x=3.253$. If we make the $h=0.002$, here comes:

$$f'(3.253)=\frac{f(3.253+0.002)-f(3.253)}{0.002}=\frac{3.255^2-3.253^2}{0.002}=10. \quad (4)$$

But the Correct value is computed as follows:

$$f'(3.253)=2x\big|_{3.253}=2\times 3.253=6.506$$

Which is much smaller then 10. This is because the step size is too small, as a result, the values of f(x) are very close at the proximal points. A subtraction operation and a division operation used in the process result in a bigger value.

The properties of analytic functions in the complex domain can be used to solve approximate derivation. The method based on these properties is called CSD. Consider analytic function $f(z)=u(z)+iv(z)$, argument $z=x+iy$ is complex. Function f is differentiable in the complex plane, and, we will get the same result no matter we approaching from the imaginary axis or the real axis.

Approach from the real axis:

$$\lim_{\substack{h\to 0\\ h\in R}}\frac{f(z_0+h)-f(z_0)}{h}=\frac{\partial f}{\partial x}(z_0). \quad (5)$$

Approach from the imaginary axis:

$$\lim_{\substack{ih\to 0\\ ih\in iR}}\frac{f(z_0+ih)-f(z_0)}{ih}=\lim_{\substack{ih\to 0\\ ih\in iR}}-i\frac{f(z_0+ih)-f(z_0)}{h}=-i\frac{\partial f}{\partial y}(z_0). \quad (6)$$

$$\frac{\partial f}{\partial x}(z_0)=-i\frac{\partial f}{\partial y}(z_0). \quad (7)$$

Deform Equation (7)，here comes the Cauchy–Riemann equation of function f:

$$\frac{\partial u}{\partial x}=\frac{\partial v}{\partial y}. \quad (8)$$

$$\frac{\partial u}{\partial y}=-\frac{\partial v}{\partial x}. \quad (9)$$

Deform equation (8) using differential forms:

$$\frac{\partial u}{\partial x}=\lim_{h\to 0}\frac{v(x+i(y+h))-v(x+iy)}{h}. \quad (10)$$

h is a real number here. Equation (10) can be deformed as follows Because our concern is the derivative of the function f at some point real number.

$$\frac{\partial f}{\partial x}=\lim_{h\to 0}\frac{\mathrm{Im}[f(x+ih)]}{h}. \quad (11)$$

If h is small enough, the derivative of f can be written as:

$$\frac{\partial f}{\partial x}\approx\frac{\mathrm{Im}[f(x+ih)]}{h}. \quad (12)$$

The equation above is the CSD derivation formula, for there is no differential operation in it, there will be no Subtractive Cancellation. Theoretically, as long as h is small enough, CSD can get a satisfied result.

The function f can be expended as a Taylor series about a real point x as follows and compute the value of f at the point x + ih:

$$f(x+ih)=f(x)+ihf'(x)-h^2\frac{f''(x)}{2!}-ih^3\frac{f'''(x)}{3!}+\cdots \tag{13}$$

Taking the imaginary parts of both sides of this Taylor series expansion and dividing it by h yields:

$$f'(x)=\frac{\mathrm{Im}[f(x+ih)]}{h}+h^2\frac{f'''(x)}{3!}+\cdots \tag{14}$$

Namely:

$$f'(x)=\frac{\mathrm{Im}[f(x+ih)]}{h}+O(h^2). \tag{15}$$

From equation (15) we can see that the Truncation error is $O(h^2)$ if we use CSD to compute the derivative of f, which is much smaller than $O(h)$.

Simulating

In this manuscript, the following expression to show how CSD works as shown in Fig.1 is used and simulating is given below based on MATLAB.

$$F(x)=\frac{e^x}{(\cos x)^3+(\sin x)^3} \tag{16}$$

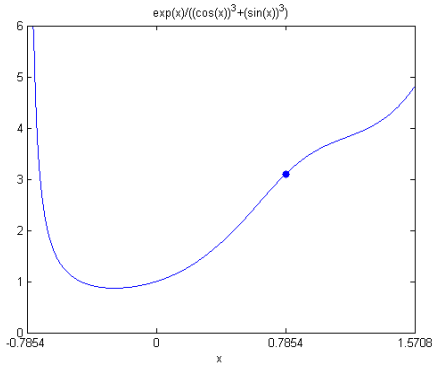

Fig. 1: Schematic of F(x)

In the following, error and efficiency analysis are given. Firstly, for a more accurate analysis of the error of complex-step differentiation, MATLAB symbolic toolbox can be used to compute the exact value of the derivative function. The error curve is shown in Fig. 2.

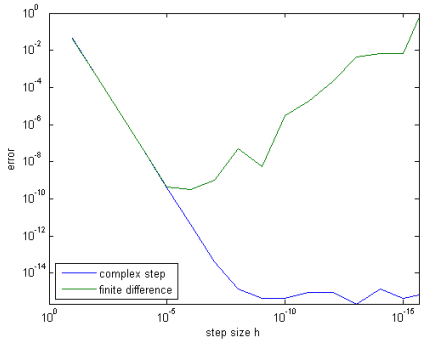

Fig. 2 Error curve of CSD compared with finite differencing

The results are just the same as we expect. The error of CSD is very small when the step h is small enough, but the error of finite differencing will be much bigger for the Subtractive Cancellation when h is too small.

A simple example can be used to show the efficiency of CSD, function f is described as $f=x_1x_2$.

We want to find a first-order partial derivatives for x. the process are shown in table 1.

Table 1 The process of CSD compared with finite differencing

Forward Differencing	Complex-Step Differentiation
$\Delta x_1 = 1$	$h = 10^{-20}$
$\Delta x_2 = 0$	$h_2 = 0$
$f = x_1 x_2$	$f = (x_1 + ih_1)(x_2 + ih_2)$
$\Delta f = x_1 \Delta x_2 + x_2 \Delta x_1$	$f = x_1 x_2 - h_1 h_2 + i(x_1 h_2 + x_2 h_1)$
$\partial f / \partial x_1 = \Delta f$	$\partial f / \partial x_1 = \mathrm{Im}\, f / h_1$

From table 1 we can see that, when the forward difference method is used to derivate, the result is stored in a separate variable x, but when complex-step differentiation is used, the result is stored in the imaginary part of x. CSD derivation using the complex arithmetic, the time used in calculation $x_1 x_2$, $h_1 h_2$ are wasted. So, the efficiency of CSD is Slightly lower then finite differencing.

Conclusions

This manuscript describes a way to compute differentiation using complex computing, named CSD. Before we propose the theory analysis of complex-step differentiation, a commonly used algorithm which is known as finite differencing is analyzed. Besides, the best advantage of this method resides in the fact that it is extremely easy to implement. CSD uses complex computations to compute differentiation. If we make the step h small enough, we can hit satisfactory accuracy. We first introduce the Principles of CSD in two different aspects. Then made comparison of CSD and finite differencing in error and efficiency. The MATLAB program was given at last.

Keywords: Wireless sensor network; Clustering; Routing; Energy

Abstract. This paper proposes an energy-efficient clustering routing algorithm based on the node degree, relative distance between nodes and residual energy. Selecting the cluster head fully consider the node degree and their relative distance. By this way, the coverage performance of cluster head is better and the average distance between member nodes and cluster head is short, so the cost of communication in the cluster is decreased. At the same time, the nodes with low energy have less probability to become the cluster head. Therefore, it can improve the quality of cluster; prolong the life time of the network.

Introduction

The wireless sensor network is composed by larger number of wireless sensor node with low-cost and low-power, which are easy to be deployed, but it can only use batteries which are difficult to be replaced, so how to prolong the network life is one of the hot research topic in WSN [1, 2].In the typical clustering algorithm, LEACH algorithm is one of the most representative clustering algorithms [3]. This algorithm is an adaptive topology algorithm, and periodically performs the cluster reconstruction process. In the process of forming the cluster, the node in network is selected as the cluster head with equal probability; the cluster head selection is random, so it balances the node's energy consumption. However, the random selection mechanism doesn't consider the residual energy of nodes, and can not guarantee the rationality of the number of cluster head nodes and the uniformity of distribution [4]. So people proposes the LEACH-ED protocol on this basis [5], which is based on the distance from cluster head node to source node and residual energy. LEACH-T protocol is also proposed, which use the time interval instead of the generated random number of cluster head and threshold [6]. But these two improved protocols have also not considered the rationality problem of the cluster head node distribution.

This paper proposes an energy-efficient clustering routing algorithm (EECA) which is based on node degree, the relative distance between nodes and residual energy. The algorithm ensures the uniform distribution of cluster head, balance the cluster scale, and select the node with high-energy priority as the cluster head nodes. It can balance the network energy consumption and prolong the network life.

Design of Algorithm

The EECA algorithm uses the wireless communication energy consumption model in reference [7] as foundation. The power consumption of sending data is:

$$E(k,d)_{send} = \begin{cases} E_{elec} \bullet l + E_{fs} \bullet l \bullet d^2, d < d_0 \\ E_{elec} \bullet l + E_{mp} \bullet l \bullet d^4, d \geq d_0 \end{cases} \quad (1)$$

The energy consumption of the receiving data is: $E(k)_{receive} = E_{elec} \bullet l$ (2).

l is the number of bytes of data packets, d is the distance for sending, when the transmission distance is less than threshold d0, the loss of power amplifier use free space model, otherwise use the multipath attenuation model; Eelec(nJ/bit) is the energy consumption coefficient of radio

frequency; Ef and Emp are amplifier circuit's energy consumption coefficient of two kinds of mode respectively.

According to the received signal strength, we can calculate the distance d from the node to the sending node; the formula is described as $d = 10^{|RSSI-A|/(10\times n)}$ (3).

A is the received signal strength whose distance is 1m to the sending node, RSSI is the received signal strength, n is the path attenuation factor, and it generally take 2-5.

EECA algorithm takes the round working way, which likes other clustering algorithm. Each round is divided into the selection of cluster head and the cluster formation and stable operation. First of all, we introduce some definitions; M is used to present the set of all nodes in network.

Definition 1 The neighbor nodes are in M, d(i,j) is the Euclidean distance between any two nodes i and j. If d(i,j)≤Rc, then call node j is neighbor node of node i, Rc is the node's radio radius, the set of neighbor node of node i is presented as Neighbouri.

Definition 2 Node's degree is in M, within the scope Rc of any node i, the number of contained nodes is called the node's degree, which is presented by Numberi. Numberi is more higher, there are more nodes round the node, then the coverage performance of cluster that use the node as the cluster head is better.

Definition 3 After member nodes has completed the cluster head selection process, if node j is in the coverage scope of cluster head node i, the distance between j and i is less than the Rc, then call node j is the member node of the cluster head node i. We assume any node can only be as the member node of one cluster.

In the initial stage, we assume all the nodes in the network have the same clock, the specific implementation steps are as follows:

Step 1: in the information broadcast stage, all the nodes broadcast its own ID information, in this process, node i will count its Neighbouri, Numberi and Ii through the received information.

Step 2, in the phase of decide role, perform the following operations to all the nodes:

(1) Each node computes its own timing time t, after received the information from the base station, and start timing. If the node i has not received the information from the cluster head in time ti, then it announce itself as the cluster head, and broadcast notice to its neighbor nodes.

(2) If the node received the information from cluster head, then it chooses to become as the member node, and exit the timing.

(3) If the node received the information from more than one cluster head, then it chooses to join the cluster that received the information of cluster head later.

ti is computed by following formula:

$$t_i = \alpha \times e^{-w_i} \quad (4).$$

α is the ratio that decide the size of time delay; w_i is defined as following:

$$w_i = 100 \times (C_1 \bullet \frac{1}{d(i)} + C_2 \bullet (1 - \frac{1}{Number_i}) + C_3 e^{E_i}) \quad (5).$$

Ei present the current residual of node i; C1 + C2 + C3 = 1; $d(i) = 10^{|RSSI_i - A|/(10-n)}$. From formula (4) and (5), we can know that the node's degree is higher, the average distance between node and its neighbor nodes is shorter and the waiting time t of node with more residual energy is shorter, then it has more chance to be elected as the cluster head, which can ensures the rationality of selecting the cluster head, and improve the quality of clustering.

Analysis of Optimal Clustering

In order to calculate conveniently, we assume that each cluster has the same number of nodes, N nodes are evenly distributed in the M×M area, two adjacent clusters are no overlap between each other, the expected number of cluster head of whole network meet formula:

$$n\pi R_c^2 \approx M_2 \quad (6).$$

Rc is the optimal value of sensor node's radio radius. When the running of clusters is stable, the energy consumption of cluster head in one in one information transmission process is:

$$E_{CH} = lE_{elec} \bullet k + lE_{BF}k + l(E_{elec} + E_{mp}d_{BS}^4) \quad (7).$$

EBF is consumed by cluster head on a data fusion energy, l is the size of transmission data packets, k is the number of member nodes that are contained in cluster, dBS is the distance from cluster head to base station. During a transmission process, the energy consumption of member node is as follows:

$$E_{NON-CH} = lE_{elec} + lE_{fs} \bullet d_{CH}^2 \quad (8)$$

dCH is the expectation value of distance from the member node to the cluster head. The energy consumption of the whole cluster of sending data to base station once is as following:

$$E_{cluster} = E_{CH} + kE_{NON-CH} \quad (9)$$

We use $\rho(x, y)$ to present the node distribution density in the network; the mathematical expectation of $d2$ is as follows:

$$E[d_{CH}^2] = \iint (x^2 + y^2)\rho(x, y)d_x d_y = \iint r^2 \rho(r, \theta) r d_r d_\theta \quad (10)$$

Replace $\rho = \frac{N}{n} \times \frac{1}{\pi R_c^2}$ into formula (10), and then we get:

$$E[d_{CH}^2] = \rho \int_0^{2\pi} \int_0^{R_c} r^3 d_r d_\theta = \frac{NR_c^2}{n^2} \quad (11)$$

Then in one data transmission process, the energy consumption of whole network is

$$E_{total} = n \times E_{clusterl} \quad (12)$$

Replace (7),(8),(9),(11) into (12), and let $\frac{dE_{total}}{dR_c} = 0$, then we get the minimum network energy consumption

$$R_c = \sqrt[4]{\frac{2M^2(E_{mp}d_{BS}^4 - E_{elec})}{N\pi E_{fs}}} \quad (13)$$

Replace formula (6) into formula (13), then we can calculate the relationship between the number of clusters on ideal state and the parameters of network environment, then we get:

$$n = \sqrt{\frac{N}{2\pi}} \bullet \sqrt{\frac{M^2 \bullet E_{fs}}{E_{mp}d_{BS}^4 - E_{elec}}} \quad (14)$$

Simulation

In order to verify the algorithm's performance, we make the simulation on Matlab platform. 100 wireless sensor nodes are randomly distributed in the area of 100m×100m, the base station is located in the center of the region. According to formula (13), we can obtain the optimal value Rc∈[16,54] of sensor node's radio radius. Here, we take the node's effective radius radio Rc=30m. According to formula (14), under the condition of effective radio radius Rc=30m, the ideal optimal number of clusters n=4. We make simulation experiment 10 times for LEACH, LEACH-T, LEACH-ED, EECA algorithm, and get the mathematical expectation of the number of cluster head in each round, and statistics the distribution of number of cluster head, which is shown in figure 1.

From figure 1, we can know that the generation of cluster head of LEACH and LEACH-ED is completely control by random number and threshold value, so the generation number of cluster head is not stable, and the changing range of the number of cluster head is bigger; The generation number of cluster head of EECA is not only stable, and is more close to the number of cluster head by theory expectation. From figure 2, the cluster head of LEACH algorithm is randomly generated, so it would cause some nodes with low energy act as cluster head and premature death, ad reduce

the network lifetime. Although LEACH-ED and LEACH-T avoid the node with low energy act as cluster head, but the distribution of cluster head is relatively uneven, the size of cluster also doesn't be considered, thus it affect the network lifetime. EECA algorithm avoids the node with low energy act as cluster head node, and considers the relative distance between node and the node degree when selecting cluster head, which balance the rationality and equilibrium of distribution of cluster head. The simulation results show that EECA can prolong network lifetime better.

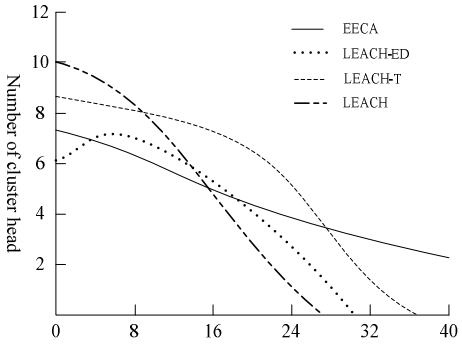

Fig.1 Distribution of number of cluster head

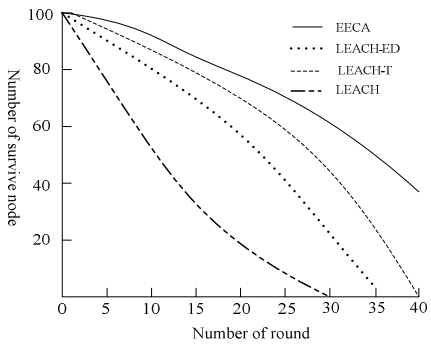

Fig.2 Network's life time of all algorithms

Conclusion

This paper proposes an energy-efficient clustering routing algorithm based on node degree and the relative distance between the nodes. In the process of clustering, the algorithm priority selects the node which has more neighbor nodes and shorter relative distance to neighbor nodes as the cluster head nodes. At the same time, it considers the residual energy of node, the node with lower has lower probability to act as cluster head.

Keywords: DSP Memory Allocation; Knapsack Problem; Greedy Algorithm

Abstract. In practical applications of DSP systems, DSP chips with limited on-chip RAM resources are often chosen to reduce cost. In this condition, part of the codes has to be stored in FLASH or expanded RAM and thus can not run at full speed. This paper presents a strategy of allocating the on-chip RAMs to obtain the maximum system performance. First, the memory allocation problem is described as the knapsack problem, and then the greedy algorithm is applied. Experimental results show that the overall execution efficiency can be improved by 10% when the on-chip RAMs are rather limited. Therefore, the proposed memory allocation method is efficient for low-cost design to obtain higher performance.

Introduction

Digital signal processors (DSPs) with high-speed computing capability have been widely used in multimedia signal processing, mobile communication, intelligent control and other areas. In the design of DSP systems, the selection of chips is based on software and hardware solutions. Computing capability, storage capacity, I/O resources, power consumption and cost need to be considered in selection of DSP chips [1-3]. The mainstream DSP manufacturers provide a variety of DSP chips with different configurations for users. The type and capacity of memories is one of the most commonly used specifications to distinguish different DSP chips, and it is also an important measure of DSP performance. Typically, large-capacity and high-performance memories lead to a high price. In the applications of consumer electronics which are sensitive to the cost, the designer should choose DSP chips with smaller memory capacity under the premise of meeting the system requirements. In addition to optimizing DSP algorithms and codes, reasonable allocation of DSP memories is an important way to reduce the computational complexity of the system. This paper describes a method to improve the execution efficiency of DSP systems via memory allocation based on greedy algorithm. Experimental results show that, for DSPs with limited memory resources, the proposed method can achieve better performance than some other methods.

Memories in DSP System

DSP memories consist of several types, such as DARAM (Double-Access Random-Access Memory), SARAM (Single-Access RAM), XRAM (eXpanded RAM), ROM (Read-Only Memory), FLASH, etc. They have different features of execution efficiency, read/write property, volatility, and usage, which are summarized in Table 1 [4]. On-chip DARAM and SARAM have the best efficiency for executable codes, but the contents will be lost when the power is off. Contrarily, ROM and FLASH are non-volatile, but their efficiency is limited in high-speed systems. Generally, the executable codes are usually stored in FLASH or ROM, and are loaded into the on-chip RAMs at startup to obtain higher efficiency. However, RAMs have higher cost than ROM or FLASH of the same capacity, and thus low-cost solutions prefer to use the DSP chips with limited on-chip RAMs. Therefore, to achieve the best system performance, the available on-chip RAMs should be fully allocated and utilized.

Table 1 Typical types and features of DSP memories

Type	Execution efficiency	Contents	Read	Write	Non-volatility
DARAM	0.5 cycle/instruction	program, variable stack	√	√	×
SARAM	1 cycle/instruction	program, variable stack	√	√	×
XRAM	4 cycles/instruction	program, variable	√	√	×
FLASH	2 cycles/instruction	program, constant	√	×	√
ROM	2 cycles/instruction	bootloader, vector table	√	×	√

DSP Memory Allocation Strategy and Method

When the prototype of DSP algorithms is transplanted into the DSP platform, allocation of data and program space needs to be considered. The quality of storage space allocation will directly affect the execution efficiency of the algorithms. For DSPs with enough on-chip RAMs, memory allocation is not a problem; but it is critical for DSPs with limited on-chip high-speed RAM resources which are adopted for low-cost solutions. In this condition, reasonable allocation of on-chip RAMs is important to the overall system performance. Generally, this problem can be stated as minimizing the overall computational complexity by allocating the executable codes into the on-chip RAMs with limited capacity. It can be treated as a knapsack problem that is commonly used in production scheduling, resource allocation and investment decision.

1) Knapsack problem

Knapsack problem can be generally described as below:

Given n items' weights $w_i\ (w_i > 0)$ and values $c_i\ (c_i > 0)\ (i = 1, 2, \cdots, n)$, and given a knapsack whose capacity is limited to $V\ (V > 0)$; then, put some items into the knapsack. The problem is that how to choose the items to obtain the maximum overall value while not exceeding the knapsack capacity. Assume that each item is inseparable and can be chosen only once, the 0-1 knapsack problem can be formulated as the following maximization problem [5]:

$$\text{Maximize} \quad f(x_1, x_2, \cdots, x_n) = \sum_{i=1}^{n} c_i x_i \tag{1}$$

$$\text{subject to} \quad \begin{cases} \sum_{i=1}^{n} w_i x_i \le V \\ x_i \in \{0,1\} \end{cases} \quad (i = 1, 2, \cdots, n) \tag{2}$$

where x_i is the decision variable. When $x_i = 1$ the ith item will be loaded into the knapsack, and when $x_i = 0$ it will not.

2) Knapsack problem of DSP memory allocation

The DSP memory allocation problem in this paper can be treated as the 0-1 knapsack problem and described as below.

Assume that a project contains n code sections with code size $L_i\ (L_i > 0)$ and computational complexity $c_i\ (c_i > 0)$, $i = 1, 2, \cdots, n$. Choose some code sections and allocate them into the internal RAM to improve their execution efficiency. The target is to minimize the overall computational complexity under the condition that the available internal RAM size is limited to $V\ (V > 0)$. Similar to (1), such optimization problem can be expressed as

$$\text{Minimize} \quad f(x_1, x_2, \cdots, x_n) = \sum_{i=1}^{n} c_i x_i \tag{3}$$

$$\text{subject to} \quad \begin{cases} \sum_{i=1}^{n} L_i x_i \le V \\ x_i \in \{0,1\} \end{cases} \quad (i = 1,2,\cdots,n) \tag{4}$$

where x_i is the decision variable.

3) Greedy algorithm for DSP memory allocation

Greedy algorithm is one of typical methods to solve knapsack problem, which has been applied in many applications [6-7]. By using its principle, first, define the efficiency density of each code section as $\rho_i = c_i / L_i$; then the code section with larger density has higher priority to be assigned into the on-chip RAMs. Detailed steps are described as follows:

a) For all n code sections, calculate their efficiency density denoted by $\rho_i = c_i / L_i$, $i = 1, \cdots, n$.

b) Sort ρ_i in descending order and obtain the corresponding queue of indices $q(k) \in \{1, \cdots, n\}$, where $\rho_{q(1)} > \rho_{q(2)} > \cdots > \rho_{q(n)}$.

c) Set $k = 1$ and $x_i = 1 \, (i = 1, \cdots, n)$.

d) If $\sum_{j=1}^{k} x_{q(j)} L_{q(j)} \le V$, the code sections corresponding to $q(k)$ is assigned into the on-chip high-speed RAMs, i.e. $x_{q(k)} = 1$; then set $k = k + 1$ and go to step d). Otherwise, set $x_{q(k)} = 0$ and go to step e).

e) Find in $\{q(k+1), \cdots, q(n)\}$ the first one that satisfies $\sum_{j=1}^{k-1} x_{q(j)} L_{q(j)} + L_{q(l)} \le V \ (l > k)$, and set $x_{q(l)} = 1$, $x_{q(k+1)} = x_{q(k+2)} = \cdots = x_{q(l-1)} = 0$, and $k = l + 1$. Then go to step d), and repeat the above procedures until all n code sections are examined.

Test Case and Experiments

The DSP applications can be developed in TI CCS integrated environment, and the code information can be analyzed through its profile function. The information given by the profiler is shown in Table 2 [8].

Table 2 Profile information

Address Range	Symbol Name	Symbol Type	Access Count	CPU Cycles: Incl. Total	CPU Cycles: Excl. Total
$A_{start} - A_{end}$	$function_x$	*function*	$N_{\text{access_cnt}}$	$N_{\text{cycle_in}}$	$N_{\text{cycle_excl}}$

In Table 2, A_{start} and A_{end} are the start and end addresses, respectively; $function_x$ is the code name, where *function* indicates that the code type is function; N_{access_cnt} is the number of executions of $function_x$; $N_{\text{cycle_in}}$ is the total number of CPU cycles of $function_x$, including the subroutines; and $c_i = N_{\text{cycle_excl}}$ is the total number of CPU cycles of $function_x$, excluding the subroutines. Each code size L_i and efficiency density ρ_i used in the proposed method can be calculated as follows:

$$L_i = A_{end} - A_{start} \tag{5}$$

$$\rho_i = N_{\text{cycle_excl}} / (A_{end} - A_{start}) = N_{\text{cycle_excl}} / L_i \tag{6}$$

The test case is a smart home control procedure developed on TMS320F2811 platform [9]. The proposed method was applied in DSP memory allocation to minimize the total computational complexity. First, the storage information was analyzed. The on-chip SARAM capacity of F2811 is 36 KBytes, but the test case requires at least 60 KBytes. Thus the allocation of SARAM should be optimized. Then the profile statistics in Table 2 was generated by using CCS, and L_i, c_i and ρ_i were calculated. Finally, the proposed method was performed to assign each function into SARAM or FLASH. The computational complexity versus the available size of SARAM is shown in Fig.1, including the comparisons with some other methods.

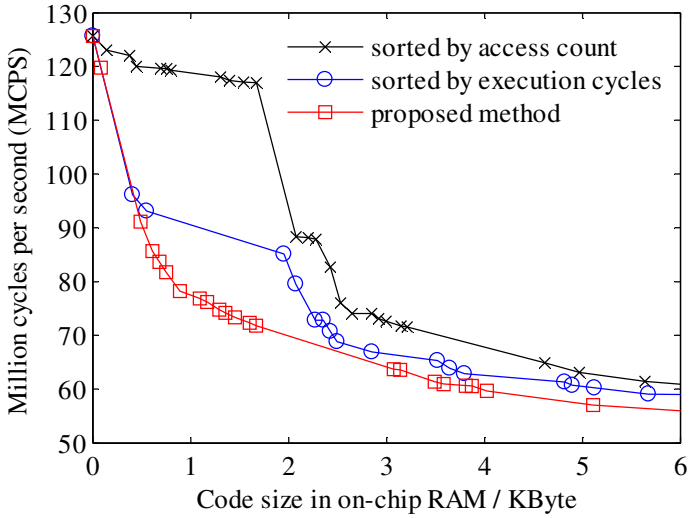

Fig.1. Computational complexity vs. code size in on-chip RAM for different methods

Fig. 1 shows three curves, where □ denotes the allocation method by using the proposed greedy algorithm; ○ and × correspond to the methods of sorting the code sections by access count and by execution cycles, respectively (both in descending order). The code section with a larger access count or execution cycles has a higher priority to be assigned into the on-chip RAMs. The results show that, with the same available RAM size, the proposed method can achieve a lower computational complexity. It makes the overall complexity decrease more rapidly as the occupied RAM size increases. This indicates that the proposed method can improve the execution efficiency of the system by effectively utilizing the on-chip full-speed RAM resources. This scheme can improve the system efficiency by up to 10% higher than the other schemes for the DSP chips with rather limited available on-chip RAM resources (such as several KBytes). Therefore, the proposed method is more suitable for low-cost DSP applications.

Conclusion

To improve the performance of DSP systems with limited on-chip RAM resources, this paper presents a method to allocate the memories by using greedy algorithm. Experimental results show that, for DSP chips with limited on-chip RAM resources, the proposed method can achieve better execution efficiency than some other methods. With the help of the design tool chain of DSP systems, this method is simple and feasible to implement. Therefore, it could be an efficient approach to low-cost DSP solutions.
